SUMMARY.

Mr. Raymond E. Crowther, in a contributed article, reviews some of the attempts which have been made in the past for desensitising of exposed plates as a means of developing in actinic light, and describes at length the results of the investigations of Dr. Lüppo-Cramer, according to which bathing with phenosafranine dye makes of development without a dark-room a readily practicable process. (P. 3.)

MM. Lumière and Seyewetz, in a short communication, give formulæ which they have worked out for quinone bleaching baths for the conversion of developed silver images into silver chloride or bromide. (P. 6.)

In a leading article we emphasise a few of the things which the beginner in studio lighting needs to keep before him in his study for proficiency in this art. (P. 2.)

Formula for the copper reducer, worked out by Mr W. J. Smith as a substitute for the costly and poisonous iodine-cyanide, will be found on page 7.

Other "Assistants' Notes" relate to vignetting and spotting. (P. 7.)

At the Royal Photographic Society, on Tuesday evening last, Mr. N. E. Luboshez gave a striking demonstration, by means of lantern slides, of the possibilities of "straight" lighting in photographic portraiture. (P. 9.)

The annual exhibition of apparatus and novelties for professional photographers, held by Messrs. Waltuch Smith, included this year a number of new introductions. (P. 10.)

A French contemporary has begun the publication of systematic abstracts of photographic literature. (P. 1.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Mr. E. J. Wall, in a contributed article, makes an addition to the past literature of colour photographic processes, by quoting from the book issued in 1856, in which the Rev. L. L. Hill describes the method of direct heliochromy, which has been hitherto little known under the name of "Hillotype." (P. 1.)

Mr. F. E. Ives sends us revised formulæ for the bleach employed by him in the mordanting dye process, which he has continuously investigated during the last twelve months. He now uses a mixture of ferricyanide, bichromate and acetic acid. (P. 3.)

Some notes from a German source on the ill-fated career of Louis Ducos du Hauron have recently emphasised certain passages in the French inventor's life, which point to the year 1862 as that of his origination of three-colour processes. (P. 4.)

A French writer recently advocated the Simmen method of hypersensitising Autochrome plates as the most suitable for these plates as now made. (P. 4.)

EX CATHEDRA.

Fine Art Prints!

We note the appearance in the fine art publishing trade of prints from photographic originals in the shape of a series of semi-nude studies professing to illustrate the seasons. We have no desire to discourage such enterprise as this, which obviously opens still another avenue for profitable exploitation by photographers, but we cannot disguise a sense of disappointment that among so much that is of real pictorial merit the resort should be to work into which Art enters in insignificant proportion. We shall be told that "art" publishers must produce what the print shops can sell; and the argument is a sound one, for no one who takes a glance over the output of the fine art trade can have many illusions as to the kind of work which commands "big business." The print sellers, again, with equal correctness can pass the responsibility on to the shoulders of a tasteless public. Yet, when all this is admitted, there is still the occasion to plead that photographic works of real artistic merit should be given a chance. To deny that proposition is to relegate photography to an altogether inferior category, from which it will be still more difficult, as time goes on, for it to extricate itself.

* * *

Bibliography.

If the bibliographical treatment, which photography has received during the past few years—and is to receive upon a still more systematic plan—is maintained as years go by, the searcher of the future for any given item of investigation will have a very much easier task than in the past. The Monthly Abstract Bulletin, originated by Dr. Mees, and now in its seventh year of issue, has led the way in this respect. Although designed for the specific purposes of the staff of the Eastman Research Laboratory, and therefore planned upon a system which perhaps would not be that of a bibliographical work for general publication, it is, nevertheless, a valuable means of enabling anyone to know what is being published from month to month. We note also that in its issue of January 1 our contemporary "La Revue Française de Photographie" is issuing a supplement in the form of a sheet of abstracts, which present in an abridged form papers from the photographic and scientific press relating to photography and also notable patent specifications. The preparation of this supplement is in the capable hands of M. L. P. Clerc, to whose constant and expert labours those in France and in French-speaking countries are indebted for a knowledge of progress in other countries. But it is expected that in point of comprehensive range and scientific classification the "Abstracts Journal," to be issued by the Royal Photographic Society under the management of the Scientific and Technical Group, will leave little to be desired, and will provide the student, investigator or historian with an exact survey of the photographic and

photo-chemical literature of all countries, and will render easy the means of referring to the original of any given paper or communication.

* * *

Wanting It Both Ways. Not so very long ago we were taken to task in the German photographic press for venturing to suggest that few important original discoveries in photography had originated from the Central Empires. We were told that primitive people could think of an idea, but it required the genius which flourishes on the other side of the Rhine to make it of value; which, of course, contains an element of truth, but is not an answer to what we pointed out. Now, in a recent issue of "Photographische Korrespondenz" we observe an ex-enemy writer arguing precisely the other way about. It appears that the very beautiful device for soft focus effects embodied in the Eastman projection printer and worked out by Mr. C. W. Frederick, of Rochester, had its origin with a Herr Lenhard, who, in 1890, described glass plates etched in spiral or star pattern for this purpose. All we can say is that this original discovery has lain remarkably dormant for many years. According to the view which we have already quoted, the credit must be given to Mr. Frederick. We have become accustomed to the tortuous mentality which characterised much German propaganda; and it seems that this latter continues to display itself in respect to questions of technical invention.

THE STUDY OF LIGHTING.

The novice in portraiture can be excused for feeling somewhat bewildered when he visits an exhibition of modern photographs in the hope of learning something about the art of lighting the human subject. Usually, he will find such a variety of treatment that he will be led to the opinion that lighting is almost a matter of chance, and that what he had best do is to expose his plates under almost any conditions and trust to luck for the result. Such a conclusion would, however, prove fatal to his own prospects of turning out consistently good work, for though he might occasionally "fluke" a success, the lack of knowledge would prevent him from repeating it with such modifications as would be necessary with another sitter. Therefore, the beginner must learn to control his light. He must start on the simplest styles, and when these are mastered attempt those which are more ambitious.

Although servile copying of a style, whether it be that of a photographer or a painter, is to be deprecated in work which is to be shown to the public, it is invaluable to the student, whom we strongly advise to procure such portraits as appeal to his taste. Selecting, as sitters, such of his friends as have some resemblance to the originals, let him endeavour to produce something as nearly approaching his model photographs as possible. It is not to be expected that success will attend the first effort, but repeated attempts should be made until a near approximation is arrived at. Some of these attempts may appear more pleasing to the photographer than the original model, but they must be laid aside until the purpose aimed at, that of reproducing a particular effect, has been achieved. Such practice with various styles of lighting will rapidly bring a confidence and facility in working which could not be attained by years of unsystematic work.

To come to practical details of lighting, it should, in the first place, be understood that, provided a sufficient volume of light is available and can be made to fall upon the sitter at any desired angle, the actual design of the studio is of little consequence; moreover, that any effects obtainable by daylight can be equally well obtained by an efficient electric installation. Apart from the direction of the light, one of the most important factors is the distance between the light and the sitter, the lighting becoming softer the farther the sitter recedes from the light. This is most apparent with a light of small area, such as a single enclosed arc lamp, of course, properly screened, but it can easily be demonstrated with daylight (care being taken that the angle of the light is not altered) by placing the sitter at distances of four and seven feet from the light side of the studio, and if possible taking negatives at both positions. It may be useful to point out that the eye requires a good deal of training to appreciate variations in lighting, as it is necessary to ignore the effect of colour; negatives, being monochromatic, give a safer basis for comparison. A bust painted grey or buff is useful for experiments in lighting, or green or blue spectacles may be used to eliminate the colour factor. For the same reason it is not desirable to judge of lighting by inspection of the camera screen, since the effect, owing to the reduced size and the presence of colour, appears satisfactory in almost all cases.

Comparatively few photographers appreciate the value of translucent and semi-opaque screens which are used close up to the sitter. Many lighting problems which are extremely difficult of solution if the ordinary blinds are available, are very simple if local shading can be done. A couple of ordinary head screens, covered, one with butter muslin and the other with a thin dark material, should always be at hand; the latter is particularly useful to reduce the light on white drapery or to throw the hands into semi-shadow.

Reflectors should be sparingly used, and should be introduced only to obtain such effects as cannot be produced by direct lighting. This does not, of course, apply when the reflector is used as the principal source of light, as when the light of an arc lamp is directed upon a white screen, no direct rays reaching the sitter. In most studios white reflectors are *de rigueur*, and some careful portrait photographers whiten them frequently. At the same time we suggest the occasional use of a light-grey reflector, which, while it softens the shadows, does not betray its use, and is certainly less liable to give cross lights in the eyes. Another point in using reflectors is worth noting. If they are brought forward there is a tendency to destroy all the modelling on the shadow side of the face, but if kept well back, so that the front edge is level with the sitter's ear, there will be no risk of double lights in the eyes, and the delicate shadows in the face will be preserved.

One more hint. When arranging for strong effects in lighting, it is desirable to admit a fair amount of light at the farther end of the studio. This illuminates the whole subject with a very subdued light, which is much to be preferred to reflected light, from the small source of light which is actually producing the picture.

Holy Trinity, Hull.—A history of the parish church of Hull, by the Rev. G. J. Jordan, reaches us from the Oxford University Press. Apart from its story of an edifice which dates to at least 1182, the volume has an interest for us and, we are sure, for many of our readers, from the fact of its illustration throughout by photographs taken by Mr. T. C. Turner, of Hull, to whose kindness and generosity the author expresses his special indebtedness. One photograph, of the nave with the congregation standing during a service, is an instance of Mr. Turner's resourcefulness in architectural as in other branches of photography.

A PRACTICAL METHOD OF DEVELOPING WITHOUT A DARK-ROOM.

Although much has already been done to "lighten our darkness" in the dark-room by the introduction of gaslight emulsions and the study of the spectral sensitiveness of the various sensitive materials handled by the photographer—the outcome of such study being the excellent series of safelights which are rapidly displacing the once popular ruby glass and canary fabric of the dark-room lamp—it cannot yet be said that the average dark-room is a place in which one would care to spend one's leisure time.

Generally, the illumination is too feeble to allow of comfortable vision; the reading of labels on bottles, for example, necessitates an inspection close to the source of light and, what is perhaps worse, the dirt, which "the eye doesn't see, the heart doesn't grieve over" until an expensive negative is ruined by such "dirt." All too frequently the trinity which holds sway in the room where development is conducted is "Darkness, dirt and disorder." But "Progress," the heretic who cares naught for the prerogatives of established deities, is at work, and the time is not far distant when the so-called dark-room will be the most comfortable and inviting room in a photographic establishment. Indeed, for those who care to avail themselves of the latest discoveries, one may say that the day of the really light dark-room has arrived.

It often happens that those to whom information would be of most practical value have not the time or the convenience or perhaps the ability to assimilate such information and put it to the test of practice. This unfortunate state of affairs is, of course, not confined to the particular branch of industry in which we photographers are interested, but we cannot legitimately place that fact on the credit side of our scientific balance-sheet. In a measure we are ourselves responsible for the general failure to take immediate advantage of the published results of technical research of first-rate importance, for we cherish an obstinate conservativeness, and are all too loth to "try out" the "new thing." Contrast this state of affairs with the national spirit of America, where the quality of "newness" is considered a merit, and one realises at once the mainspring of the phenomenal rate of progress of the American. On the other hand, it would be unfair to accuse the young men of our profession of undue laxity, because they show but little inclination to unravel the reports on technical research which appear from time to time scattered throughout the various scientific journals and proceedings of learned societies. Unfortunately, in many cases scientists live with their heads in the clouds, and their utterances are couched in anything but lucid language, making the possession of a scientific education a necessity to the understanding of their effusions. The assistant therefore who intends to progress finds himself compelled to devote most of his leisure to irksome study. Once the elementals of chemistry, physics and mathematics have been mastered, however, it is surprising how easily the results of many researches can be assimilated and put into practice. For the comprehension of many researches fortunately no special scientific knowledge is necessary, and if the interest of chronological evolution is added in the presentation of the results the subject often becomes really fascinating.

"But what has all this got to do with the abolition of the dark-room?" may be asked. Everything; for one of the most interesting pieces of research has just led to results which enable one to have such a light in the dark-room that one may read the newspaper—or the "B.J.," if preferred—whilst developing the modern high-speed panchromatic plate in an uncovered dish.

It is a pity that the work which has led to so remarkable a result is that of a man who had not the good luck to be born an Englishman, for the circumstance that he was numbered amongst our late enemies is sufficient to prejudice many minds against his conclusions, and whilst one cannot but excuse such prejudice to a great extent, one rejoices that the average Englishman—sport that he is—very soon appraises his opponents' achievements at their true value, and commends where praise is due just as heartily as he condemns where condemnation is due. And now having cleared the air, let us begin at the beginning, and we shall see how simple research really is.

In 1898 Mercier was granted a patent for a process of correcting over-exposure effects. The process comprised a bathing of the plate in dilute solutions of various substances, including several of the well-known developers, with subsequent drying.

This patent attracted the attention of Lüppo-Cramer, who made tests under varying conditions of the substances referred to, and in 1901 published his conclusion that the major effect of the patented process arose from desensitisation of the emulsion by the solutions employed. He found that the specified substances desensitised to different degrees, but that generally with developers of the para-amino-phenol class the destruction of the original sensitiveness was of such an order that a plate bathed in a normally constituted developing solution could be exposed with impunity to a light which would fog a similar plate not bathed in developer. Here the matter rested for some time whilst other workers were endeavouring to facilitate development in actinic light either by the addition to the developing bath of dyes which would screen the plate from harmful light, as exemplified by the process patented by Ludwig in 1901 and that recommended by Lumière and Seyewetz in 1903, or by conversion of the silver bromide into iodide as suggested by R. Freund in 1909, and later modified by F. F. Renwick (1920).

Interest in the desensitisation aspect of the matter was revived in 1907, when Lumière and Seyewetz confirmed Lüppo-Cramer's results, and made the observation that mere wetting of a plate with water considerably reduced its sensitiveness. Lüppo-Cramer immediately returned to the subject, and found that whereas only a very slight diminution of sensitiveness resulted from the wetting of a plate, the desensitisation caused by immersion in certain developing solutions was quite marked with many types of emulsion, and, further, that the addition of sulphite to the developer powerfully inhibited the reduction in sensitiveness.

Continuing his work, and varying the developers and the methods of compounding their solutions, it was found that the greatest depression of sensitiveness was caused by dilute plain water solutions of amidol, triamino phenol, triamino benzol and triamino toluol in the form of their commercial salts—the hydrochlorides. Using a 0·05 per cent. solution of these compounds, for example, it was established that the sensitiveness fell, on bathing a plate for one minute, to one two-hundredth of its original value in the case of amidol, and as low as one six-hundredth of its original value in the case of triamino toluol hydrochloride. This led at once to a practical method of developing ultra-rapid non-colour sensitive plates in bright yellow light, all that was necessary being a preliminary bathing in the dark for one minute in a 1 2,000 solution of, say, triamino toluol hydrochloride. Thereafter the plate may be lifted from the solution in bright yellow light and developed by inspection in a light sufficiently powerful to fog wet slow bromide paper rapidly.

But in these days of the more or less common employment of ortho-, screened ortho-, and panchromatic plates the matter could not be allowed to rest at this stage of incompleteness, and it became necessary to find a substance which would desensitise these varieties of plates and render their development by inspection a feasible proposition.

The happy spirit of co-operation which is the mark of scientific workers in every country placed at Lüppo-Cramer's disposal the range of products manufactured by the German dye-making firms, and knowing what type of substance was likely to be of service by reason of its chemical constitution, it was not long before the problem was solved. The final choice was made of the dye known as phenosafranine, and the effectiveness of this body is such that for the development of non-colour sensitive plates in a yellow light bright enough to allow of the comfortable reading of newsprint at two yards' distance from the light, it is only necessary to replace one-tenth of the water used in making up one's favourite developer with an equal volume of a 1: 2,000 solution of the dye, and screen the plate from the light during the first half minute or so in the developer. An easier method, one which will no doubt commend itself to the English worker, and which is applicable with complete success to panchromatic plates, is the following:—

In the dark the plate is immersed in a 0.05 per cent. solution of the dye, and any time after one minute's immersion it may be removed therefrom in bright yellow light—or even by the light of a candle or oil lamp at a distance of 5 to 6 ft., and developed by inspection. The plate may be lifted from the developing solution and inspected by transmitted light with impunity, a circumstance which indicates that the action of the dye is not simply that of a screen serving to cut off harmful light. As a matter of fact, one minute's immersion of a dry fixed out plate in the 0.05 per cent. solution of the dye stains the gelatine a bluish shade of red which, when examined by the spectroscope, is found to transmit the whole visible spectrum, only partially absorbing a short section at the junction of the blue and green. The worker who develops continuously will place his plates in the dye solution contained in a tank and remove them as he is ready for developing them, being unconcerned whether he is dealing with an ordinary, ortho', or panchromatic emulsion.

It may be objected that the dark-room is not entirely abolished and that the process offers no advantages over the method of bathing the plate in the dark before development with a dilute solution of potassium iodide, as recently recommended by F. F. Renwick, but a moment's consideration will convince one that the new process marks a real advance, for the immersion of the plate in the dye solution necessitates only a dark cupboard or recess, and can be undertaken by the least skilled hand in the workroom.

As far as comparison with the potassium iodide process is concerned, it is only necessary to recall that, in addition to the disturbance of the density obtainable, it is necessary to remove the potassium iodide by washing in the dark, to use special developing solutions, and a potassium cyanide fixing bath, and contrast these conditions with those of the phenosafranine process, to rate the latter at its true value. In the new process there is no disturbance of the plate's characteristics; no washing after the one-minute immersion in the dye solution is called for; any developer may be used according to the particular fancy of the operator or the demands of the subject, and the usual hypo bath suffices for fixing. Further, the phenosafranine treatment considerably reduces the amount of chemical fog frequently encountered on panchromatic plates.

In one respect it is unfortunate that the most powerful desensitiser so far discovered happens to be a dye which, by virtue of its chemical constitution, tenaciously stains the gelatine. Somewhat prolonged washing in running water is necessary for its complete removal. This is not an uncompensated drawback, however, for one can be certain that when the film is washed free from dye it is also free from hypo. In cases where prolonged washing with water is inconvenient there are two methods available for hastening the operation. The first is to treat the developed, fixed and approximately hypo-free plate with a bath made by mixing equal volumes of a 2 per cent. alum solution and a 5 per cent. hydrochloric acid solution. The latter solution can be readily prepared by diluting one volume of the commericial acid with six volumes of water. The action of this bath depends upon the decomposition of the gelatine-dye complex by the acid, the strength of which is sufficient to act adversely on the gelatine unless the latter is protected—hence the use of the alum. Two or three two-minute changes of this bath allows of the removal of the dye by short subsequent washing. The second method of shortening the wash is the treatment of the hypo-free plate with a dilute solution of nitrous acid, whereby the dye is converted into a bluish violet compound which possesses but little affinity for the gelatine. The nitrous acid solution is conveniently prepared by dissolving five grains of sodium nitrite in two ounces of water and adding thereto ten minims of commercial hydrochloric acid. A four- or five-minutes' treatment with this bath should allow of a colourless film being obtained after five minutes' subsequent washing. In the writer's experience, the removal of the dye by simple water washing is preferable to either of the "short-cut" methods, and of these latter he prefers the acid alum treatment.

The dye with which Lüppo-Cramer carried out his research was the chemically pure product, and the writer has confirmed all his conclusions when using a sample of the same substance. This product in its pure form is not, however, an article of commerce, but the writer believes that a well-known firm of plate makers is about to place on the market a dye which exhibits all the desirable characteristics of pure phenosafranine. Further experiments are being made by the writer, details of which, together with an account of some remarkable actions of the dye-impregnated plates on developers, must be held over for a further communication. In the meantime it may be noted that the process is not protected by any patent, and since the staining of the film in no way interferes with inspection of the developing image—the suppression of tendency to fog actually facilitates critical observation—it is to be anticipated that the process will rapidly become popular.

RAYMOND E. CROWTHER.

A CRITIQUE OF MR. RENWICK'S THEORY OF THE LATENT IMAGE.

(A Communication from the Research Laboratory of the Eastman Kodak Company.)

In view of Mr. Renwick's recent letter to the "British Journal of Photography" on "Colour Sensitising by Mineral Salts,"[1] it appears that some discussion of his very interesting contribution to the theory of the latent image will be in order. The essentially new element of this contribution consists in the suggestion that, assuming preformed dispersoid silver in solid solution in the silver halide due to ripening, "it is this dissolved silver which first undergoes change on exposure to light."[2] The change effected is supposed to be a conversion of the originally very highly dispersed form to a more condensed one, "the gel or electrically neutral form of colloid silver being regarded as the germ or catalyst required to promote development."

Mr. Renwick now regards his results on the chromatising effect of potassium iodide and cyanide solutions,[3] as also the

1. "B.J.," December 3, 1920.

2. "Photographic Images, Visible and Invisible," by F. F. Renwick (the Hurter Memorial Lecture), "J.S.C.I.," *39*, 156 (1920).

3. "B.J.," November 19, 1920.

[illegible] described by Messrs. [illegible] supporting this theory, the [illegible] advanced that the preformed [illegible] bromide (Ag Br) retains [illegible] sensitiveness, so that [illegible] formed.

Before discussing [illegible] latent image itself, [illegible] stand or fall with this [illegible] as a consequence [illegible] hypothesis, leading back [illegible] and subsequently improved [illegible] solid solutions are formed [illegible] discussed by Lippmann, [illegible] and, though not necessarily [illegible] does not, necessarily [illegible].

With regard to the [illegible] from desensitization [illegible] ments by Mr. [illegible] Bullock were known to [illegible] Hence, the apparent [illegible] plete darkness throughout [illegible] physical development [illegible] of a red [illegible] re-aggregation or re-distribution [illegible] explanation of these effects [illegible] long hypothesis. It is evident [illegible] with Lippmann's [illegible] ing idea [illegible] mechanism [illegible] (KI) reacts [illegible] iodide (AgI), [illegible] some silver bromide (Ag Br) [illegible] admitted), yet both can effect a [illegible] sense. Again, in the Captain-Bullock effect [illegible] action is not brought about by [illegible] (neutral to alkaline) solution, [illegible] bisulphite (AgHSO$_3$) or H_2O [illegible] an alkaline bath, etc. Obviously [illegible] to the "Silver Bromide Grain" [illegible] and myself, I have provided [illegible] silver latent image and failed [illegible] and so autocatalytic in character [illegible] to us, since 1917. [illegible] follows:—First, a [illegible] to solid silver, followed by [illegible] ions, which are known to [illegible] ions favour reversal. But [illegible] of this hypothesis, it [illegible] theory. It seems to [illegible] peculiar effects to [illegible] may be wholly accepted [illegible] an developed silver for [illegible] promising.

The [illegible] original [illegible] ing, [illegible] to criticism [illegible] (sol. to gel [illegible] to be a [illegible] of ultramicroscopic [illegible] visible particles [illegible] there appears [illegible] effected in solid [illegible] potassium iodide [illegible] itself more [illegible] luminous [illegible] also effected by light. In [illegible] Nordentroem may be [illegible] of light [illegible] exhibit [illegible]

4. "B.J. [illegible]
5. "J. Am. [illegible]
6. Lehmann, physik. [illegible]

possible differences in dispersity.[7] If I may be again permitted to refer to unpublished work I should like to note in this connection a possibility, discussed in the monograph cited, as to phase sensitising, as distinct from frequency-sensitising. By this is to be understood the possibility of an optical resonance (photo-chemical) effect being enhanced for any frequency region by regularising, or harmonising, the phase of the incident light waves.

This hypothesis is susceptible of testing by comparison of the photographic effect of illumination differing in respect of the phase harmony (coherence) of the vibrations, but having the same average energy. The statement by Slade and Higson[8] in a recent paper that the same total light energy distributed over a wide spectral strip is less effective than that amount concentrated in a narrow strip requires confirmation before it can be considered in terms of this hypothesis.

Another debatable point is the function of gelatine. It may be that the colloid silver theory assigns too much of a secondary rôle to the gelatine, as simply furnishing colloid silver; there is evidence, to be brought forward later, that the silver bromide emulsion is not only a dispersion of silver halide in gelatine, but also of gelatine in silver halide.

To sum up, I do not feel convinced that Mr. Renwick's hypothesis as to the latent image is adequate, but it is certainly a valuable positive contribution to the theory, and may contain a considerable part of the truth.

S. E. Sheppard.

7. The bearing of change in dispersity on developability will be discussed by Mr. Trivelli and the writer in a forthcoming article.
8. "Proc. Roy. Soc.," A98, *154* (1920).

QUINONE AND OTHER OXIDISING AGENTS FOR THE CONVERSION OF SILVER IMAGES INTO BROMIDE OR CHLORIDE.

The conversion of the silver of silver images into silver chloride, and particularly into silver bromide, is frequently employed in several photographic operations. The process may be carried out by employing either the perchlorides or perbromides of certain metals, or mixtures of halogen acids (or their alkaline salts) with various descriptions of oxidising agent. The methods of conversion into chloride or bromide by means of these various agents may be classified, according to their mode of action, as follows:—

(1) Solutions containing chlorine, bromine, hypochlorites or hypobromites, producing chlorine or bromine in a form capable of acting upon the silver of the image, e.g.:—

Chlorine water.
Bromine water.
Hypochlorites.
Hypobromites.

(2) Chlorides or bromides of metals, in which salts part of the chlorine or bromine acts upon the silver of the image (which functions as a reducer) and produces the soluble chlorides or bromides of the metal in a lower state of oxidation which do not enter into the composition of the image. The following compounds are utilisable in this way:—

Ferric chloride or bromide.
Ceric chloride or bromide.

(3) Metallic chlorides or bromides which act similarly to those just mentioned, but give rise to insoluble compounds of a lower degree of oxidation which enter into the composition of the image. The following substances behave in this way:—

Mercuric chloride and bromide.
Cuprie chloride and bromide.
Potass chloro-chromate.

(4) Mixtures of free hydrochloric or hydrobromic acid (or of a chloride or bromide in admixture with sulphuric acid) and an oxidising agent which, in presence of the silver image, liberate chlorine or bromine, which exerts its chlorising or bromising action on the silver image. These conditions are fulfilled when using the following oxidising agents:—

Potass bichromate, chromic acid.
Potass permanganate (followed by bisulphite)
Ammonium persulphate, potassium ferricyanide.

(5) Mixtures which directly liberate chlorine or bromine in presence of a chloride or bromide and of the silver image, but without addition of acid.

Potassium permanganate.
Potassium ferricyanide.
Ammonium persulphate.

All the foregoing are mineral substances; hitherto organic compounds capable of liberating chlorine or bromine from hydrochloric or hydrobromic acid in presence of the silver image, and thus permitting the conversion of this image into chloride or bromide, as in the case of the mineral oxidising agents, have not been pointed out.[1]

We have observed, however, that this reaction can take place with benzoquinone and its sulphonic derivative, the peculiar use of which for various photographic reactions we have already noticed. It is sufficient to add to its solution in water a little hydrochloric or hydrobromic acid or a mixture of sulphuric acid and a chloride or bromide.

The reaction which takes place can be represented by one or other of the following equations:—

$$C_6H_4\begin{matrix}=O\\=O\end{matrix} + 2HCl + Ag_2 = C_6H_4\begin{matrix}OH\\OH\end{matrix} + 2AgCl$$

(or HBr) (or AgBr)

$$C_6H_4\begin{matrix}=O\\=O\end{matrix} + 2N\ Cl + H_2SO_4 + Ag_2 = C_6H_4\begin{matrix}OH\\OH\end{matrix} + 2AgCl + Na_2SO_4$$

The proportions of the reacting substances which correspond with these equations, on the basis of 5 gms. of quinone (which dissolves in the cold in 1,000 c.c.s. of water), are as follows:—

(*a*) For conversion into chloride—

Quinone	5 gms.
Sodium chloride	6 ,,
Sulphuric acid	3 c.c.s.
Water	1,000 ,,

(*b*) For conversion into bromide[2]—

Quinone	5 gms.
Potass bromide	11 ,,
Sulphuric acid	3 c.c.s.
Water	1,000 ,,

These solutions allow of the silver image on either a plate or paper print being rapidly converted into chloride or bromide without staining of the gelatine. The process of conversion into bromide is more rapid than that into chloride. The images which have been treated in this way can be subjected to the following series of processes such as are commonly employed in respect to negatives or prints which have been converted to chloride or bromide:—

(1) Reduction by a developer. This reduction restores the silver in the metallic state, and modifies the original colour of the image without producing any appreciable intensification. On the other hand, conversion of the chloride or

1. MM. Lumière and Seyewetz themselves have shown the utility of a mixture of quinone or quinone sulphonate in admixture with bromide for intensification and colour toning. See "B.J.," Dec. 16, 1910, p. 949.—Eds.
2. The alkaline chloride or bromide and the sulphuric acid can be replaced by the corresponding quantity of hydrochloric or hydrobromic acid.

bromide image into silver sulphide by means of alkaline sulphide produces a certain amount of intensification.

(2) Reduction of the dense parts of the image by chemical reduction of the chloride or bromide of silver by a developer whilst this process is stopped before it has affected the heaviest deposits. The image is then treated with hypo, which dissolves the silver chloride or bromide not acted upon by the developer.

(3) Toning of positive prints by re-development or by conversion into sulphide.

It will thus be seen that benzo-quinone or its sulphonic derivative in the presence of hydrochloric or hydrobromic acid (or of substances which generate one or other of these acids) constitutes a convenient and new process for the conversion of the silver image into one which consists simply of silver chloride or silver bromide without the addition of any other substance.

A. AND L. LUMIÈRE.
A. SEYEWETZ.

THE NEW SECRETARY OF THE R.P.S.

SINCE there are very many members of the Royal Photographic Society who have not the opportunity or occasion to visit the Society's house, the portrait of the newly-elected secretary, Mr. H. H. Blacklock, which we reproduce, will no doubt be of interest, particularly to members outside the London area. Mr. Blacklock is of the excellent age of 35, a time of life at which many of the

illusions of youth have been rejected, and when the prospect of a spell of years of full mental and physical activity lies in the future. It would be difficult for anybody to draw up a schedule of the qualifications to be desired in a secretary for the R.P.S., but it seems to us that Mr. Blacklock's career up to the present time suggests that his experience fulfils the chief requirements at Russell Square. After filling a post for some years in an insurance office in his native city of Bristol, he was for a considerable period secretary to the British Chamber of Commerce for Italy at Genoa. On his return to England, journalism occupied him for a while, and during recent years he has been secretary of the Royal Society of Painters in Water Colours, and of the Royal Society of Painter-Etchers and Engravers. Whilst holding these positions he was, during 1916, 1917, and 1918, secretary for the exhibition of the London Salon of Photography. Commercial manager, journalist, and exhibition organiser appear thus to be fortunately blended in him, and these qualifications, combined with an attractive personality, should make him an efficient and successful promoter of the progress of the Royal Photographic Society.

AN ELLIOTT AND FRY FESTIVITY.—On December 30 at the Portman Rooms, Baker Street, W., the staff of Messrs. Elliott & Fry Ltd., held their annual gathering, which took the form of a most successful dance and whist drive. There were about 120 present.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Smith's Reducer.

DURING the war, when the price of all chemicals, especially those depending upon the base, potassium, went up almost sky high, Mr. W. J. Smith, of the Bolt Court School, published a formula for a reducing solution as a substitute for the iodine and cyanide reducer so necessary for the production of screen negatives from which the half-tone blocks are printed from on copper. Directly after publication I tried the formula, and at once recognised that it was in every way superior to the old iodine-cyanide preparation, giving cleaner results, and being far more controllable.

Although published during a time of stress, the formula seems but little known, a fact brought to my notice rather forcibly during a lecture I gave before the R.P.S. This reducer can be made up in bulk, and always be ready for use, not made up at the last moment, and be either too weak or too strong.

The formula itself is quite simple, and is made up in two solutions :—

A.—Copper sulphate	... ...	1 oz.
Common salt	... ...	1 oz.
Water	... ...	25 ozs.

When dissolved add sufficient liquor ammonia to re-dissolve the whitish precipitate first formed. The result will be a clear solution of ultramarine colour.

B.—Hypo	... ...	5 ozs.
Water	... ...	25 ozs

For use mix in equal parts, and dilute as may be found desirable.—W. T. WILKINSON.

Vignetting.

WHEN a tricky vignette has to be printed in a frame on any "development" paper it is often difficult to see just what the vignetting card is doing, especially with dense negatives. In such cases good results may be obtained by replacing the wooden back of the printing frame by a sheet of clear glass—an old plate-glass does well if cleaned—the springs of the frame being bent slightly, if required, to hold all firm. The whole is then held up to the printing light, frame in one hand, vignetting card in the other, when the amount of paper exposed by the card is viewed from behind through glass, paper and negative, and the size and softness of the vignette can be judged to a nicety.

It sometimes happens that a print from part of a negative is required on a white background. This is easily obtained by placing the bromide or gaslight paper in position on the negative in printing-box or frame and lightly pencilling the required outline on the back of the paper by aid of the transmitted safe-light. Exposure is now made without moving the paper, which is subsequently soaked for a few minutes in clear water and laid, face up, on a sheet of clear glass. This is then held up against any safe-light, when the pencilling will show up clearly enough to allow of the required parts being developed with a suitably sized brush. It is well to have a basin of water handy for swilling in case of the developer running where not required.—A. U.

A Spotting "Tip."

SPOTTING on glossy paper which has to be glazed is always a bit of a nuisance, but excellent results can be obtained by using waterproof drawing ink—for instance, "Mandarin." After spotting, the ink is allowed to become quite dry, when the print may be soaked and squeegeed on a ferrotype in the usual way. When the print is stripped the spotting will be perfectly imperceptible. Titles and so forth can be written or printed and glazed in the same way. Waterproof ink can also be used to block out a background when an odd print or so of statuary or anything of that sort on a solid black or coloured ground is required. In this case the print needs mounting carefully, as the ink, after glazing, is fairly brittle.—A. U.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, December 20 to 24 :—

PLATE HOLDERS. No. 36,269. Plate holders for cameras. H. R. Eason

PHOTOGRAPHY.—35,988. Photography. F. W. Kent.

CAMERAS.—No. 36,083. Photographic film cameras. K. Koehl

TRIPODS.—No. 35,873. Tripod mountings for photographic cameras. B. L. Oldfield.

X-RAY PLATES.—No. 36,112. X ray plates. A. L. Landau and L. A. Levy.

CINEMATOGRAPHY.—No. 35,695. Cinematograph projectors. F. M. Beesley.

CINEMATOGRAPHY.—No. 35,696. Cinematograph film-feed mechanism. F. M. Beesley.

CINEMATOGRAPHY.—No. 35,859. Cinematograph apparatus. W. van den Broeck.

CINEMATOGRAPHY.—No. 36,072. Cinematographic projecting-apparatus. H. Brown and E. E. Cadett.

CINEMATOGRAPHY.—No. 36,018. Cinematograph projectors. F. Stock.

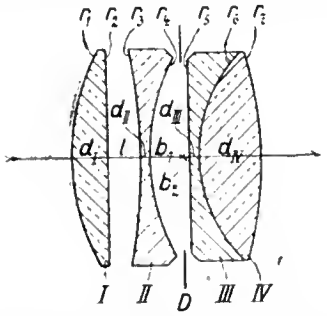
COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FOUR-LENS ANASTIGMAT OBJECTIVES.—No. 146,213 (November 14, 1917). The invention relates to photographic lenses consisting of four glasses, two of which are joined in a collective cemented surface, while between the other two, which are disposed at one and the same side of the cemented lenses, and of which the outer one is a collective lens and the inner one a dispersive lens, there is an air space, and they form a pair of facing surfaces having a negative power. The object of the invention is to secure in addition to the chromatic and a good astigmatic correction, as just attainable in the present type of objectives, which is described, for instance, in the Patent Specification 13,061 of 1902, a still better spherical correction than hitherto obtained in this type.

According to the invention such improvement is obtained in an extraordinary degree by so choosing the radius of curvature of the cemented surface that it amounts at least to one-tenth, and at the most to one-half of the focal length of the objective,



and by additionally so choosing the kinds of glass for the two cemented lenses, that the difference between their refractive indices for sodium light lies between 0.05 and 0.02.

In the known objectives of the present type, besides an anastigmatic flatness of the field extending over a comparatively large angle, a spherical correction had been attained so far that rays of a certain finite height of incidence, generally the rays impinging upon the marginal zone and the axial ray possessed a common axial point of intersection, hence the same intersectional distance. However, all other rays impinging between these distinguished rays showed a spherical aberration, which from the axis onward ascended from zero up to a maximum value and from there up to the distinguished zone again descended to zero. By choosing the radius of curvature of the cemented surface and the kinds of glass for the two cemented lenses in accordance with the present invention, the ascent of the spherical aberrations may be counteracted, and a more favourable course of the aberrations extending over the whole aperture of the objective be attained. When, in the customary manner, the differences between the intersectional distances of rays of any height of incidence and the intersectional distance of the axial ray are designated as abscissæ and the heights of incidence as ordinates, it is possible to ensure that the curved line which connects the corresponding points for rays of a different height of incidence—and which always must (from the axial point of intersection onward after initially turning aside from the axis of ordinates, in its further course within the area corresponding to the aperture of the objective) again approach this axis, whereby in a given case it intersects this axis within the aperture-area—contacts in the point of intersection of the axes with the axis of ordinates in a higher order than hitherto, or that the curve gets two turning-points. For both kinds of course of the curve the highest amount of the spherical aberration existing within the entire aperture-area may be kept in substantially lower bounds than hitherto. In most cases it will also prove possible to have the curve intersect the axis of ordinates within the aperture-area of the objective, which will allow of the objectives corresponding to the invention to be designated as spherically corrected in the usual sense. When the curve of aberration, as is the case in the last named course, possesses two turning points, then as a rule two such points of intersection will be obtained. However, sometimes the kinds of course of the curve as described will not permit the curve to intersect the axis of ordinates within the aperture-area, *i.e.*, it will be impossible to obtain a spherical correction in the usual sense. But even in such cases in objectives corresponding to the invention the maximum amount of the aberration may still be kept within substantially lower bounds than hitherto possible in objectives of the present type. Moreover, in objectives corresponding to the invention the difference between the refractive indices of the two cemented lenses is great enough for maintaining characteristic effect, which the cemented surface produces on the correction of oblique pencils.

The drawing shows a constructional example of an objective corresponding to the invention in axial section.

In this example the two lenses with an air space between, marked I. and II., are separated from two cemented lenses, marked III. and IV., by a diaphragm D, the outer lenses of the two cemented lenses being a collective one and the inner lens a dispersive one. This objective is to be introduced into the path of the rays in such a manner that the single collective lens faces the object. The objective is intended for use for a maximum relative aperture of I : 5.5, and the anastigmatic flatness of the field extends to about 60 deg. In the drawing and in the table r_1, r_2 . . . signify the radii of curvature, d_I, d_{II} . . . the axial thickness of the lenses, b_1 and b_2 the distances from the diaphragm D to the adjacent lens vertices, and l the central thickness of the air-lens between the glass-lenses I. and II. The numerical values of these magnitudes are proportional numbers applying to the focal length of the objective of 100 units. The kinds of glass used are characterised by the refractive index n_D relating to sodium light, and by the reciprocal power of dispersion γ. The data of construction are as follows :

Radii of curvature :		Thickness and distances :	
r_1	$= +20.09$	d_I	$= 3.24$
r_2	$= +\infty$	l	$= 2.96$
r_3	$= -53.71$	d_{II}	$= 0.82$
r_4	$= +18.89$	b_1	$= 2.96$
r_5	$= -1136.75$	b_2	$= 0.46$
r_6	$= +13.31$	d_{III}	$= 0.82$
r_7	$= -33.72$	d_{IV}	$= 5.66$

Kinds of Glass :

	I	II	III	IV
n_D	1.53227	1.56660	1.53212	1.57830
γ	58.3	42.9	51.3	54.0

Carl Zeiss, Jena, Germany.

New Materials.

CAKE-FORM PHOTOPAKE.—The Vanguard Manufacturing Company, Maidenhead, have issued their well-known blocking-out mixture in semi-solid form, contained in flat metal receptacles. Apart from the convenience, especially to the small user, of having the preparation in more concentrated form, dealers no doubt will appreciate the distribution of this well-known product in unbreakable receptacles. "Photopake," in its original liquid form, has been before the photographic public for over twenty years, and may be said to have established itself as the standard article for the spotting and blocking-out of negatives. The new issue is not made for the purpose of displacing the existing kind, but for supplying the material in a form which perhaps the amateur worker will prefer to have. It is issued in two sizes, price 1s. 6d. and 2s. 6d. Orders should specify "cake" by way of distinction from the liquid variety.

Commercial & Legal Intelligence.

LEGAL NOTICES.—The partnership between Eric Vine Colyer and Ernest George Southey, carrying on business as draughtsmen and photo-printers, etc., at 39, Cursitor Street, Chancery Lane, W.C., under the style of Colyer and Southey, has been dissolved by mutual consent. All debts due to and owing by the late firm will be received and paid by E. G. Southey, who will continue to carry on the business.

NEW COMPANIES

PEARSON AND DENHAM (PHOTO), LTD.—This private company was registered on December 24, with a capital of £12,000 in £1 shares (7,000 cum. participating pref.). Objects: To acquire the business carried on at Bond Street, Leeds, as Pearson and Denham, to adopt an agreement with A. A. Pearson and W. Denham, and to carry on the business of makers of and dealers in photographic apparatus and requisites, photographers, printers, etc. The subscribers (each with one pref. share) are: A. A. Pearson (chairman), Fairbourne, Fearnville View, Roundhay, Leeds, photographic dealer; W. Denham, 3, St. Michael's Crescent, Headingley, Leeds, photographic dealer. The permanent directors are: A. A. Pearson, W. Denham, and G. Denham. Remuneration of chairman, £250 per annum; of ordinary directors, £25 per annum. Registered office: 21, New Station Street, Leeds.

FORTHCOMING EXHIBITIONS

December 24, 1920, to January 8, 1921.—Scottish Photographic Circle. Secretary, W. S. Crocket, 10, Parkgrove Terrace, Tollcross, Glasgow.

January 6 to 8.—North Middlesex Photographic Society. Hon. Secretary, E. C. Ridge, 88, Ambler Road, Finsbury Park, N.4.

January 22 to February 5.—Northern Photographic Exhibition. Latest date for entries, January 15. Particulars from the Hon. Secretary, Liverpool Amateur Photographic Association, 9, Eberle Street, Liverpool.

February 14 to 19.—Leicester and Leicestershire Photographic Society. Latest date for entries, February 5. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

February 19 to March 12.—Scottish Salon, Dundee. Latest date for entries, January 31. Particulars from the Hon. Secretary, James Slater, Rosemount, Camphill Road, Broughty Ferry.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Latest date for entries, March 17. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, JANUARY 10.

Bradford Phot. Soc. "Tips and Dodges About Apparatus."
Cripplegate Phot. Soc. "Westminster Abbey." H. W. Fincham.
Dewsbury Photographic Society. Annual General Meeting.
Dundee and East of Scotland Phot. Soc. "Copying." M. G. Rae.
South London Phot. Soc. "More Gems of Architecture." E. R. Bull.
Walthamstow and District Photographic Society. "Toning Prints." E. Willcocks.
Welfare Camera Club, Linthouse. Annual General Meeting.
Willesden Photographic Society. Lantern Slide Competition.

TUESDAY, JANUARY 11.

Royal Photographic Society. (1) "Some New Directions for Photographic Research." Julius Rheinberg, F.R.P.S., F.R.M.S. (2) "A Monochromatic Illuminator of Special Design." F. C. Toy, M.Sc.
Bournemouth C.C. "Bromoil." Mr. Burroughs.

Photomonographic Society. "An Introduction to the Study of the Hydroida." E. Cuzner.
Rochdale Phot. Soc. "Colour Photography." H. Dawson.
Woodford Phot. Soc. "Ramble Round Dorking." A. H. Redman.

THURSDAY, JANUARY 13.

Brighouse Photographic Society. "Here and There with a Camera in the North Riding." E. S. Maples.
Camera Club, The. Criticism of Members' Exhibition, by Mr. F. C. Tilney.
Dundee and East of Scotland Photographic Society. "The Charm of Venice." Rev. J. R. Forgan.
Everton and District Phot. Soc. "Jersey." W. A. Mackie.
Hammersmith (Hampshire House) Photographic Society. "The Pyrenees." M. O. Dell.
Hull Photographic Society. Y.P.U. Slides.
North Middlesex Photographic Society. "Toning and Staining Bromides and Slides." E. C. Ridge.

FRIDAY, JANUARY 14.

Bedford C.C. "Elementary Photography of Animals and Birds."
Dennistoun Amateur Photographic Association. Bromide Enlarging.

ROYAL PHOTOGRAPHIC SOCIETY

Meeting held Tuesday, January 4, the president, Dr. C. H. Bothman, in the chair.

Mr. N. E. Luboshez delivered a lecture on portraiture by artificial light, in special reference to the results which he obtained when giving a demonstration before the Society some months ago. He showed a large series of lantern slides, many of them prepared from the negatives taken on that occasion; others of subjects which he had photographed in various parts of Europe, and still others from reproductions of portraits by Rembrandt, Hals, and other masters.

Inasmuch as a lecture by Mr. Luboshez, because of its exuberant flow of language and its spasmodic deviations into side issues, almost defies transliteration in cold print, it must suffice to say that the present discourse had for its chief theme the preservation of unity of lighting in photographic portraiture. Mr. Luboshez laid stress on this again and again in showing portraits which he had made by every known source of illumination, arc light, half-watts, mercury-vapour, magnesium ribbon and daylight. Some of his comparative examples were exceedingly striking, in particular a series of portraits of Mr. J. C. Warburg, of whose grave and philosophical countenance a strikingly false rendering was produced by a species of "fancy" lighting; the obvious truth and dignity of portraits almost identical in pose, but with a unified lighting, was exceedingly striking. But Mr. Luboshez is a wizard,

who shows astonishingly clever and beautiful things, but finds it difficult to explain the *modus operandi*. However, wizardry, even if it is not explicit, can be highly stimulating: and no one could listen to Mr. Luboshez and see his examples without realising what an immense distance most photographers have still to go before they can claim a mastery of lighting the sitter for the photographic process. With Mr. Luboshez, who has sat at the feet of the old masters, the technique of lighting has become an instinct, and, moreover, has become inseparable from the development of the plate. Mr. Luboshez said that he developed his plates by the tank system, but it is inconceivable that, with his finely balanced sense of the gradations which a negative should exhibit, he is ever able to leave a plate to the blind operation of time development.

A short discussion followed, and a most cordial vote of thanks was accorded to Mr. Luboshez.

News and Notes.

Royal Photographic Society.—The following members have been admitted to the Fellowship:—Mr. E. A. Bierman, Capt. F. R. Logan, Rev. H. O. Fenton, Mr. Thomas A. Scotton, Mr. H. B. Goodwin, and Mr. Horace Jackson.

The Wellington Calendar for the present year is an exceedingly handsome art board bearing a charming photograph of a child's head and a tear-off calendar, which revives the quaint drawings which at one time were an attractive feature of Messrs. Wellington & Ward's advertisements. A copy of the calendar will be gladly sent to any *bona fide* professional photographer who has not yet received a copy on application to Messrs. Wellington & Ward at Elstree, Herts.

Anglo-German Debts.—British nationals, who have registered claims against German nationals in respect of pre-war debts, will shortly receive a notification from the Clearing Office that the last day for making the necessary statutory declaration in support of their claims is March 31, 1921. No claim in respect of pre-war debts will be admitted which is lodged after that date, unless the Controller of the Clearing Office is satisfied that the omission to lodge the declaration by the date mentioned arose from circumstances for which the creditor could not justly be held responsible.

Twenty-five Years of Motoring.—Our admirable contemporary, "The Autocar," has just issued a souvenir booklet, which marks the completion of twenty-five years of publication. The booklet contains a reproduction of what is evidently a photograph of King Edward VII. on his first motor drive in 1898 in a two-cylinder Daimler car, the mere outward shape of which tells us how rapid the development of motor vehicles has been. A host of personages in the motor industry testify with such unanimity to the valuable services which our contemporary has rendered, that it is almost superfluous for us, as regular readers of its pages, to add a tribute from the standpoint of the motoring public.

The Year's Patents.—Messrs. Rayner & Co., patent agents, of Chancery Lane, E.C., state in a letter to the Press that the past year shows the highest number of patent applications ever registered in the British office, the total being slightly over 36,600 against 32,853 in the next best year of 1919. While these figures prove the active interest taken in inventions, it must be remembered that there had been a great influx of foreign patents last year owing to the extension of time allowed by the Peace Treaty for the taking of English patents under the Convention; but an equal privilege is also allowed to British inventors in taking patents abroad. Unfortunately, this arrangement does not apply to U.S. America, which State has not yet signed the Treaty. British inventors, however, should know that they can still file patents in Germany up to January 10, and in France until March 31, for any inventions they patented here during the war period.

Annual Exhibition at Messrs. Wahltuch, Smith & Co., Ltd.—Messrs. Wahltuch, Smith's exhibition at 30, Chapel Street, Salford, Manchester, opened this year rather earlier than usual. An excellent assortment of furniture, accessories and materials were presented for the approval of photographic visitors. The principal item of the show is a new bevelling machine designed to cut circles and ovals either inside or out. With this machine the photograph to be bevelled is clamped to a movable board, and the knife is set by means of a gauge, which allows very rapid adjustment. In cutting, the knife itself is stationary, while the board carrying the photograph moves. An important point with this machine, as all who have experience of bevel cutting will appreciate, is the movable knife which can readily be sharpened, stropped, or replaced. This machine is certainly a useful innovation for those who study the art of photographic mounting.

Some very good designs in furniture are on view, a noticeable point about Messrs. Wahltuch, Smith's furniture being the fact that it is at once light, strong and durable. An improved set of children's Dutch furniture suggests many possibilities. The original white has been dropped in favour of dark oak upholstered, but the Dutch paintings are retained. The small chairs in the Dutch set are so built that they can be placed together in different ways so as to form two different sized settees and a *tête-à-tête* seat, while the different pieces are light and pretty. Two very comfortable types of cane seat are shown, and a notable high-backed chair specially designed for evening dress portraiture. This piece suggests dignity at the very first glance. A new model of settee is being made with and without arms, and some very neat oak tables with antique polish are on view. It is noticeable that prices in these lines are in many cases reduced.

As might be expected a very comprehensive set of backgrounds in grey and light sepia is on view. There are backgrounds here to suit every kind and style of portraiture, and almost every type of sitter. A point about all the firm's backgrounds is that they are the sole work of the firm's artist, and any desired modification in any design is readily undertaken to suit individual requirements, while purchasers' own designs are painted to order. The grounds on show are executed in greys and sepias.

A new camera stand combines lightness, strength and rapid adjustability in a large degree; it is provided with the usual raising, lowering, tilting motions, and these are all operated by slight pressure, while the base of the stand is so shaped as to provide receptacles for slides. This stand is marked at the moderate figure of £6 6s.

The Dallon washer is an enamelled iron structure on the cascade principle, and should wash prints in a clean and efficient manner; it is made in four standard sizes, and can be made in any other size to fit special requirements. An adjustable hanging dark-room lamp is so made that it can be hung at any desired angle without any trouble, and its inclination altered at a moment's notice. A simple red lamp to fit an ordinary electric light also seems to be useful. A new type of hypo-alum toner is constructed of white enamelled iron, and made large enough to hold anything up to 20 x 24. The well-known "Anysize" strip printer has been simplified and improved, and printing on this machine of anything from 1½ ins. to 8½ ins. wide, solid, masked, or vignetted, should be simple, rapid and sure. A new machine, the "All-work," is shortly to appear.

Among the many sundries shown are specimens of the Pytram specialties, including models for use with child studies, and the pieces of ornamental furniture in copper. Among animal toys for the studio a little dog forces itself upon the attention of visitors by his loud, insistent barking. This accessory, which can be held in the palm of the hand, is not meant for photographing, though the face is most real, but for attracting the attention and interest of little people, and it should prove a godsend to many harassed operators.

A novel piece of drying apparatus is a line which winds out of a small metal fixture, and can be stretched across the work-room either single or double. When not in use the line is drawn back into the fixture where it does not intrude itself on one's view.

In materials, Messrs. Wahltuch, Smith & Co., Ltd., are putting forward their gaslight papers for studio use, and the many specimens shown emphasise the argument that to work in comfort does not mean a poorer quality of output, but just the reverse. Some specimens on slow, soft paper in particular show results that could hardly be equalled, and certainly not excelled on any bromide paper. It certainly appears that slow papers which can be worked in plenty of light are going to oust popular bromide from the position it has so long held.

RAILWAY PHOTOGRAPHERS.

To the Editors.

Gentlemen,—I note a letter in your last issue signed by Mr. I. Tennant Woods, in which a reference is made to my father and myself. It would be most interesting to learn who was the first railway photographer.

My father commenced taking photographs for the Midland Railway about the year 1877, and held the position until his death in 1894. I joined him at the beginning of 1883, and succeeded to the post, and have held it ever since.

The 26 in. x 21 in. camera, which was fitted with a 20-in. focus Ross portable symmetrical lens, was first used in the early 'eighties, and was the one employed in photographing the first Convention group in 1886; it is still in use.

Previous to 1881 wet plates were used of 15 in. x 12 in. size, and it was no small matter, I can assure you, using these up and down the line (I have recollections of going several trips as a boy) photographing bridges, &c., for the engineer.

I thank Mr. Woods for his kindly remarks.—Yours faithfully,

T. A. Scotton, F.R.P.S.

PAPER NEGATIVES WITHOUT GRAIN.

To the Editors.

Gentlemen,—Referring to the article under the above title in the current issue of the "Amateur Photographer" of December 22, I am sending a few specimens with notes on my experience.

Some two or three years ago I had occasion to enlarge some very small photographs from paper negatives about ½-in. square. They were made by placing a piece of glossy P.O.P. in contact with the positive prints, same size, and printing by daylight in an ordinary printing frame many years ago.

The usual procedure of making contact prints and then enlarged negatives on glass did not prove the least satisfactory, and the idea occurred to me to make enlarged positive prints direct from the small negatives in the same way as I would copy any ordinary photograph in making a copy negative on a glass plate. This I found to be a great improvement. I saw at once great possibilities in this process and made two exposures on ordinary bromide postcards of one of my assistants, which proved quite satisfactory. Being then too busy with war work to follow it up, I did nothing further in the matter until the spring of this year.

I am sending you herewith some prints and the negatives on bromide paper made at that time in May of this year; also a cutting from the "Greenock Telegraph" of June 3, in which you will see a notice of the same in photographic column. No doubt better results could be got, as these are practically a first attempt. Bromide paper is too slow for portrait work in the studio, and the latitude in exposure is not so great as with glass plates. I wrote to several large firms about supplying negative paper with rapid emulsion, but failed to interest them, and got no encouragement. However, as Mr. Stewart says, "this is not merely a theoretical proposition," and it is bound to come, even if it should have to come from Germany.

Platino matt paper, such as Mr. Stewart has used, is about the worst he could use. I am inclined to favour Wellington carbon surface. Glossy is good enough for view work, but the carbon surface is better for studio portraits, and can be retouched. This I do with a sable as in spotting prints.

I do not mount the negatives on cardboard, as Mr. Stewart suggests. I get much better results by squeegeeing it on to a piece of glass, and all the better to "copy" or "print" while wet. This is the speediest way to get a print for urgent purposes, as you need not fix the negative more than a minute or so, after which it can be put back into the hypo. again.

The unmounted negative, if dried, can be put into a printing frame with a border paper negative in front, and with the centre cut out showing the print through; a print with a border can then be got with one "impression." In fact, there is no end to the variety of ways it can be used, such as in sketch work, etc., impossible with plates.

As to cost, my first whole-plate negative was made at a cost of one penny, against one shilling and twopence for glass plate, plus developer.

The process seems to be very adaptable for copying engravings, as you will see from the enclosed print. In fact, I have done worse work with a glass plate negative. When I can get a supply of suitable paper coated with rapid plate emulsion I am sure my plate bill will not be so high. Many amateurs who only possess a small snapshot camera will not be able to use this process unless they have an enlarger, but I am sure many professionals may find it of great advantage.

The whole-plate portrait of a lady enclosed was made with an 8-in. T. T. and H. Cooke anastigmat at *f*/6, six seconds exposure, and is quite passable for a postcard lens. The reason was to get speed.—Yours truly,

Norman Hunter.

The Studio, Port Glasgow.

December 27, 1920.

[Our correspondent's results are very interesting. Considering the very smooth surface (semi-glossy) of the paper on which the prints are made, grain is little in evidence, particularly in one example. The practicability of negative paper turns in the end on the retouching question. At present we do not think it can be said to be fully demonstrated, but Mr. Hunter has certainly described methods which contribute to a solution of the problem.—Eds. "B.J."]

THE POSITION OF PHOTOGRAPHIC SOCIETIES.

To the Editors.

Gentlemen,—A feeling of fairness compels me to politely disclaim "Fuller Hope's" kindly reference to myself in his interesting letter of last week, which pictures a gloomy state of affairs. It is true that a band of willing workers and cheerful souls contribute in large measure to the "aliveness" of the Croydon Camera Club, but all admit its popular and hard-working secretary, Mr. Sellors, stands easily first, with the president, Mr. Keane, a good second. My subsidiary and distressing position involves little labour, but does subject me to the secretary's careful attention when anything happens to go wrong, or not exactly right. Those who know him will comprehend what this implies.

It is to be hoped that secretaries of societies will give their views and express their opinions on the letter of "Fuller Hope." Permit me formally to subscribe myself,—Yours very respectfully,

The "Office Boy."

WARMING THE STUDIO.

To the Editors.

Gentlemen,—I was very interested in reading your article on "Forms of Heating Studios and Workrooms" in the "B.J." of December 24 last. It has been my experience to find many studios insufficiently heated, and in many cases without heating apparatus of any kind. This must be very detrimental to both the operator and sitter, especially where ladies and children are concerned, and most of your readers will admit the importance of having a warm and cheerful atmosphere in the studio.

It appears to me that an ordinary coal fire, gas, or anthracite stove, is quite unsuitable for a studio on account of the dust, dirt and fumes, also the unequal heat they give. I have recently come across a new invention, which struck me as being ideal, and which, I think, surpasses any method of heating and ventilating yet obtained, and should appeal especially to the photographic trade. This invention is known as the "Ventihota," of Argyll Street, Oxford Circus, W., and directly I saw the apparatus working I came to the conclusion it was the most suitable for photographic studios and workrooms. The apparatus is artistic and neat in appearance, and will keep a room or studio at a comfortable and even temperature at an appropriate cost of 6d. for twenty-four hours.

Fresh air is automatically drawn in, warmed and distributed, and any bad air expelled. Many of your readers must have experienced the difficulty of clearing the studio of fog, even after it has cleared outside, but by the use of this invention it would be replaced in a very few minutes by warm, pure air, which flows in at the rate of 3,000 cubic feet per hour. The "Ventiheta" is adapted for either gas or electric current.—I am, yours faithfully.

FREDERICK E. JONES.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. G.—Certainly, there is no objection to doing as you say; it is the usual course unless arrangements are made for exclusive use by one periodical.

W. C. B.—The "Agenda Lumière" is only published in French. Parts of it are however obtainable in English in the literature published by Mr. T. K. Grant, 89, Great Russell Street, Bloomsbury, London, W.C.1.

G. P.—No licence is required for carrying on the business of developing and printing amateurs' films, except that if you do not trade under your own name you require to be registered with the Registrar of Business Names, 39, Russell Square, London, W.C.1, at a cost of 5s.

M. L.—You would of course study the wishes of your customers, as much depends upon the method of working up. In the ordinary way we should recommend such a paper as Ilford rough, which has only a moderate grain and which takes water or oil colour and chalk equally well.

B. T.—(1) The only two lamps which we can connect with your question are the "Pointolite," of the Ediswan Electric Co., Ponder's End, Middlesex, and the focus type of the "Osram," made by the General Electric Co., Magnet House, Kingsway, London, W.C.2, in a series of candle powers. (2) As regards formulæ for tank developer you cannot do better for small quantities than use any ordinary pyro-soda, diluted with 3 or 4 times its bulk of water.

P. S.—Reducing the depth of sulphide-toned bromides is rather a tricky business, but most toned bromides will be appreciably reduced in depth by immersion in cyanide solution. We do not recall the formula you quote, but we should say it would work as well as any other. But at the same time we don't think that any formula for the reduction of sulphide-toned prints is really perfectly satisfactory, since there is always the liability of both the colour and the gradation of the print suffering.

M. A.—From what you tell us it looks as though you cannot do with a lens of greater focal length than 7 ins. for your full length postcard work. We suppose, although you do not say so, that the Homocentric and the R.R. do not get all the figure on the plate, but we think a 7-in. lens would just about do that. If that is so, then you really would require for good definition all over the postcard plate an anastigmat of, say, *f* 6 aperture. A portrait type of lens has not sufficient covering power, nor have most R.R.s. If you are not very particular as to speed there is no doubt you could easily choose a suitable lens from the list of one or other of the second-hand firms.

F. B.—We think there is nothing in pyro for the colder tones, rather the other way about. The odourless toners give a somewhat less yellow tone, but the thiomolybdate is not now on the market, and the only toner of this kind is that sold in the form of tabloids by Burroughs Wellcome. We think your best plan is to use either the Greenall method or the Bennett method. Of course the Bennett method has mercury in the bleacher, and to that extent is open to objection on the score of permanence, but we think the results are reasonably permanent when the after bath consists only of sulphide. With some papers a great improvement in tone in the way of avoiding yellowness is obtained simply by giving a preliminary bath of sulphide before carrying out the usual process.

G. K.—Without any doubt whatever flashlight has considerable disadvantages for studio portraiture. It is not so much the effect in the portrait of the sudden flash, since the photograph is taken before the effect of the flash has been felt. But there is the difficulty of making a series of exposures, due to the accumulation of smoke and also to the sitter becoming nervous unless the flash is almost silent. The smoke nuisance can, of course, be perfectly obviated by burning the flash in a chamber with a draught pipe to the outside air, and providing a thoroughly good powder is used you can obtain suitable methods if ignition for fairly silent working, although this is a difficulty if you want to make certain that the flash goes off at a given instant. The best advice we can give you is to be advised as regards the design and equipment of an installation by a specialist in flashlight appliances. Mr. D. Charles, of 45, Beaufort Road, Kingston-on-Thames, is well qualified to supply outfit to any required specification.

F. H.—(1) No doubt development prints, bromide and gas-light, will come to no harm through the presence of even a fair proportion of mild acids, such as salicylic or boric, in the mountant, but it is just as well to avoid anything of an acid nature as a preservative, for the reason that any, even feeble, acid will give rise to stains if prints have not been as completely fixed as they ought to have been, whereas a neutral mountant would probably avoid development of such stains. We think pure carbolic acid is a suitable preservative, although it is not much used commercially. The best of all for your purpose probably is thymol, used in the proportion of, say, 2 or 3 grs. per oz. by weight of the mountant. (2) There is no difficulty whatever in securing exposures of one or two seconds by means of electric light, that is to say, the half-watt lamps. Dependent on the size and colour of the walls of the studio the total candle power requires to be from 3,000 to 6,000 best divided between lamps each of 1,000 c.p. For practical purposes of regular work such an installation, which is easily arranged, is immensely superior to any magnesium installation. We know French photographers have rather a liking for flashlight in the studio, but we imagine that arises, in many cases, from unavailability of electric current. In our opinion the electric light is very greatly a more satisfactory and commercial method.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3167. Vol. LXVIII. FRIDAY, JANUARY 14, 1921. Price Fourpence.

Contents.

SUMMARY.

We publish this week a contribution by Lt.-Col. H. S. L. Winterbotham, of the Ordnance Survey, in which is reviewed the development, before, during and after the war, of aerial photographic methods for the production of maps. Lt.-Col. Winterbotham proceeds to draw his conclusions from this experience, and sums up the present status, as regards accuracy and economy, of aerial processes of mapping. (P. 16.)

Mr. Alfred Watkins, in some notes on factorial development, expresses his dissent from some of the conclusions recently advanced by Dr. B. T. J. Glover, and emphasises items from his experience of measurement methods of development. (P. 15.)

Mr H. W. Bennett at the Croydon Camera Club gave revised formulæ for the toning of bromide prints to colours ranging from engraving black to sepia. (P 26.)

In a leading article we urge upon professional portrait photographers the advantages to each individually, as well as to the profession as a whole, of preparing work to be submitted for inclusion in the exhibition of professional portraiture to be held in April next in connection with the forthcoming Congress. (P. 14.)

The very ingenious process of Mr. Elwin Neame for the photographing of a sitter (in the studio) against any natural background is described in the patent specification recently issued. (P. 21.)

A background possessing perspective space may contribute to composition of a portrait in a way which the customary flat surface cannot. (P. 14.)

A contributor to "Assistants' Notes" gives practical hints on photographing blue prints. (P 20.)

The Council of the Royal Photographic Society have awarded the Progress Medal to Mr. F. F. Renwick for his researches into the chemistry and physics of photography. (P. 25.)

A medal, and premium of 800 dollars, have been awarded to Dr Mees in accordance with an ancient American endowment. (P. 13.)

At the Royal Photographic Society on Tuesday evening last a demonstration was given of the process of development in full light by means of a desensitiser which has been worked out by Dr. Luppo-Cramer. (P. 25.)

The Manchester Amateur Photographic Society is raising its subscription from 7s. 6d. to one guinea, in order to meet the greatly increased costs of maintaining a full service for its members. (P. 23.)

The use of liquid Indian ink, in a greater or lesser state of dilution, forms a ready method of spotting bromide prints. (P. 14.)

Dewing of the lens through taking a small camera from the warmth of the pocket into a cold atmosphere may be a cause of veiled negatives. (P. 14.)

To-morrow (Saturday) is the last day for the receipt of exhibits for the Northern Photographic Exhibition which opens on January 22. (P. 13.)

EX CATHEDRA.

The Northern. To-morrow (Saturday) is the last day for the receipt of entries for the forthcoming Northern photographic exhibition at Liverpool. Those who may have delayed delivery of their intending exhibits until now should note that prints should be consigned to the Walker Art Gallery, Liverpool, but glass transparencies to the Liverpool Amateur Photographic Association, 9, Eberle Street, Liverpool. We hear that the exhibition, which opens on Saturday, the 22nd inst., is assured of being a great success, a success upon the scale of the shows which were held in the years before the war. Liverpool is fortunate in obtaining such an excellent place for the exhibition as the Walker Art Gallery, where conditions for the proper display of pictures are in many respects ideal. The organisers, and particularly the honorary secretary of the exhibition, Mr. Geoffrey E. Peachey, have left no stone unturned to bring together a great collection, representative not only of pictorial photography, but of the work of photographers in other fields, such as colour photography, nature study and scientific applications. Too wide an announcement of the period during which the exhibition remains open cannot be made: namely, from January 22 to February 5.

* * *

A Medal for Dr. Mees. We see it recorded in the United States Press that a John Scott Medal and premium (of 800 dollars) have been awarded by the Directors of City Trusts of the City of Philadelphia to Dr. C. E. Kenneth Mees for special researches on the structure of photographic images. The award has been made from an ancient bequest of John Scott, an Edinburgh chemist, who in the year 1816 established a fund from the interest on which distributions were to be made to "ingenious men and women who make useful inventions." By an extension of the terms of the endowment it was decided a year or two ago that the award and grant might be made to the author of any invention which, in the opinion of the trustees, might add to the "comfort, welfare and happiness of mankind." The researches carried out by Dr Mees and his colleagues in respect to which the award has now been made include the constitution of light-sensitive silver compounds, the sharpness of developed images, rendering of fine detail in photographs and "graininess" of the photographic image. The cynical may perhaps be prompted to inquire which of these, add directly to the comfort, welfare or happiness of mankind, but that would be to take a short-sighted and superficial view; for these questions, as our readers know, form part of the fundamental structure of photography, and any researches which contribute to their better understanding enlarge the field of photography as a whole and facilitate its usefulness in the world's work and play.

For Pocket Camera Users. Those photographers who use small pocket cameras should at this season of the year be on their guard against a defect that sometimes appears in negatives that strongly resembles light fog; in fact, we have known it mistaken for this. We refer to the condensation of moisture upon the front glasses of the lens when the latter is first exposed to a cold outside atmosphere after being carried for some time in the owner's pocket. Only the other day we were consulted as to some very foggy-looking negatives taken with a C.D.V. pocket camera. The origin of these was subsequently traced to the cause we have mentioned. It is well at this time of year prior to making an exposure to examine the lens carefully to see if it is quite free from cloudiness. If this latter exists it should be carefully removed with a fine handkerchief. This trouble generally manifests itself only after a great change in temperature such as from the user's pocket to the open air. Hence it is far more likely to be met with when using a small pocket camera than when a field outfit is carried in its case. After a lens has been exposed to the new conditions for a short time the moisture that may have collected will gradually vanish and its reappearance is unlikely, though it is well to be always on the watch for it.

* * *

Spotting Bromides. A method of taking out defects in bromide or gaslight prints, which may be commended to the amateur worker, is by means of a mapping pen and the "indian ink" sold in a liquid form for the use of draughtsmen. The ink, if too intense in colour, may be freely diluted with boiled or distilled water to the required degree, and in this way the tone of any part of the print may be easily matched. A good plan is to dilute one part of the ink with four parts; another, with eight or ten parts; and another, with sixteen parts of water. These three solutions are kept in small bottles, and the worker is then equipped for spotting a large number of prints and possesses a medium diluted to any required density. A fine mapping pen should be chosen, and an attempt made to take out the defect with one application of the pen. This is quite an easy matter; indeed, far more so than is the case when using a fine-pointed sable brush, unless the worker is practised. The method here advocated is of especial value for amateur workers, though, no doubt, some of our professional friends may find occasion for it. A point in its favour is that the ink is fixed and will not rub off; a decided advantage over water-colour and pencil spotting, especially upon glossy surface prints.

* * *

Perspective in the Background. It is somewhat curious to observe how seldom, in portrait photographs, the background is anything more than a flat surface. The choice of a background which shows the sitter in what is unmistakably part of a room is of such rare occurrence that it seems worth while to draw photographers' attention to the fact. In a recent issue of the "Professional Photographer" are a dozen reproductions of portraits from the P.P.A. exhibition of professional portraiture, and one of these stands out from the others by reason of the naturalistic effect obtained by the position of the sitter in the corner of a room. The predominance of the flat background is no doubt a heritage from the traditions of the portrait painters. While, no doubt, it eliminates difficulties which attach to a background which has perspective qualities, there is also no doubt that it presents opportunities for natural effects of lighting and of posing which are not afforded by the plain artificial ground. For example, it needs no demonstration to show that a balance of light and shade can almost always be obtained more readily in a background which is an angular space presented to the camera than in one which is a flat surface. The line where the two surfaces of the solid angle join may often be a feature of some difficulty, requiring to be softened, either at the time of making the exposure or afterwards on the negative.

THE INCENTIVE OF EXHIBITIONS.

Those of us who can recall the photographic exhibitions of the seventies and early eighties of the last century can realise the great change that has occurred in the style of work and the personnel of the exhibitors. In the early days the technique of photography had to be acquired by long study and practice, and, unfortunately, the qualities which made for success in this direction were not those which are popularly supposed to be wedded to the artistic temperament, so that the exhibited work was usually more conspicuous for mechanical perfection than for pictorial quality. Professional work then formed a much larger part of the show than it does at the present time, and it was considered as a point of honour by many firms to send representative exhibits year by year.

Time has altered all this. The introduction of bromide paper has placed the amateur with his Kodak almost on an equality with the professional, and the skilled manipulation which was needful to produce perfect large photographs on glossy paper has had to give way to pictorial interest. This, we think, no one will deny is all for good as regards the artistic status of photography, but it has destroyed the professional workers' interest in exhibitions generally, and this is certainly to be deplored by all who are interested in upholding the standard of professional photography either in portraiture or commercial work.

There is, however, one exhibition which is exclusively professional, viz., that held annually under the auspices of the P.P.A. at the Horticultural Hall, Westminster, in April. Here admirable examples of the current output of many of the best known workers are to be seen, and every photographer who can manage to visit it should not fail to do so, as he will there learn as he can in no other way, however closely his own pictures approach the high-water mark of modern photography. He should avoid the error of carping at work which he cannot equal, remembering that with many men there are many minds, and that a style of portraiture which does not appeal to his taste is not necessarily a bad one.

Good as is the moral effect of an exhibition upon the beholder, it is still better upon the exhibitor, particularly in the preparatory stage. It is a direct incentive to the production of the best work of which the individual is capable, and this is what the great majority of photographers need. In the ordinary way competition in quality is the last idea which enters their minds. Price-cutting, free sittings, window-dressing are all used in the hope of bringing business, but the actual quality of the photograph, provided it does not fall too low, is not considered.

Competition with the work of others is essential to progress in any art. No artist or craftsman can be assured that he is doing his best if he immures himself in his workshop and refuses to compare his work with that of his contemporaries, and undoubtedly exhibitions afford the readiest means for such comparison.

It is a great mistake to delay the preparation of exhibition specimens until within a week or two of the sending-in date. Every exhibition secretary can tell of exhibits

which have arrived just too late and were therefore rejected, and of others which have arrived in time but which were despatched with a feeling that better could have been done if a little more time were available. It is not too early to-day to prepare for an exhibition in April next, or in September next for that matter.

The exhibitor must be a good sportsman. If his work is not accepted by the judges or selecting committee, he must not begin to cry out about favouritism or incompetence, but try to find out in what respect it is lacking in attractiveness. At the same time the verdict need not altogether be regarded as final. Whistler was rejected by the Academy at one period, and his work was decried by such a popular critic as Ruskin; but time has justified the artist's methods, and his works are now properly appreciated. The remembrance of such happenings should prevent a feeling of discouragement in case of rejection, provided that there is a sufficiently firm conviction that one's work deserves a better fate.

We have referred more particularly to the Congress Exhibition because the professional photographer will here find himself upon more familiar ground than at the two older shows, the R.P.S. and the Salon. These, however, must not be overlooked, nor must it be imagined that only freak pictures have a chance of acceptance. The essential requirements for these exhibitions are pictorial interest and originality of treatment as well as good technique, and it is useless to send ordinary show-case work, no matter how good it may be. And, lastly, although most exhibitors prefer to submit large prints, size alone is not an important factor. An effective picture may be made on a whole plate or even smaller, and there is sometimes a delicate quality in a direct print which is lost in an enlargement.

NOTES ON FACTORIAL DEVELOPMENT.

THE valuable articles by Dr. B. T. J. Glover in the "British Journal of Photography" of December 17 and 24 last explore in detail and with accuracy the strong points and the weak points of factorial development, although, as I shall explain, I strongly disagree with one or more of his final deductions.

There is much need for careful work like Dr. Glover's, especially if it would take the form of information as to the factors to use for different developers, a point on which there is a great paucity of recent information. When I first devised and published the method (as an adjunct to systematic exposure by aid of actinometer) about 1894, I devoted two or three years of experimental work to giving all the information I could as to factors. But after a year or two I found that users began to regard me as one whose business it was to mix up and test their pet developers for them and to give them the result in reply to a post-card inquiry "thanking you in anticipation." And as I had no pecuniary interest in their use of the method, and had to devote the experimental energy which I and a trained assistant possessed to work on the speed of plates (which was and is a necessary adjunct to my business as a maker of exposure meters) I had to cease making any new trials for factors. It is a matter which really concerns the makers of developers or sellers of plates and papers. Messrs. Wratten (now of Messrs. Kodak) realised this as regards giving a factorial method for the development of lantern plates, but little else has been done. Dr. Glover's articles, unfortunately, only give one factor, that of 11 for bromide paper with the Eastman amidol formula. I do wish that makers would systematically, from their own trials, give factors for their own developer formulæ.

I thoroughly agree with Dr. Glover that factorial development has great advantages for development of bromide papers. I have before me a frame of six bromide prints from the same negative which I exhibited at the Royal Photographic Exhibition a few years after I discovered factorial development. It was, I know, well before 1904 when the first edition of my Manual was published, for I have always had in that book a page on factorial development for bromide papers. In this trial I took six different makers' papers, widely varying both in exposure speed and rate of development. I first ascertained the H. and D. speed of each paper (a troublesome matter), and having found by trial and error the right printing exposure for one paper behind the negative, I gave all the others exposures varying inversely with their relative speed. Then each was developed in a metol-quinol developer for four times the appearance of the image. The result was six prints practically identical. Other trials confirmed this.

Now for the point on which I disagree with Dr. Glover, both on theoretical grounds and on the results of long practical experience (my own and hundreds of others) in the method.

I think that he is fundamentally wrong in his final classification of classes of work for which factorial development is unsuitable.

In particular, I know that he is wrong in saying that it is unsuitable for development of plates exposed on outdoor subjects.

Let me first take the theoretical objection. It is also necessary to clear the way by pointing out that no available method of development is free from certain serious defects or contingencies which have to be guarded against in practice, and that to point out such defects is not sufficient to condemn the method. Otherwise, all methods have to be condemned. For example, if a plate maker makes an actual test of each batch, and gives accurate time and temperature development information for the emulsion as he sends it out, the user has still several very probable chances of going wrong which he must keep in mind. First, some emulsions alter in development speed within a month or two; secondly, all emulsions "go off" in development speed if kept long enough; thirdly, developers of the same formula vary in speed with different makes or purities of chemicals; fourthly, developers "go off" in energy if kept. Strangely enough, the factorial method overcomes in practice these peculiar weak points, although it has some of its own.

Factorial Weakness.

The weak points of factorial development are, firstly, that it gives a slightly varying time for two plates, one slightly over, the other slightly under exposed, whereas theoretically both should have the same time for development; secondly, that the observed time selected for the "time of appearance" varies a little in different subjects. Now these two objections have to be kept in mind and guarded against. But they are objections which come just as much into practice in the classes of work which Dr. Glover pronounces to be suitable (bromide printing, lantern plates, studio work, and copying by artificial light) for the factorial method as they do in those classes (outdoor subjects, enlarged negatives and positives) which he pronounces unsuitable.

I think that Dr. Glover has made a serious mistake in assuming that these classes of work done with artificial light tend to greater accuracy of exposure than those by fluctuating daylight. I know I can take any box of plates (when the speed has been tested) and with the aid of an exposure meter (an actual actonometer test) secure at first trial an exposure

within 50 per cent. of an ideal exposure, and this limit, provided there is a bit of sky or white object in the subject, does not lead to appreciable error in factorial development. On the other hand, if I am given a packet of bromide paper and an unknown negative to print from, my gaslight and distance may be "standardised" to my heart's content, but I know of no way of getting a correctly exposed bromide print except by "trial and error," that is, by exposing some trial slips. And if a negative of a different type is substituted, another trial must be made. In other words, a standard light does not ensure a standard exposure, and in practice the use of an actinometer exposure meter standardises outdoor exposures (together with indoor ones) more accurately than "trial and error" does for studio and artificial light work.

Dr. Glover (page 763) gives an example in which the "minimum correct exposure, calculated by meter of an open landscape" was 1-45th second, the time of appearance being 22 seconds. He exposed other plates for 1-22nd and 1-10th seconds, and got lessened times of appearance of 20 and 18 seconds. He appears (although he does not mention it) to assume that the man exposing the plate would deliberately give the wrong exposure of, say, 1-10 instead of the shorter one, and on that assumption states it is "a type of work to which factorial development is least suited."

Let me point out that if he gave a similar test with bromide printing in which one minute was known to be the correct exposure and a time of appearance quoted for this, and two other exposures of two and four minutes also given with their times of appearance, and followed the same reasoning (that the user would give the wrong exposure), he must also inevitably arrive at the same conclusion, that factorial development is quite unsuited for bromide printing.

To come down to real use of the factorial method for daylight (outdoor and indoor, developed together if need be). It is a big success used on these practical lines. All exposures calculated by meter. The sky or a bit of white in subject taken for the observation. Abnormal high-lights, as the sun in the evening sky, or over-exposed window in an interior, are passed over, and a lower high-light observed. Or in an abnormal subject with no high light, like a carved panel in dark wood, it is developed in the same dish for the same time as a subject with a normal high-light. In fact, the way to avoid the weak point in factorial development is to develop in batches, not less than four plates in one dish, to pass over any exceptional high-light, and to take the normal (or average) high-light for the time of appearance from which to calculate, and to give the same total time of development to all subjects in the dish.

A Long Experience in Method.

I have now developed gelatine plates for forty-five years, and have followed three systems:—

From 1876 to 1894 I used "inspection and judgment" only.

From 1894 to 1910 I used "factorial development" only.

From 1910 to 1921 I used "thermo time development" only.

The first change from inspection to factorial conferred an enormous advance in getting uniformity and obviating errors. The second change from factorial to thermo was taken because I wished to work with tanks and to do without a dark-room light, especially as I am red colour-blind.

Both the factorial and thermo methods have given me uniformity and tolerable certainty, but, to be quite frank, I think that I have secured slightly the largest proportion of "just right" negatives during the time I used factorial development. I have been "let down" several times in the thermo time method by plates or developer being different to what I anticipated, and the method does not give such a clear warning as does the factorial method.

As all this experience was with outdoor subjects, with church and other interiors, and as I have received scores of letters testifying to the success of others with factorial development in their hands, with similar subjects, I think I am justified in disputing Dr. Glover's claim that factorial development is "not suitable" for outdoor subjects. It is just on this work that it earned whatever reputation it possesses.

Perfecting Factorial Development.

I have repeatedly pointed out that the one weak point of factorial development could be obviated, and its other great advantages secured, if plate makers would issue with boxes of plates trial slips impressed with light images (in bars) of a standard light-impression from which to take the "first appearance" observation. This should be a standard multiple of the inertia of the plate, and it is a curious advantage that even if the "standard light" of different makers should vary, this light-impression would be the same standard for all if each used the same light to make the impression as was done to make the inertia test.

ALFRED WATKINS.

THE DEVELOPMENT AND PRESENT POSSIBILITIES OF AIR PHOTOGRAPHY FOR MAPPING.

DURING the war a great impetus was given to this latest method of survey. From balloons, or kites, air photography had been gradually evolving for 70 odd years, but the introduction of photography from airships and from aeroplanes, combined with the necessity of mapping inaccessible areas, led to the extensive use of air photographs for the revision of existing maps and for the detail survey over triangulated areas. The actual sphere of usefulness and limitations of the air photograph do not seem to have been grasped, however, by many more than the surveyors and some of the photographic staff employed on these war surveys. Even to these few the economic possibility of the method is still an uncharted region, for no statistics as to cost were kept, as far as I know, and as a consequence many extravagant claims as to the possibilities and economy of aerial photography for mapping have been made.

The present article is an attempt to outline, in two parts, the development of air photography as a survey method and the stage it has now reached.

PART I.—THE DEVELOPMENT OF AIR PHOTOGRAPHY FOR MAPPING.

Pre-War History.

The idea of replacing the personal work of the surveyor and topographer by photo-mechanical means dates from the time when both balloon and camera became available. We have literature on the subject which covers the last seventy years, and a fair measure of success was secured even before the war.

The camera, of many different designs, sometimes single, sometimes multiple, was used at lowish altitudes from fixed balloons or even kites. A recent German publication states that such a system had its first application in war at Solferino and its next at Richmond. Now the balloon does not lend itself to the taking of a series of plates more or less parallel to the earth's surface. This is obviously impossible if the balloon is stationary, and when it is free its movements are naturally erratic and more or less unforeseen. Photographs taken for mapping

...were then taken obliquely at an angle of ... (below the horizontal), of something of the order of 30 deg... ...ower to cover as much ground from a single station as ... The actual position of the balloon in space was ... fairly enough determined either by intersection from ground ... stations or by photographing a base in the form of ... (of known dimensions) immediately below the balloon. ... early experiments were very widely distributed ... Americans, Russians, Germans and Austrians all ... So far, these oblique photographs were regarded ... views of flat ground. No corrections could ... ...fluence of height or ground form. Towards ... last century a big stride was made by the ... photogrammetry from the air, whereby ground ... contours could, theoretically, be dealt with, although ... success can hardly be said to have been obtained ... 1905 and 1914, however, renewed progress ... special instruments were manufactured by Zeiss ... photography and for measuring angles upon ... negative or upon contact prints. It may be said that ... of both detail and contours from oblique photographs ... practically possible, but that the calculations ... too cumbrous and involved to hold out hopes of ... success. These latest developments were, I believe, ... German or Austrian. It will be seen, then, that on the ... break of war the Central Powers had secured a substantial ... lead.

War Experiences.

It is probable that photography from aeroplanes (as distinct from balloons) had reached the stage of development at which it began to be of use to the map-maker quite early in 1915 in all the larger armies. The first photograph used for mapping purposes by us, for example, was one of Neuve Chapelle, taken immediately after the battle. French and British methods developed side by side, and naturally took on the same complexion. German methods, influenced by their experience and hampered by the Allied command of the air, were somewhat different. In each case, however, they were governed by some common factors, which should be noted.

In the first place, air photography was not begun ... for mapping, nor was it, except in rare circumstances, ... exclusively directed to that end. This fact had ... influence upon the development of mapping from air photographs, because the surveyor was not consulted in the design of camera, or in the methods of photography.

Secondly, the airmen were never able to give up much space to the camera and its fittings, because they had to carry such armament, and were seldom allowed by enemy aircraft and by anti-aircraft guns to give their whole attention to photography.

These two factors were responsible for the fact that ... surveyors made few special demands upon the airmen, ... were content to take whatever photographs were ... without further ado than to ask for some lenses ... focal length than was usual for intelligence work, ... larger areas might be covered upon a single plate.

Still more important in its bearing upon our ... mapping from air photographs on the Western ... existence of a fairly universal trigonometrical ... a fairly complete series of cadastral plans ... No doubt the Allies were here in a happier condition ... Germans, but it was in the main true that ... the Western Front had a skeleton ready to hand ... only a photographic field sheet, as it were, ... theodolite. It is in the development ... photography, or of photography on a vertical ... angles measured by its aid, that progress must be ... In determining the positions of additional control points ... is of the photograph taken vertically downwards ... (the horizontal plate) that one naturally turns for the ... and correction of detail and such photographs ... procurable if the aeroplane can fly ... be mapped. One further item must be ... the French, Italians, Americans ...

...were ... necessary to the ... from ... ...ntinuously ... We ... on the subject ... photography ... the Western ... ...here than ... ...ring, the net ... photographs, ... spaces in the ... control points. ... ...ire of interest ... ...gaps in the con... ...of traversing, ...were as nearly as ... found that by putting ... ...a great ... ...and that ... great ... ...ally, be ... ...the sur...

eyor to reach so fair a degree of accuracy that for his 1 in 0,000 scale it was unnecessary to "rectify" each photo-graph, and the photo-traverses were pasted on to brown paper and then photographed up or down to the correct scale. So omparatively well did this photo-traverse scheme work, that where there were particularly few trigonometrical points, addi-ional control points were fixed by flying over and photograph-ng the sides of triangles, and thus fixing the position of the apices, just as the detail surveyor does by measuring the sides of triangles with his chain. A further point of interest lay n dealing with the distortions due to the steep and hilly nland areas. Wherever you meet with differences of height on the ground you must get differences of scale on your photo-graph, for the scale depends upon the height of the camera above the ground, and we get a certain amount of displace-ment which can best be understood by taking a concrete case. Supposing we take a photograph from a camera held rigidly vertical, nearly, but not quite, over some factory chimney. The ray from the lens to the top of the chimney, then, is not absolutely vertical. and if prolonged to cut the ground will fall to one side of, and not over, the base of the chimney. Now nothing that one can do to the resulting photograph will put the top of that chimney in its right position in plan, but the displacement becomes less as we get nearer to the centre of the photograph.

It is partly because of this trouble, due to differences of height and partly to the trouble of tilt, that experience led surveyors to use no more than one-third of each photograph and to arrange for a correspondingly larger number of exposures.

One more point of interest from Palestine (and Mesopo-tamia) is that air photo-topography proved most valuable, as one might have foretold, for mapping large Eastern towns, with their tortuous and narrow streets.

We may now sum up the experience gained by us in the war.

Firstly, we invariably had a network of triangulation on which to base our new surveys, and sometimes we had reliable old cadastral surveys also.

In the second place, all photography for mapping was done from a camera held as nearly vertical as possible; but

Thirdly, we had failed to evolve any means of holding it absolutely vertical, and practically every photograph was sensibly distorted in consequence.

Fourthly, we mapped at scales which varied from 1 to 6 in. to the mile. At the larger scales every photograph had to be rectified, and at the smaller scales, after considerable train-ing of the pilot, it was found possible to use photo-traverses.

Fifthly, we dealt with the problem as if the earth were flat (a safe assumption in Flanders!), and we evolved no method of actually measuring differences of height or of contouring, although we made use of the stereoscopic effect visible from two photographs which were partly of the same area.

In short, we had made it a quick and efficient, though not necessarily a cheap, method of detail survey at medium scales, but had in no way made it possible to dispense with the trig. observer or the contourer.

Our British experience is probably representative of that gained by the Allies in general. Indeed, German methods and achievements followed on much the same lines, with this essen-tial difference—that they did occasionally employ photogram-metric methods from the air, and were able to contour inacces-sible ground to some extent in consequence. We know this from articles which have appeared since the war in German surveying papers, but I am bound to say that one could not have suspected the fact from an examination of German war maps. It is probable, too, that much of the German mapping of our trenches and of the area in our occupation was done from oblique photographs.

Post-War Experience.

The important problems confronting the air photo sur-veyor of to-day have resulted in a good deal of research but little practical advance as yet. There are, however, three post-war air surveys of interest to mention. Most interesting is a survey carried out in North Africa by the French. The problem confronting the surveyor in this instance might occur frequently in war. The French outposts ran along the edge of a very mountainous, difficult, and hostile country, which could not be entered by surveyors. It was desired to map a strip of 60 kilometres broad. Triangulation had been pushed up to the outpost line. The programme of work may be considered under the headings:—

Additional trig. control: Fourth order.
Air photo-control: Fifth and sixth orders.
Air photo-topography.
Air photo-contouring.

The first stage was to intersect with the theodolite a number of peaks, and these are classed by the French as the fourth order of control, and serve as the base for the fifth and sixth orders. To carry out these further controls planes ascended nearly, but not necessarily quite, over trig. points, and took panoramas as nearly in a vertical plane as possible. These panoramas included various already fixed peaks, and the position of the camera at the moment of exposure was resected from these known points. The positions of exposure were then plotted and forward rays to other points were drawn in. By repeating these panoramas at a variety of points and at different altitudes a number of points of the fifth order were established. Points of the sixth order followed in much the same way, but with the difference that they were intersected by rays measured on panoramas taken during flights over the ground to be mapped, in conjunction with the air photo-topography, and corresponding to marked hori-zontal plane photographs. The photo-topography was done on a cinematograph film, exposures being governed mechani-cally, and the result, controlled by its sixth order interpola-tions, was plotted from compiled and mounted photo-traverses. Here we see, then, a further development of Hamshaw Thomas's traverse scheme. Finally, heights were calculated from the plotted distances, and from vertical angles measured on the vertical panoramas, starting from the height as given on the barograph in the aeroplane. It is noteworthy that no claim is made of an accuracy greater than that wanted for a survey on the 1 in 200,000 scale, and it is probable, I think, that errors in linear measurement between control points are of the order of 1/500 (which may there-fore reach a sensible total), and errors of altitude of the order of ± 100 ft.

Quite recently, in an Engineering Supplement of the "Times," we read of American experiments in air photo-hydrography and air photo-topography. Little progress seems to have been made in the former, for it was found that contrast in tone on the photograph did not correspond neces-sarily to relative depth, but followed more generally the colour of the bottom.

The air photo-topography, however, proved its value in the revision of a coastline strip, which was chosen as one of the natural subjects for this method. Here again we find the air photo-traverse employed without rectification of the indi-vidual photographs. A noteworthy feature of this survey is the reliance upon a camera controlled by gravity and fitted with spirit-levels—which adds another confirmation to the soundness (within certain limits) of our war procedure in Palestine.

The third and last survey to mention is one reported in a German work on photo-grammetry from the air. A party of trig. observers preceded the photography and fixed an addi-tional number of points in the area in question, and another survey party named, and revised on the ground, the plotted map. Air photography was entrusted with the fixing of addi-tional points from the measurement of horizontal and vertical angles on negatives taken obliquely, with photo-topography partly from these obliques and partly from horizontal plane photographs, and with photo-contouring.

The most interesting feature of this survey, and of the literature which deals with it, is that it establishes definitely that the position (and height) of exposure in space, and the direction and magnitude of tilt, can be fixed easily enough

if three known points appear on the photograph, and it describes instruments for calibrating the lens and for angular measurement on the negative (which is tilted to correspond to its position at the moment of exposure).

PART II.—THE PRESENT POSSIBILITIES OF AIR PHOTOGRAPHY.

It will be convenient to a résumé of the subject to adopt the following headings and to omit an unnecessary repetition of the prefix "air."

1. Photo-control.
2. Photo-traverse.
3. Photo-topography.
4. Photo-contouring.

1.—Photo-Control.

All previous surveys have emphasised the fact that photo-control cannot give an adequate support for a map, except for short distances. It may follow either from oblique or from vertical-plane photographs, and in either case, to be of value, from refined measurement on the plate. It postulates interpolation from previously fixed points appearing on the plate (and a determination of the magnitude and direction of tilt in the case of obliques). A high order of accuracy in measuring angles from photographic plates has been obtained for some purposes, but so far photo-grammetry has not given us much precision for surveying, and, with the added difficulties of resecting in space and then rectifying it is not to be expected that the error of linear measurement will fall below something of the order of 1/500, if indeed it falls so far. It is, in my opinion, highly unlikely that any graphic interpolation depending on geometrical construction or upon any mechanical device will give us results which will do more than hang two or three photographs together. To mention one point alone, the lens itself must be carefully calibrated, and the corrections which result to the position of points on the photograph may assume serious dimensions. In German practice the angular measurement on the plate follows from observation with a specially-designed theodolite looking through the lens used in the aeroplane (or one precisely similar) at the plate which is set to the actual angle of tilt.

At this present moment we have no experience in the provision of a photo-control, although the matter is in capable hands, and we may hope for speedy developments.

One may say at once, however, that no photo-control is likely to do more than amplify the trigonometrical control, or carry us some few miles from it, and that only where suitable and identifiable points are to be seen on the negative.

No photographic method will give control points in a forest, for example.

2.—Photo-Traverses.

A photo-traverse is a form of control from the horizontal-plane plates, and has proved its utility, but it must be remembered that it can give accurate results only in flat country. Its value must depend largely on the previous training of the pilot and upon the vertical position of the optical axis. Now to ensure the latter we can, at present, do no better than hope for a steady "air speed" and rely upon gravity and the spirit-level. It is suitable for scales smaller than 1 in 20,000. A gyroscopic attachment has often been discussed, and may yet appear, however, in which case greater accuracy may result.

3.—Photo-Topography.

With our control (and possibly traverses) plotted, we now turn to the detail, and here we must think in the first instance of scale. No photograph will give a ground plan of a thick hedge, or the boundary of a wood, or of a house with eaves, etc. It can, in fact, give only what it sees, and, as has frequently been pointed out, it cannot hope to give us cadastral plans whenever overhanging detail is met with. For large-scale maps (shall we say from 1/5,000 to 1/20,000) each photograph must, at present, be "rectified," but if we secure a good gyroscopic or other device for holding the optical axis vertical, we may escape this laborious step. Indeed, we must do so, on economic grounds, if photo-topography is to compete, over ordinary country, in the open market with the surveyor. For small scales and in flattish countries trained pilots have already shown us that "rectification" is unnecessary, except perhaps under war conditions. In Palestine the errors in position due to the hilly nature of the ground were assessed at a general figure, of about 70 metres, and one can see that special rectification must follow in mountainous country.

4.—Photo-Contouring.

To be of any accuracy, heights must at present be calculated from vertical angles measured on the plate and a previously computed height of the camera at the moment of exposure. Considerable calculation is necessary, but as a method it is feasible enough, and in the recent German survey, mentioned above, it is claimed that errors of height varied from one to two metres. It may become quite practicable to rely on stereo-photo-grammetry applied to two photographs "placed" on the detail and rectified, but we have no experience as yet in this method.

Finance and Summary.

Now, having discussed our various stages, let us turn to finance. One may assume that the taxpayer will remain indifferent as to which of his pockets the money comes out of. His chief pre-occupation will be the gross total. It serves no purpose, therefore, to assume, as recent articles have done, complacent departments which may, by timely loans of men and material, diminish the apparent total.

I do not myself see how the price per plate can be less than 15s. or so, if we allow for expenses in rectification and in fitting to the map. It is, however, useless to elaborate this point here, for there are no recorded figures to show us exactly where we stand. We must await experience. We can say, however, with certainty, that except in certain extreme types of country we may economise in time, but are unlikely to economise in money. These three points will help to realise the position:—

1. The Ordnance Survey is a standing proof that cadastral plans at a scale of 1 in 2,500 can be surveyed at a cost of £12 18s. a square mile (pre-war figure).

2. Our pre-war Colonial Surveys show examples of fully completed topographical surveys at 1 inch to the mile for 10s. a square mile, and ¼ in. to the mile for 5s. per square mile.

3. The inevitable preliminary to an air-photo survey is a triangulation and the inevitable sequel a visit to the ground for examination, naming, etc.

To sum up the present position we may then say:—

(a) As far as can be seen at present, air-photo surveys cannot give us cadastral plans.

(b) Medium scales (1 in 10,000 to 1 in 40,000) offer the most favourable sphere.

(c) There is no likelihood that photo-control can take the place of triangulation except within small areas.

(d) A visit to the ground will always be necessary for examination and naming.

(e) Photo-survey has taken its place as a method, and a useful one, but has not replaced, and does not seem likely to, except in special cases, the older methods.

(f) The Classes of survey for which air-photography is especially suitable seem to be:—

i. Where the ground to be surveyed is inaccessible to the surveyor.

ii. Revision for economic and statistical purposes where accuracy is not essential (e.g., areas under cultivation, index maps to properties, etc.).

iii. Plans of large towns, archæological sites, etc., at medium scales.

iv. River channels, estuaries, and deltas, where shifting detail and difficulty of survey combine to obstruct land survey.

(g) Existing methods of air survey have been sufficiently exploited already to allow of a fair estimation of their possi-

bilities. Progress will come most surely then from research and experiment directed upon the following (amongst other) points:—

i. The ensuring of the verticality of the optical axis.
ii. The measurement of magnitude and direction of tilt.
iii. Measurement on the plate of horizontal and vertical angles.

H. S. L. WINTERBOTHAM.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Photographing Blue Prints.

THIS work looks so easy, for a "blue print" is generally a dark blue, or fairly dark, but in reality it is a difficult proposition to anyone unaccustomed to the work. In practice there is only one plate that can be depended upon for emulsion to produce a good printing negative. The one plate is a backed process panchromatic; this with a red filter will give the operator a fine black and white negative.

These plates must be manipulated in total darkness, unless the photographer possesses a safelight, but for occasional work this expense can be overcome. But be quite sure there is no white or actinic light creeping in anywhere; and after the plate has been safely housed in the dark-slide, wrap the box containing the remaining plates in the usual black paper, tying a string round the same.

The plate being now safe in the dark-slide, proceed to focus to scale with the red gelatine filter fixed in position behind the lens with one or two drawing pins. Some operators unscrew the front lens and fix the filter in front of the diaphragm or stop, but it is best not to interfere with the lens, half a turn one way or the other may affect the definition. Others adopt a means of fixing the filter in the front, which is useful if you have glass filters, but modern "flats," as they are termed, run to pounds in cost. A 3-inch square gelatine filter is a convenient size, and cost before the war 3s.

The "blue print" is most conveniently photographed if placed in a printing frame with a glass in front. This is so easily shifted, whereas if drawing pins are used it means taking out 10 or 12, or even more, if the "blue print" is a large one and an alteration needful.

Finally, attend to the carbons, if you have not done so, as they may be required to run for fifteen minutes. The larger the reduction the smaller or less the exposure, so that as little as five minutes may suffice.

It is now presumed you have focussed up through the red filter, inserted the dark slide, seen to your lamps; now cap the lens and insert diaphragm *f*/45, but if the reduction is very considerable, say a 24 x 20 or 20 x 16 to postcard or quarter-plate, then *f*/64 is best. On the other hand, if you have to make a negative enlargement or only a reproduction the same size *f*/32 is correct, for that at the same size is equal to *f*/64 so far as aperture to camera extension is concerned.

Be sure to see that the light of the lamps is not reflected back into the camera from the printing frame. Take out the focussing screen, cover head with a dark cloth, and then look first one side and then the other. If the light shines in your eyes you may know it will spoil the negative. Alter the lights (do this with the open lens), re-insert the stop, and place the cap on the lens. Then insert the slide, draw the shutter and expose, taking a seat to avoid vibration. Have pencil and paper, and put down the exposure so that if a second plate has to be used there will be no doubt in your mind as to how long you gave the first. Full exposure with at least *f*/32 (but *f*/45 will generally be found better), full development, ample fixing, the usual washing and drying, a good, glossy, contrasty paper, and you can send the prints home with the knowledge that you can charge a good price.

The exposure may be anything from 3 to 15 minutes. Now, taking the dark-slide into the developing room, have something ready to cover over the dish, as few dark rooms are absolutely actually light-proof, and fasten the door. Insert plate in developer and cover it over, having previously taken the time. Then count the seconds, and, when five minutes is up, check yourself by the watch. It is well to let the plate develop for at least two minutes motionless, and then keep the plate well rocked to prevent any of the backing from settling on it. At the end of five minutes, turn on the red or green light, and just glance at the plate. Most likely you will give it another 60 seconds, then turn on the water into the developing dish, and give the plate a good swilling, take out, place in fixing bath, but do not leave the room unless you can gain access to the outer world without admitting actinic or white light, for even in the hypo these panchromatic plates are remarkably sensitive; it is very desirable that a good fixing be given; 15 minutes is none too long. I remember a case in which a plate seemed longer than usual in fixing. I turned on the light behind the yellow lantern. I held a 24 x 20 plate to the light, but a patch in the corner was not fixed; it caught the light, although perhaps only exposed to it for 10 seconds. After washing and drying, that corner was found the next morning to have a dense patch which caused a lot of trouble, all of which might have been avoided by five minutes more in the hypo.—A. C.

FORTHCOMING EXHIBITIONS.

January 22 to February 5.—Northern Photographic Exhibition. Latest date for entries, January 15. Particulars from the Hon. Secretary, Liverpool Amateur Photographic Association, 9 Eberle Street, Liverpool.

January 27 to 29.—Birmingham Photographic Society. Particulars from the Hon. Secretary, Philip Docker, Birmingham Medical Institute, Edmund Street, Birmingham.

February 14 and 19.—Leicester and Leicestershire Photographic Society. Latest date for entries, February 5. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

February 19 to March 5.—Edinburgh Photographic Society. Latest date for entries February 10. Particulars from the Hon Secretary, G. Massie, 10, Hart Street, Edinburgh.

February 19 to March 12.—Scottish Salon, Dundee. Latest date for entries, January 31. Particulars from the Hon. Secretary, James Slater, Rosemount, Camphill Road, Broughty Ferry.

March 16 to 19.—Hackney Photographic Society. Latest date for entries, March 1. Particulars from the Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Latest date for entries, March 17. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9..

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—We are glad to see that our Birmingham friends are raising their banner again by holding their annual exhibition at the galleries of the Royal Society of Artists, New Street, Birmingham, from January 27 to 29 next. On this occasion the exhibition will be limited to the work of members, except in two classes, which are open to residents in Warwickshire, Worcestershire, or Staffordshire. We daresay the Society is right in the view that the day has not yet arrived for resuming the open exhibitions which in former years were a notable feature of its activities, and at which on several occasions new lights in the pictorial world would first make their appearance. But the many able members within its own ranks will no doubt be fully equal to bringing together a strong exhibition of both pictorial and scientific work.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, December 29 to 31, 1920 :—

OPTICAL PROJECTION.—No. 36,277. Optical projection system. P. Blackman.

FILMS AND PLATES.—No. 36,415. Photographic films and plates. Dye Impression Photos, Ltd., and W. H. Edridge.

CAMERAS.—No. 36,618. Photographic film cameras. K. Koehl.

OPTICAL PROJECTION.—Nos. 36,600 and 36,601. Optical projection apparatus. J. M. McAlery.

CAMERAS.—No. 36,602. Photographic apparatus and cameras. J. M. McAlery.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

NATURAL BACKGROUNDS IN PORTRAITS.—No. 153,111 (August 7, 1919). The invention relates to photographic apparatus for taking pictures with a background of any desired character.

The object of the invention is to construct apparatus for carrying out the known method of photography in which a given subject is first taken on a sensitive plate with a dark background and the usual lighting scheme, and thereafter a bright background is substituted, and the same sensitive plate in the camera exposed thereto through a positive plate in contact with the sensitive plate.

A transparent platform is provided upon which the sitter is posed, say a platform of glass, provided with a dark background formed, for instance, by one or more wings sliding transversely on rails and operated by suitable levers and cords from a point adjacent to the camera. Behind this movable background is located a source of light, say a sheet of white linen, behind which are mounted a series of lamps adapted to shine through the sheet when required, and also capable of being brought into action by suitable levers and cords operated from near the camera, preferably at the same time as the removal of the dark background. A transparent glass plate placed just behind the sitter may or may not be used for posing purposes, but an essential point of the invention is that the transparent platform should allow of the light from the bright background passing all around the posed figure to the camera lens, especially under the base of the figure.

To prevent an abrupt division where the outline of the figure is set within the background in the final picture a novel vignetting device may be employed which consists of an ordinary vignetting card, but combined with a corresponding semi-transparent plate which assures a hazy effect upon the negative when placed in the path of the light-rays from the bright background to the camera.

It will be noticed that the figure is on the opposite side of the camera lens to the positive of the background, and it is during the exposure of the latter that the semi-transparent vignette plate acts, and preferably it cuts off or only partly exposes the transparent base which would otherwise pass light from the background beneath the posed figure.

Advantageously the camera may be mounted within a movable camera room in which the photographer works, which room he can move along rails by suitable lever mechanism, and from which room he can not only change the background, but at the same time switch off the front lighting member and switch on the rear lighting members.

In operation, the photographer, having posed the sitter on the transparent platform with the dark background behind, takes a photograph on his sensitive plate in the ordinary way, the focussing of the camera to get the necessary clearness and size of picture being obtained by the photographer moving the camera room bodily on rails on the floor. This done, he then pulls another lever which removes the dark background, switches off the front lights and at the same time lights up the bright background behind it instantaneously by mechanism for the purpose, and quickly inserts his background positive plate in front of his negative plate or film, and the bright background causes a print of the positive to be transferred to the negative except on the portion thereof covered by the image of the sitter.

The vignetting arrangement is placed outside the camera room, being covered by a black ground during the first exposure, which ground is pulled away, leaving the semi-transparent glass

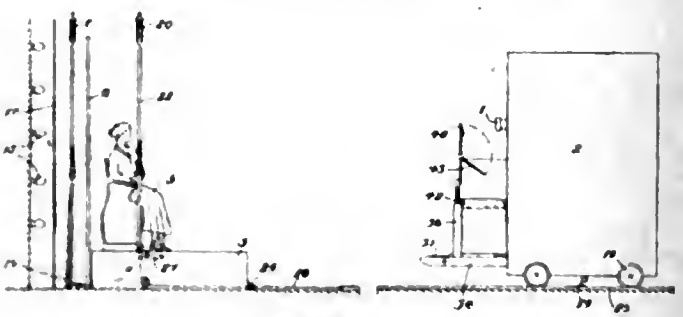

Fig. 1.

vignetting plate lighting up the background positive, but delineating the silhouette of the part of the sitter which it covers.

By this invention a most natural effect is produced, which can be carried so far by means of the vignetting arrangement as to cover any portion of the figure of the sitter by the background that many be desired, and a very pleasing result is thus obtained.

In the drawings, 1 is the camera supported on the usual stand in the movable camera-room 2. 3 is a platform constructed with a glass top 4 in order that it shall be transparent. 5 indicates the subject to be photographed in the form of a figure in a chair resting on the platform 4. 6 is a sheet of glass immediately behind the sitter 5, which may be useful for posing the latter in accordance with the ideas of the photographer. 7 is a rail extending completely across the platform

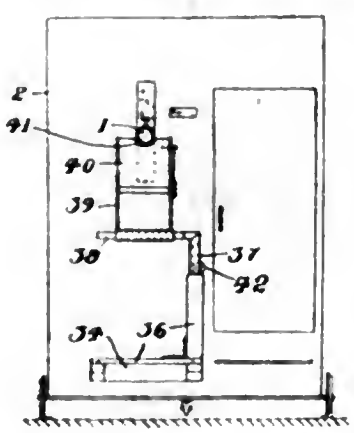

Fig. 2.

but high above and carrying, by means of the pulleys 10, 11, a pair of screens 8, 9 formed by frames covered with black velvet, the frames being attached by cords 14, 15 to balance weights 12, 13 respectively, and being further provided with interlocking catches 16, so that they may be drawn together and connected at their meeting edges. Immediately behind this black screen 8, 9, is provided a stationary frame over which is stretched white linen or other fabric forming a luminous surface 17 when the rear lights are illuminated. Conveniently upon a second ceiling rail 20, a pair of side wings 21, 22, also formed of black velvet stretched on a frame, may likewise be connected to counter-weights 23, 24. These side wings may conveniently

be kept in place by means of catches 26, 27 carried on the side of the platform and operated against a spring by means of a cord 28 and suitable guide pulleys such as 29, 29, the cord being carried into the interior of the camera room 2 so that by withdrawing the catches 26, 27 the side wings are withdrawn. Conveniently also the cord 30 connects with the cord 28, and

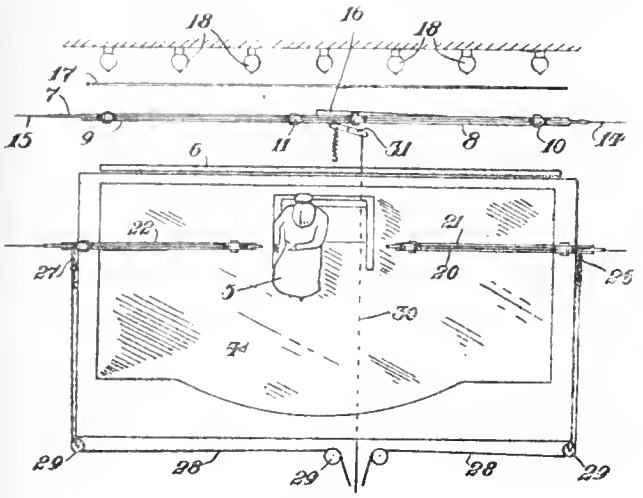

Fig. 3.

by operating the pivoted lever 31 pushes one side of the back screen 8 away from engagement with the portion 9, whereupon the weights 12, 13 cause the withdrawal of these screens forming the black background. At the same time a continuation of one of the cords 28 or 30 operates a switch which puts on the lights 18 and puts out any lights there may be forward of the sitter 5. Simultaneously the operator within the camera room 2 places a transparency or positive plate of a suitable scene in front of the dry plate, whereupon the light, showing through the screen 17, photographically affects the sensitive plate through the transparency and exposes the image therefrom on the negative except where the light from the luminous surface 17 is stopped out by the figure of the sitter 5, which therefore remains as in the original exposure; no other exposure of this figure 5 occurs because the forward lights which made the original exposure are put out and no reflection of light therefore occurs from the sitter.

Referring to figs. 1 and 2, 34 is a bracket projecting from the dark room 2 upon which are rods 35 carrying the frame 36, of

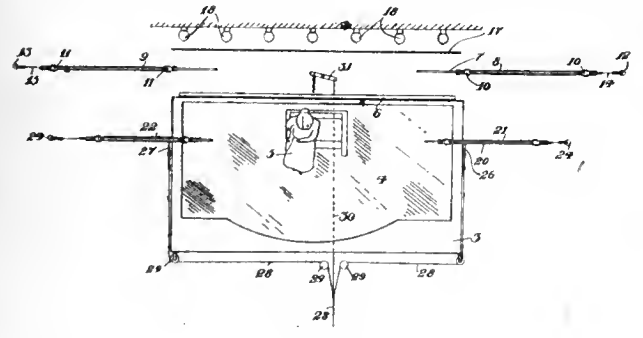

Fig. 4.

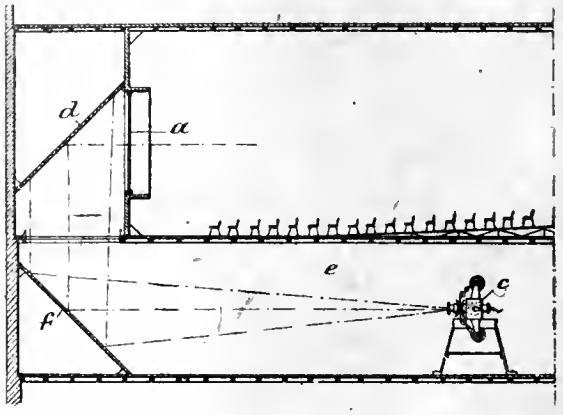
which one corner is formed as a hollow upright and receives the leg 37 of an angular support having the transverse leg 38 upon which slides the frame 39 provided at its upper end with the semi-transparent screen 40 preferably of ground glass having the vignetting recesses 41 removed therefrom. The frame 36 may be slid along the rods 35 to suit the longitudinal position required for the vignette frame 40, and the height thereof may be adjusted by means of a rack and pinion 42 operable by any convenient means from within the camera room.

It should also be noted that the camera room 2 can move to and from the platform 3 by reason of it being carried on wheels 19 working on the rails 25.

The vignetting glass 40 is provided with an opaque cover 43, which is used to cover up the surface 40 when the first exposure is made, and the purpose of the vignetting device is that, when making the second exposure in order to obtain the background on the dry plate, it may be made through the ground glass 40 surrounding the vignette recess 41, which will permit a reduced amount of light to pass through and thus enable any boundary line between the actual image of the sitter and the image of the background to be softened so as to proceed from one image to the other without a hard and fast division. For example, supposing the figure of the sitter is given a background showing a portion of sea, it may readily be arranged so that portions of the figure are hidden by the sea, with the result that the effect is exceedingly natural and hardly observable as not being taken in the actual sea. Stuart Elwin Neame, 4, Onslow Place, South Kensington, London.

Optical Projection.—No. 147,340 (July 14, 1919). The invention relates to the projection of pictures in rooms lighted by daylight or by artificial light, and consists in placing the projecting apparatus in a room above or below that in which the screen is viewed, the images being thrown on a translucent screen by means of an inclined mirror arranged behind and adjacent to the screen path for the light is greatly extended. This arrangement is possible if there is a suitable cellar *e* below the theatre. The projecting apparatus c can be placed in the cellar, and it is only necessary that there should be a second mirror *f*



which deflects the rays of light from the horizontal into the vertical direction. Petra Aktiengesellschaft für Elektro Mechanik, Niederwallstrasse, 18-20, Berlin, C. 19, Germany.

The following complete specifications are open to public inspection before acceptance :—

Printing Boxes.—No. 155,790. Boxes for photographic printing. E. Golesceano.

Cinematography.—No. 155,793. Cinematograph apparatus. Petra Akt.-Ges.

Cinematographs.—No. 155,764. Cinematographs. J. Szczpanik.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Sensima.—No. 408,884. Photographic chemicals, photographic plates and photographic films. L. Gevaert et Compagnie, 23, Septe Straat, Vieux-Dieux, Belgium, manufacturers of photographic materials. October 19, 1920.

Negopock.—No. 408,817. A folding photographic camera. The Russian Company for Foreign Trade, Ltd., 57, Shoe Lane, London, E.C.4, merchants. October 18, 1920.

Ossal.—No. 374,868.—Irradiating or lighting-up screens for Röntgen-ray work, being for surgical or curative purposes. Chemische Fabrik von Heyden Aktiengesellschaft, 57, Leipzigerstrasse, Dresden, Saxony, manufacturers. September 26, 1916.

New Books.

Pearose's Annual, 1921. Edited by William Gamble, F.R.P.S.. London and Bradford: Percy Lund, Humphries and Co. 10s. 6d. net.

We are glad to see this annual review of the photo-mechanical crafts making its appearance with almost its former punctuality. For twenty-three years, first as the "Process Year Book," under Mr. Gamble's editorship, it has made itself a repository of technical contributions by leading process workers, and, moreover, has discharged what is perhaps a still more useful function, namely, that of recording, in the shape of its numerous supplemental plates, the actual commercial progress which is made year by year in processes of reproduction in monochrome and colours. In both of these respects the current volume takes a fully deserved place among its predecessors. The editor's review of the present technical status of reproduction methods and of possible development is perhaps the most interesting item of the literary contents. Mr. Gamble, whose touch with the process trade is of the closest, cannot record striking developments in any of the existing processes, but he casts a prophetic and, as some may think, a somewhat over-sanguine glance into the future, and foreshadows great developments, not simply in photo-mechanical methods, but in the displacement of established systems of type-setting by photographic and photo-mechanical processes. He refers to several inventions which have for their object the production of printed text by methods of offset-litho or rotary photogravure, that is to say, by systems which reject the customary operation of setting up type by hand or by a composing machine. We don't suppose that linotype operators feel their occupation to be immediately threatened by the prediction of the "photo-comp." who will use an automatic camera for the production of letterpress letter by letter by photographic processes, and will thus cut out the whole machinery of setting type by hand or by the casting methods of the Linotype or the Monotype. It would indeed be a whirligig of destiny if almost the least organised body of workers (photographic assistants) were to prove themselves the displacers of the most firmly entrenched body of trade unionists. However, Mr. Gamble writes hopefully, and Mr. Arthur Dutton, the inventor of the "Photoline" process of typeless printing, has something to say, but no more than to make one wish he had written at greater length, on this new application of the photographic process.

Individual contributions in the volume are by Mr. Charles T. Jacobi, who has an interesting account of the Plantin Museum at Antwerp; by Messrs. W. J. Smith and E. L. Turner, who write of slide rule and graph methods of calculation in process work; by Mr. R. B. Fishenden, who has a note on high-light processes in photo-lithography; by Mr. James G. Gray, who records progress in intaglio engraving machines, and by Mr. H. Mills Cartwright, whose contribution is on the use of irregular grained screens for photogravure. It will thus be seen that intaglio and lithographic methods secure the lion's share of notice in the literary part of the "Annual," and the same may be said of the many illustrations of process work. The frontispiece is a fine specimen of photogravure in colours by the Rembrandt Intaglio Company, which contributes also a typical example of its work in monochrome in the shape of a reproduction of a portrait by Greuze. Messrs. Blades, East and Blades, Harvey Barton and Company, John Swaine, and Messrs. Penrose themselves are other contributors of rotary photogravure prints. The examples of half-tone are chiefly in colour and well illustrate the present high level of work for catalogue or book illustration. Altogether, Mr. Gamble and those who have supported him with contributions or illustrations may be congratulated upon bringing together a most valuable work, in the production of which they owe a great deal to the taste and skill of the printers and binders, Messrs. Percy Lund, Humphries.

Photographic Companies.—Messrs. Jordan and Sons, of Chancery Lane, in their table of company registrations during the year 1920, state that during the first six months 28 private companies were registered with a total capital of £249,783; during the second half of the year 17 private companies were incorporated with a capital of £132,750.

New Materials.

Sensima Ultra-rapid Plates. Made by Gevaert, Ltd., 115, Walmer Road, North Kensington, London, W.10.

Hitherto the firm of Gevaert has not issued a plate of "ultra-rapid" sensitiveness. Since the addition several years ago of the manufacture of plates to that of the many varieties of printing papers, for which they have secured the highest opinions, they have been content to establish their good name in reference to materials for negatives by means of a series of plates of more moderate speed, ranging from 225 to 275 H. and D., and including an orthochromatic and a non-screen variety in the list. But, rightly or wrongly, the cry is for extreme speed, and it was inevitable that Messrs. Gevaert, in taking their place with British makers, should issue a plate of extreme speed. That they have not done so until now may fairly be taken as an indication that the step has not been made until the resources of the Antwerp factory had been applied to produce an emulsion deserving the reputation, as regards speed and other qualities, which their other manufactures have consistently maintained.

The new plate, the "Sensima," is now issued as of the extreme speed indicated by the H. and D. rating of 500, that is to say, about twice the sensitiveness of their "Special Sensitive." The nomenclature of plates is unfortunately not always a clear guide to relative speed. A maker adopts an appropriate title for his most rapid plate, and then, when he goes one better, is sometimes hard put to it to find a name for one still more rapid. But after all there is as little in the name of a plate as in that of anything else; the photographer, and particularly the portrait photographer, regards it simply as a reminder of the brand which he has found to fulfil his requirements. And our own experience of the new Gevaert plate tells us that he will not be disappointed in memorising "Sensima" as a synonym of extreme speed. We think that exposures at least as short as those permitted by any other may be given to it, and there will be no fault to find in its rendering of gradation in the less illuminated parts of the subject. Moreover, it develops readily to good vigour and, for a plate of its speed, stands a surprising amount of forcing in development when exposure has been below even the minimum which it may receive. It is evident that the plate represents the most modern skill of the emulsion maker. Messrs. Gevaert can confidently class it with their earlier issues and with their printing papers as the product of the most refined scientific manufacture; and to those who have regularly employed these materials perhaps no more convincing statement of its merits could be made.

Manchester Amateur Photographic Society.—A courageous step has been taken by the Manchester Amateur Photographic Society in raising its annual subscription from 7s. 6d. to £1 1s. For several years past the funds for the increasing costs of running the Society have been raised by various special efforts and appeals, but it has been unanimously decided by the Council of the Society to place the subscription at a figure which will remove the necessity for these irregular means, and will, moreover, allow of a forward movement being undertaken which has, in a measure, been forced upon the Society by the impending termination of the lease of its present premises. The opportunity now offers of securing a better suite of rooms in the same building, where more ample accommodation for lectures will be available, as well as rooms for enlarging and developing, and also, it is hoped, an electric studio. Moreover, if the membership continues at a sufficient number, it is hoped to keep the premises open during the day as well as in the evening. It is evident from all this that the Manchester Society clearly recognises the important work which it can do for the many amateur photographers within the crowded Manchester area, and we cannot have any doubt that those who are already members, as well as many who at present are outside its ranks, will rally to its support, and thereby will contribute to the increased usefulness of a centre of photographic activity which in the past has rendered most valuable services.

Commercial & Legal Intelligence.

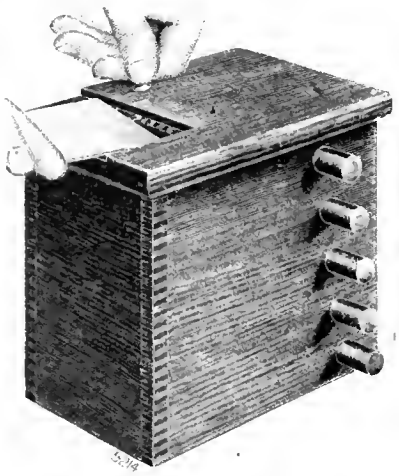
NEW COMPANIES.

ALEXANDER WILSON (BLYTH), LTD.—This private company was registered on January 3 with a capital of £2,000 in £1 shares. Objects: To take over the business of an optician and dealer in photographic apparatus and accessories, carried on by A. Wilson at 32, Regent Street, Blyth, as Alexander Wilson. The first directors are: A. Wilson (permanent), 11, Barnard Street, Blyth; C. S. Hiles, 112, Gladstone Street, Blyth. Secretary: C. S. Hiles. Registered office: 32, Regent Street, Blyth.

New Apparatus.

A Negative Numbering Machine. Made by Houghtons, Ltd., 88-89, High Holborn, London, W.C.1.

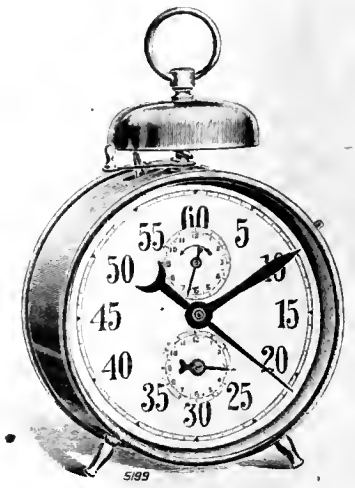
A DARK-ROOM accessory, primarily for the professional photographer, has been introduced by Messrs. Houghtons for the purpose of providing a photographic means of impressing any desired series number upon a plate before exposure. The machine is really a photographic version of the familiar perpetual dating stamp. It consists of a closed box with a light-tight cover, and containing five narrow endless bands, each of which includes a strip of celluloid negative bearing the numerals 0 to 9. Each band can be separately adjusted in position by an outside winding handle over an aperture below which is a small electric lamp, worked by a dry battery. Thus any required number from 1 to 99,999



may be arranged over this aperture. The lid of the box has in it a slot corresponding in size and position with the row of figures brought immediately below it by suitable adjustment of the numeral negative bands. It is also provided with a right-angle stop or rebate into which the negative is simply put, film down, of course, and exposure then made through the composite numeral negative. The required number is thus obtained on the extreme margin of the negative on development. The apparatus is an ingenious attempt to provide an indelible numbering of negatives. It is supplied, complete as we have here described it, price £2 15s.

The Ensign Dark Room Clock. Sold by Houghtons, Ltd., 88-89, High Holborn, London, W.C.1.

THIS new pattern of a dark-room clock is most conveniently designed, and has all the movements necessary for dark-room work, that is to say, for fixing, washing, and similar somewhat protracted operations, as well as for exposure and development. The 4-inch dial of the clock is boldly lettered, as shown in the drawing, in 5-second intervals, the large hand taking one minute to traverse the outer circle of numbers. At each passage of the finger over the 60-second mark a bell is rung, this movement providing a useful warning of the end of periods of time between one and two minutes. At the same time the smaller hand, which moves over this outer



scale, registers minutes, whilst the small dial in the lower part of the face registers hours, and is divided for reading with sufficient accuracy to one-eighth, or at any rate one-quarter of an hour. The upper small dial permits of the clock being set to ring the bell at the termination of any required period. It will thus be seen that these features comprise all those which are of practical service in the dark-room; and it should be added that there is also fitted a start and stop lever, and also a movement for putting the gong out of action. A clock of this universal type undoubtedly serves a very great many useful purposes and adds a desirable element of certainty to almost every photographic process. The price of the clock is 27s. 6d.

PHOTOGRAPHIC PHOTOMETRY AND THE PURKINJE EFFECT.—A paper on this subject by F. E. Ross, of the Eastman Research Laboratory, appears in the "Astrophysical Journal," of September, 1920. According to an official abstract, the increase in diameter of a star's image is proportional to the logarithmic increase of exposure time, and it is proposed that when this is measured with an artificial star the coefficient of increase shall be called the *astro-gamma* because of its analogy with the factor which is termed *gamma* in photographic work. Both gamma and astrogramma are dependent upon the wave-length, and photometric measurement of stars made photographically must take into consideration this variation of gamma and astrogamma with wave-length. These effects are considered in the paper. Some results obtained with long exposure where the light source is very weak are also given. The theoretical considerations involved are dealt with here.

LIGHT-INTENSITY AND EXPOSURE TIME.—A paper on this subject by F. E. Ross, of the Eastman Research Laboratory, appears in the "Journal of the Optical Society of America," of September, 1920. According to an official abstract the equations connecting photographic density with exposure which have been proposed by Abney, Hurter and Driffield, Elder and Channon are critically discussed. In particular certain theoretical objections to the Hurter and Driffield formula are advanced. The author proposes a new formula, the underlying idea being the separation of the grains of an emulsion into different classes, according to their sensitiveness. The thickness of the emulsion is taken into consideration, and is measured not in microns but by number of layers of grains. The mass-action equation is assumed to hold for each group. All formulæ are compared with two types of measured characteristic curves, in one of which the "toe" is prominent, in the other, it is almost absent. It is difficult to include the characteristics of "toe" and "shoulder" in any simple algebraic formulæ. These peculiarities point to the existence of secondary phenomena.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, JANUARY 16.

South London Photographic Society. Visit to Bankside

MONDAY, JANUARY 17

Bradford Photographic Society. Yorkshire Photographic Union Night. Prints and Slides.

North Middlesex Phot. Soc. Demonstration Wellington Materials.

FRIDAY, JANUARY 21

Bedford Camera Club. "Psychic Photography" (Ladies' Night.) S. W. Woolley.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, January 11, the president, Dr. G. H. Rodman, in the chair

The president announced that the Council had awarded the progress medal of the Society to Mr. F. F. Renwick for his researches into the chemistry and physics of photography. He felt sure that members of the Society would heartily approve this tribute on the part of the Council to the value of the extensive scientific investigation work which Mr. Renwick had done. Members present endorsed this view by their applause.

Mr. Julius Rheinberg then read a paper entitled "Some New Directions for Photographic Research," in which he dealt with the physical changes occurring in colloid substances rendered sensitive to light. He instanced the applications of a change in physical properties of bichromated colloid to the manufacture of mosaic colour filters for screen-plate colour photography, and gave a general and somewhat rapid description of the details of a process which he had worked out, and which depended upon variations in permeability of a colloid coating. Mr. Rheinberg gave examples of the use of the much-neglected method of rendering a colloid insoluble or impermeable by means of ferric salts, and then, by exposure to light, producing a greater or less degree of solubility or permeability.

The lecturer also referred to experiments which he had carried out for finding a solvent of pyroxyline which was free from the objection of the varying rates of volatilisation possessed by alcohol and ether as ordinarily employed in admixture for this purpose. He had found that methyl alcohol could be used as a single solvent, but had the drawback of yielding an opalescent collodion film. This latter defect, however, could be avoided by employing ethyl alcohol in moderate proportion with the methyl alcohol. Mr Rheinberg suggested applications of such solvents, for example, in simplifying the technique of the wet-collodion process.

On the proposition of the chairman a very cordial vote of thanks was accorded to him.

In the absence of Mr. F. C. Toy, who was to have read a paper but was prevented by illness from being present, Mr. B. V. Storr, with the assistance of Mr. H. Flower, gave a demonstration of development in bright light by means of the pheno-safranine desensitising process described by Mr. Raymond E. Crowther in last week's issue of the "B.J." Mr. Storr briefly reviewed the experiments of Dr. Luppo-Cramer, and traced the use of dyes of the safranine class from the observation that the oxidation products of certain developers were active in desensitising a plate. The action of the pheno-safranine was undoubtedly a desensitising and not a screening one, since the dye could be used as a preliminary bath which was applied for a minute or so, after which the plate could be developed in a bright light, such as that of a yellow safe light a candle a few feet away, or the ordinary electric illumination of a room—according to the character of the original emulsion. Mr. Storr thought the preliminary bath method was a better one than the addition of dye to the developer, since at certain concentrations there might be precipitation of the dye by the alkali of the developer. A dye solution of 1 : 10,000 was strong enough for ordinary special rapid plates; 1 : 5 000 was recommended for panchromatic plates. His provisional measurements of the reduction in sensitiveness by the use of the bath were that an ordinary plate became of 1/600th of its original sensitiveness, whilst a panchromatic was reduced in sensitiveness only to about half this degree. Mr Storr and Mr. Flower successfully developed a number of plates, both ordinary and panchromatic, in full light, and it was announced that a suitable dye for the process is shortly to be placed upon the market by Messrs. Ilford, Ltd. Some samples were distributed to members.

Votes of thanks to the demonstrators brought a very interesting fixture to an end.

CROYDON CAMERA CLUB.

ALTHOUGH a new acquaintance to the majority, an old friend to many turned up last week in the virile person of Mr. H. W. Bennett, F.R.P.S., who has been somewhat out of the limelight in recent years. Perhaps he is best known as the redoubtable champion of control in development; in these times rather the *rôle* of a heroic Horatius Cocles, for the bridge has to be defended against ever-increasing hordes of time-servers. However, the battle cannot be said to be actually won or lost by either side, though the contest is shorn of its ancient fire and fury. Excellent negatives are produced by both systems, even that hopelessly unscientific pyro-ammonia developer, favoured by many of the best workers in the past, rendering splendid prints when plates responded more kindly to the volatile and, as claimed by some, versatile alkali.

Mr Bennett is also known as a skilful architectural photographer, and is also possessed of a pretty habit of evolving formulæ of utility. Apropos of formulæ—the younger generation of photographers may fail to realise the magic attendant on photo-prescriptions in the past, and how carefully choice specimens were safeguarded, even to the extent of placing misleading labels on bottles containing the solutions. One pictorialist and highly-respected

journalist (no connection with the "B. J."), if memory serves aright, used to compound his pet developer for bromide prints from three bottles, respectively labelled A, B, and hypo. Privileged persons who were admitted to his dark-room during operations, and subsequently did some Sherlock Holmes' business on the clues afforded, spoilt a considerable quantity of paper.

"The Toning of Bromide Prints" furnished Mr. Bennett's theme on this occasion, and capitally he dealt with an ever-interesting subject. A large number of very excellent prints, toned various shades, from an "engraving" black to a warm sepia, illustrated the lecture. Emphatically he denounced the doctrine of fitting the printing process to the negative, which was on a par with the dictum of "Smith (Minor)" that "the horse is a noble animal, but if unkindly treated he ceases to do so."

The so-called "platino-matt" bromide papers were regarded by him as a very poor imitation of platinotype, and he invariably employed an "ordinary" (semi-matt) brand, Wellington's "cream crayon," in fact. Since the war he had found it gave warmer sepias, and this had necessitated a slight variation in his formula for securing varied tones. To obtain the finest quality it was essential that the prints be dried first.

Personally, he was a keen opponent of mechanical procedures in photography, the development of bromide prints excepted. Here correct exposure and full development for a fixed time was compulsory for best results. Also, fresh developer for each print should be employed. This might sound expensive, but was not so, as with a little practice 2 oz. of developer was sufficient for a 12 × 10 print, and even ½ oz. for a quarter-plate. Most of his prints had been developed with Johnson's amidol (equal to the German product in every respect), and he invariably used an acid fixing bath—one ounce of potass metabisulphite to the pound of hypo.

His bleaching bath is composed of the two following stock solutions :—

A.—Potass ferricyanide	1 oz.
Potass bromide	1½ oz.
Water to make	9 ozs.
B.—Mercuric chloride	60 grs.
Potass bromide	60 grs.
Water to make	5 ozs.

Sulphiding Solution.

Pure sodium sulphide	1 oz.
Boiling water to make	9 ozs.

To prepare the sulphiding solution : Take a mineral-water bottle with rubber-sealed stopper; mark to indicate 9-oz. level; warm bottle gradually; insert sulphide and pour on boiling water. Insert stopper and shake till sulphide dissolved, removing stopper now and then to allow steam to escape. When solution has cooled, filter and restore to bottle.

For a warm sepia or brown tone, take 40 to 60 minims of A to every ounce of water. Colder tones are given by varying the proportions of B to A, as follows :—

A.	B.	Tone.
40 Minims.	20 Minims.	Cool sepia.
30 ,,	30 ,,	Colder sepia.
30 ,,	50 ,,	Brown-black.
30 ,,	90 ,,	Engraving black.

As the tone gets colder less exposure is required. Assuming 10 seconds to be right, employing A solution only, then exposures in the above table will be 9, 8, 7, and 6 seconds respectively.

As pointed out by the late Mr. Haddon, he said, whenever a mercuric salt is brought into contact with gelatine, a weak mineral acid bath should follow. Therefore, rinse the prints and pass them through three one per cent. baths of hydrochloric acid (1 dram to 12 ozs. approx.) and wash for ten minutes before sulphiding.

The lecture was followed by a lively discussion, mainly on Mr. Bennett's apparent belief in the almost absolute permanency of *properly treated* bromide prints, especially sulphided ones. Short of destroying the support, he doubted if the latter could be reduced. Obviously, he has never tried acid-permanganate, to mention one reducer, which will clean up the image to the vanishing point. This, by the way, has no direct bearing on permanency, acid-permanganate not being a constituent of the air in terrestial climes. A most hearty vote of thanks was accorded for a really first-class technical evening of the "blooming practical" order, and many expressed a wish to see the lecturer again in the near future. He certainly can make an evening go with a swing.

News and Notes.

Hampshire House Photographic Society.—There will be two open classes, one for prints and the other for lantern slides and transparencies, at the exhibition of the Hammersmith Society, to be held at Hampshire House, Hog Lane, London, W.6, from April 21 to May 19. Mr. F. J. Mortimer will act as judge. Prospectus and entry form from the hon. sec., Mr. C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

Hackney Photographic Society.—The annual exhibition will be held in the Town Hall, Hackney, from March 16 to 19. In addition to a number of members' classes, there is an open class for prints of any subject in which silver and bronze medals will be placed at the disposal of the judge, Mr. G. C. Weston. The last day for the receipt of entries is Saturday, March 12. Prospectus and entry form may be obtained on application to the hon. sec., Mr. Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

Correction.—Mr. F. J. Mortimer points out to us that the reference last week to Mr. Blacklock as secretary of the London Salon of Photography needs to be corrected. Mr. Mortimer has been honorary secretary of the London Salon for a number of years past; Mr. Blacklock was employed in a secretarial capacity in the years mentioned in our notice of last week.

Edinburgh Photographic Society.—The forthcoming exhibition will be divided into three sections :—I., Landscapes, seascapes and kindred subjects; II., portraiture and figure studies; and III., lantern slides. In the two former classes the judges will be Messrs. Henry W. Kerr, R.S.A., R. Burns, and J. Campbell Harper. The exhibition will be held from February 19 to March 5 in the Society's Hall, 38, Castle Street, Edinburgh, from which address the prospectus and entry form may be obtained. The latest day for delivery of pictures is February 10.

One-Minute Photography.—A booklet reaches us from the Magna Plate Company, 2 and 47, East Borough, Scarborough, containing particulars of the cameras for outdoor one-minute direct portraits on cards and buttons. The Magna Company supplies several sizes of camera for this business, and also the requisite sensitive cards and buttons. Moreover, it is ready to supply formula for the making of the emulsion, either gelatine or collodion. The booklet is more than a catalogue, for it contains formulæ for the combined developing and fixing solutions required in this branch of work, and also notes on the making of these portraits by flash-light. It is within our own experience that the information contained in it is of a kind which is very widely sought, and we have no doubt that there will be many applications for the booklet, which is issued price 6d.

Submarine Photography from Aeroplanes.—Writing in the "Geographical Review" on the subject of aerial photography as an aid to geography, Mr. Willis T. Lee, of the U.S. Geological Survey, deals at length with the application of this process to photographing and mapping submarine features. The visibility of objects at great depths in clear water from a point far above the surface has been a well-known phenomenon since the wartime period of "sub" chasing by aeroplane. It is said that objects 45 feet under water have been successfully photographed, and that with the proper plates and light-filters the presence of submerged objects invisible to the eye is revealed by the camera. It has been found possible to use this method of observation to some extent in detecting and mapping sand bars, shoals, drowned terraces and channels. Mr. Lee presents several photographs illustrating the results of the method. Not all photographs of coast lines reveal these subaqueous features. Certain conditions of the atmosphere and the water seem to be necessary for photographing them. "In studying the underwater features as shown in photographs," says

the writer, "caution and careful checking in every possible way are necessary. Changes in hue in the photograph might be due to sediment in suspension rather than to differences in depth of water."

Correspondence.

THE POSITION OF PHOTOGRAPHIC SOCIETIES.

To the Editors.

Gentlemen,—The letter from "Fuller Hope" in your issue of the 31st ult. gave us rather a shock. We had no idea that photographic society life was in such a grave condition. Young and inexperienced as we are, we are moved to contribute our view of the situation, in the hope that it may be of use to any of the "moribund" societies who may be roused to struggle for a livelier existence.

We would advance the following as proof that the photographic public still needs us, despite the "general simplification of photography." In a recent trade competition there were about 23,000 entries, and, writing recently about the work of the judges, the Editor of "The Amateur Photographer" said: ". . . the first selection left over 100 prints in some of the classes. . . The first selection is necessarily the easiest. . ." We believe there were eleven classes in that particular competition, so about half the prints entered were bad enough to be ruled out in the first selection. So there are upwards of 10,000 camera users about who aspire to win prizes, but lack the technical knowledge which might push their prints past the judges' first selections. Some of them may belong to societies, but if London suburban societies with membership rolls of 100-150 cannot muster more than a dozen to a meeting, and the position is as bad in the provinces, it seems a safe deduction that the said aspirants do not attend meetings. The gallant few who sustain the spark of life in these decaying institutions must be old hands. The inference is obvious—the recruits to amateur photography cannot digest the fare provided. If methods of management are being used which were successful before the war, and years before that, one can cease to wonder. The youth of England might commence the study of English with the works of George Meredith, with equally good results.

Whatever may be the case elsewhere, in photography the war has left us in a new world, and we must produce arrangements which will fit its conditions. If we are honestly to work for the advancement of amateur photography we must open our doors with no half-hearted welcome to the army of "beginners." As little strangers in the photographic family they must have first and chief consideration. Numbers of them will never rise above "button pushing," but we must endeavour to make things so easy and pleasant for them that the maximum and not the minimum number will so rise. Under present conditions large membership is a necessity, and we can only look to present-day beginners to make good the ravages of time in our ranks.

We had a large increase to our membership when we announced our intention of catering specially for less advanced workers. That was in September last, and although we have not yet secured 100 members, we have succeeded in keeping those we have interested in our meetings—our average attendance is about 50 per cent. of our membership. We have had a room adapted for enlarging and general dark-room work, and are starting the year with a short series of lessons in enlarging. After that our members will have the use of the room, and as much assistance and advice from more advanced workers as they care to ask for. We are shaping our whole policy on these lines, and may say that Chelsea's plan of members' evenings, praised by "Fuller Hope," appears to us much more likely to hold a society together than a long series of lantern and other lectures of that sort. Of course, the advanced members must also be provided for, but really they want very little holding together as compared with present-day beginners.

We must apologise for the length of this letter, but, as coming from a society unhampered by pre-war traditions, we thought it might be of value.—Yours faithfully,

THE CATFORD CAMERA CLUB,
F. COLEMAN, Hon. Sec.

St. Lawrence Parish Hall, Holbeach Road, Catford.

CHARGES FOR COPYRIGHT REPRODUCTION.

To the Editors.

Gentlemen,—In your issue of December 24 it is erroneously stated that on November 23 the Committees appointed by this Association and the Professional Photographers' Association agreed upon a new scale of charges, which you reproduce. The arrangement was that the scale should be submitted by the Committees to their respective Councils for consideration. My Council decided to decline the proposed terms, so that no agreement has been concluded. Will you please insert this correction and oblige.—Yours faithfully,

E. O. NORTON, Secretary,
Weekly Newspaper & Periodical Proprietors' Association, Limited.

5 Bouverie Street, Fleet Street, London, E.C.4.
January 5, 1920.

TWO OR THREE DIMENSIONS: IDEALS IN PORTRAITURE.

To the Editors.

Gentlemen,—Having been very busy, I have only just come across the letter in the "B.J." for December 24 by Mr. F. C. Tilney. I have not time for correspondence of this sort, but I cannot let pass the inconsistency of Mr. Tilney's remarks. He does not appear to have looked at my paper as a whole, and has missed my object in quoting Mr. Konnody's criticism. He also seems limited in his ideas when he asks, "How is it possible to look at a photograph and forget that it is flat?"

My point is that many painters and photographers try, and successfully try, to get over the flat surface and imitate a rendering in the round, the province of the sculptor. Mr. Tilney says it is on record that Philip IV. momentarily mistook "The Admiral" of Velazquez for the man himself. Does Mr. Tilney wish to drag Velasquez's art to the level of photography as practised by himself? If Mr. Tilney had reflected, I think he would not have quoted this record to bolster up his argument. It was a far bigger thing than a "similation of reality" that led Philip IV. into his mistake.

Mr. Tilney mentions Rembrandt and Turner. I wonder if he has heard of Puvis de Chavannes?

Mr. Tilney may not agree with the value placed on the work of El Greco, and he is quite entitled to his opinion, but why introduce a lot of extraneous matter and accuse me of so much that I did not say, because he is not able to understand what I did say?

In closing, I might say that Mr. Konnody's peculiar form of mental aberration seems to be shared by quite a number of cultivated people.—Yours faithfully, EDWARD DRUMMOND YOUNG.

QUINONE BLEACHERS.

To the Editors.

Gentlemen,—I observe that in the article in your current number dealing with the conversion of silver images into bromide or chloride, MM. Lumière and Seyewetz state that the use for this purpose of benzoquinone in conjunction with hydrochloric or hydrobromic acid has not previously been pointed out.

May I remind you that in your issue of November 5, 1915, you published a communication from me in which I dealt with this particular method at some length, and directed attention to certain practical advantages offered by it. You summarised this on page 383 of the "Almanac" for 1917.—Yours truly, JOHN GOULDING.

Wellington Road, Bridlington.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

B. A.—There is not very much to choose between the 3½ by 2½ and the 4¼ by 3¼, but we think the better choice for anyone who is a careful worker in the way of focussing and development is the 3½ by 2½. The lesser size of plate makes a very considerable difference in the bulk and weight of the camera, and if enlargements are made the results are practically as good.

T. and Co.—The "Journal of the Optical Society of America" is of comparatively recent establishment, and we have not the name of its publishers, or even the address of the headquarters of the society. But we have no doubt that the periodical can be supplied by Messrs. Williams and Norgate, 14, Henrietta Street, Covent Garden, London, W.C.2, who are agents for many scientific periodicals published in the United States.

H. S.—Exposures of one-tenth of a second, such as are given in ordinary cinematograph working, are easily within the capacity of negative cinematograph film exposed in thoroughly good light at *f*/22, and, therefore, the good definition you have seen may be due to stopping down for the sake of depth, although we think the fineness of definition given by the lens at a larger aperture enters considerably into the question, as does also the development of the film.

W. A.—(1) Yes, certainly, by burning a length of ribbon on each side of the lens. It doesn't matter whether the pieces are burnt at the same time, or one after the other. (2) A glossy surface paper should be used, or at any rate one of the semi-matt variety. (3) Yes, use semi-matt, many makes of which will allow of all necessary working-up. (4) We don't think our estimate of value is worth anything, but, say, £2 to £2 10s. We should think the set is worth little more than the selling price of the lens.

M. E.—We don't think there is any hard and fast rule. We understand that the bride is supposed to come out of the church holding the left arm of the bridegroom, and, therefore, it might very well be argued that she should appear in this position in photographs taken after the ceremony. Still less is there any rule for the arrangement of the relatives of the bride and bridegroom. We certainly do not think that it is customary to divide them into two lots on the ground of the respective relationship.

W. W.—Probably the lens is one of the ordinary types of rapid rectilinear as fitted to the cheaper descriptions of camera. There is probably nothing special about it as regards its optical performance. No doubt it can be used at the larger unmarked aperture, if there is no objection to the sacrifice of a certain amount of definition in the margins of the plate. The best method of cleaning the lens is to wipe it gently with very old cotton fabric, such as an old handkerchief, if necessary moistening with a little spirits of wine.

M. W.—So far as our knowledge goes the only country on your list in which there are notable women photographers is America, where a few women, such as Mrs. Gertrude Kasebier, Miss Mathilde Weil, Miss Helen M. Murdoch, and others, have from time to time shown work at the exhibitions of the Salon or the Royal Photographic Society. So far as we know there are no specimens of their work available in this country, and the only means, and that not a very reliable one, of ascertaining their addresses, is by looking up the catalogues of the Salon or the Royal.

S. A.—You can get a faster sensitising preparation, namely, that formerly in use for the so-called "Solar" enlargements, but the coating is by no means as rapid as bromide paper, and requires fairly long exposure by artificial light, whilst the results are far inferior in gradation to the print-out method. We think your best plan for artificial light printing would be to use a transfer method, preferably the Kerotype, materials of which are obtainable from Marion and Co. The results in the way of transfer of the image to silk, satin, etc., by this process are exceedingly pleasing.

A. W.—Under the 1911 Copyright Act it is not necessary to do anything in order to obtain copyright. Copyright is held to be automatically created by the production of the work, that is to say, presuming that the work has literary or artistic merit. The question, however, of the ownership of the copyright at its first creation is another matter. In this respect the 1911 Act is practically on all fours with the preceding Act as regards photographs or drawings, that is to say, if you do the work "on your own" the copyright is your property, whereas if you do it to the order of some other person and are paid or ought to be paid by him, then the copyright is the property of that other person.

N. E.—The customer has a right to have even the first proofs copied if he so wishes since the copyright in the work which he has ordered is his property. But if he does that he thereby, in the clearest manner, renders himself liable to you for payment for the work of taking the negatives, these latter remaining in your custody. In view of the rather sharp method which he has adopted, we do not think that one guinea per negative is an out-of-the-way charge, and we certainly think that if you sue him in the County Court for this amount you will readily recover it. You have the very powerful argument that he thought it worth while to have your photographs copied, but not worth while to pay for them.

W. A. W.—(1) Cameras for such small size of plate are difficult to find among the cheaper models. There were one or two imported from Germany before the war, but we cannot find anything answering to your description on the market at the present time. Moreover, we think makers are quite right in holding aloof from such small, and at the same time, cheap types of camera, for, if you will take our advice, you will choose either a box form of camera, or else one of the more expensive models, say second-hand. Unless the back and front of a folding camera of this small size are absolutely rigid and keep in correct alignment the results will be most disappointing, and that is why the available models are either of the solid metal box form, such as the "Verascope" or "Blocknote," or, if folding, somewhat expensive. (2) We confess we have never seen anything of the kind you describe, but we should think the effect must be produced by outlining the parts of the subject with a varnish, which dries with a gloss, such as ordinary "church" varnish. If you could obtain a specimen of the result and send it to the Vanguard Manufacturing Company, Maidenhead, no doubt they could supply a varnish suitable for the purpose.

JOURNAL OF PHOTOGRAPHY.

No. 3168. Vol. LXVIII. FRIDAY, JANUARY 21, 1921. Price Fourpence.

Contents.

SUMMARY.

The recent paper by Mr. F. F. Renwick before the Royal Photographic Society describes the remarkable action of a solution containing iodide upon an exposed plate, and its application to development in full light; also the colour-sensitising action of a solution of iodide or cyanide. (P. 34.)

Mr. J. I. Crabtree, of the Eastman Research Laboratory, has worked out a process of producing reversed dye images, based on the observation that a tinted film is bleached in an acid fixing bath in those parts of the film occupied by the silver image, which latter can afterwards be removed with a mixture, such as Farmer's reducer. (P. 32.)

Dr. B. T. J. Glover and Mr. E. A. Bierman discuss the question of factorial development, the one in relation to error in outdoor exposures, and the other, particularly, in reference to the strength of the developer. (P. 41.)

In a short contributed article "Thermit" speculates on the possibilities of home cinematography. (P. 31.)

In a leading article we give some hints on the considerations which determine the fixing of the cost of outside or commercial work, and consequently the price to be charged to the customer. (P. 30.)

From the legal standpoint a photograph upon which the owner, in the case of its loss or damage, may set a great sentimental value, is to be valued at the cost of producing it or replacing it. This view of the matter appears to be common to this country and the United States. (P. 29.)

The ultra-artistic window display is not always effective in the commercial sense. (P. 30.)

In the absence of a panoramic camera, long narrow views may be readily obtained by making two exposures on a somewhat square plate by means of a mask. (P. 30.)

A correspondent, "Comfort," confirms in emphatic terms from his own experience our recent recommendation of closed combustion stoves burning anthracite. (P. 40.)

Some practical hints on the advisable features of printing boxes for development papers are given in "Rajar Trade Notes." (P. 35.)

Among other practical hints given by Mr. B. T. Rose at the Croydon Camera Club, were some on matt grinding of glass, sharpening of knives, and making of strawboard boxes. (P. 40.)

Methods of stereoscopic cinematography and drawing by projection and the construction of a lens for forming highly minute images are the subjects of recent patent specifications. (P. 37.)

For the mounting of prints in albums, the dry-mounting process, by means of a press or a hot iron, possesses many advantages over the use of mountants containing water. (P. 30.)

EX CATHEDRA.

Photography in the Sixties. It must be somewhat surprising to a newcomer in photography, who happens to turn over the pages of one of the manuals of about the middle period of the last century, to observe how familiar are many of the drawings of apparatus even to his modern eye. The "Practical Photography," issued in 1863 by the Fleet Street firm of Bland & Co., a copy of which has come into our hands by the courtesy of Messrs. Holmes Brothers (London), Ltd., affords an instance of how very little progress there has been in the design of some of the staple appliances used by the photographer. The Kinnear folding camera, which was certainly a great innovation at the time, differs simply in detail from the most approved light-model cameras of the present day; the studio camera stand is even more akin to the apparatus to be found under every skylight, and repeating backs, vignetting glasses and view finders might almost represent the current stock of a photographic dealer. But one has to turn to the text, which is a manual of practice, in order to realise the difficulties of those who used either the wet-collodion or dry-collodion process, particularly in the Tropics, when the operations of development, etc., had to be done in an unventilated tent of a few cubic feet capacity at a temperature of over 100 degrees. Even in these practical matters the old manuals have their hints of present-day value, for example, that of Dr. Hill Norris, for the packing of his dry-plates in gutta-percha or other waterproof wrapping and enclosure in a boxful of bran.

* * *

The Value of Photographs. Our contemporary, "Studio Light," winds up the series of chapters which it has published on legal aspects of professional photography, particularly in reference to copyright and ownership of the negative, by a few notes in its current issue on the value which can be put upon photographs which have been lost or damaged. A photographer occasionally finds himself in an awkward situation through some photograph, entrusted to him by a customer, being lost in his own establishment or possibly in that of an enlarger or trade printer to whom he had sent it. In the United States, as in this country, the sentimental value which is attached by the owner to a photograph is not generally accepted in a court of law as a basis for the monetary compensation which the owner shall receive. Broadly, it may be said that its value will be appraised as the cost either of making it in the original instance or replacing it at the present time. Apparently, cases involving this question have been of rare occurrence in America, for "Studio Light" cites only one, and even in that the essential issue was side-tracked, although the court disclosed its opinion that, in the case of an undeveloped film which had a highly sentimental interest, no damage could be recovered above the value of the film in the

ordinary way of trade. On the other hand, when a dispute of this kind comes into a County Court, a good deal of casuistry can be employed by way of enhancing the value of the photograph which has been lost or damaged. It will be argued, on behalf of the owner, that some wretched collodion positive cost guineas to make or, on the other hand, can only be adequately replaced by a modern miniature; the lesson of all which is that though the photographer is in a pretty good position to resist ridiculous claims, the glorious uncertainty of the law makes it desirable to come to a reasonable agreement with the customer if that is possible.

* * *

Mounting in Albums. If the specialty be properly pushed, dealers and photographers can find some remunerative work in making up albums of amateurs' prints, either contact or enlarged. The dry-mounting process has in a way rendered this work much easier, since it is now possible to make the album close neatly when filled, which was difficult when wet mounting was the rule. There are, however, a few points to be observed. If the job is a high-class one, it is better to mount the prints on separate cards before binding, as this affords an opportunity to replace any which may have come to grief. This advantage is also possessed by the loose-leaf albums, the only drawback with these being their less finished appearance. When using ready-made albums it will often be found advantageous to use a flat iron instead of the hot press. With a really good tissue and a thinnish bromide paper the flat iron answers very well, and all risk of damaging the binding in the press is avoided. It is as well to remember that the quality of the card or paper leaves has much to do with ease of working; one sample which we have handled absorbed the shellac and thus prevented adhesion.

* * *

Window Displays. The window or show-case is often the only advertising medium used by a photographer, and it is essential that he gets the last ounce of "pulling" power out of it. To this end he should consider not his own artistic aspirations but the taste of the public in his locality. Moreover, if he is situated in a parade of shops he should to some extent conform to the general style of display. We are moved to make these remarks through observing two windows in a busy shopping centre. The one was fitted in waxed oak and dark cloth with a few excellent specimens, and the artificial lighting was subdued. No one stopped to look. It was a dull spot in a bright parade and was quickly passed by. Near it was the show of another firm professedly doing a cheaper class of business, although for the same quality of work the prices were practically the same as those of the other studio. This window was brilliantly lighted, the fittings were light in colour, and there was abundance of gilding. Here, hardly a moment elapsed without someone inspecting the window. This should be suggestive to those who find that the "art" style of display does not bring as much business as they can do with.

* * *

Panoramic Groups. Although the demand for this special kind of group photograph has declined with the demobilisation of the great army, most photographers have at some time or other to take groups which are long and narrow in shape. While a camera of the Cirkut or the older Al Vista types is the best for the purpose, quite passable results may be obtained upon the half (lengthways) of an ordinary large plate. With a 15 x 12 camera two exposures, each 15 x 6, may be made upon the same plate, by using a sliding mask. As distant a point of view as possible should be chosen, so as to utilise a lens of as great a focal length as will include the whole subject. This minimises the broadening of the faces near the margins. If the lens is of the rectilinear type the group should be arranged in a curve, but not so deep a one as is required by the Cirkut. In order to equalise the illumination a rather small aperture, say *f*/22, or in good light *f*/32, should be used and a full exposure given. With a 400 H and D plate one second at *f*/22 should be ample in fair daylight at this time of year.

COSTING FOR OUTSIDE AND COMMERCIAL WORK.

In every well-organised manufacturing concern there is in operation some system of ascertaining the cost of each job which is executed, so that a fairly correct idea can be obtained as to the profit which has been made upon it, if a previous estimate has been given or that a fair and remunerative price can be fixed if no such contract has been entered into. In only a few cases do we know of this being done by photographers, and only then by trade and commercial houses as distinguished from the all-round worker. The consequence is that very much work is done, if not at an out-of-pocket loss, at such a small profit that it is hardly worth touching. On the other hand, those whose business is mainly portraiture are apt to make charges which, although quite justifiable for artistic work, are too high to encourage those who require photographs for trade purposes to use them as freely as they would do if they could be obtained at a commercial price.

Much unpleasantness with customers may be avoided by having an agreement, in writing, if possible, as to the price of any job before it is commenced, although it is difficult to arrive at the happy medium which will be agreeable to both parties without a fair experience in this class of work. We offer the following hints on the various factors which have to be considered in estimating, and although, at the beginning, there may have to be a certain amount of guess work, a nearer approximation is made by guessing at certain details than by guessing at the cost in a lump.

Usually, photographers in a moderate way of business forget that besides being workmen they are traders, and if they get a moderate percentage over out-of-pocket expenses, consider it as profit when it is really wages and poor wages at that. It is necessary, therefore, to include one's own wages as a part of the cost before reckoning on gross profit, and to remember that out of gross profits have to be taken what are known in business circles as "overhead or standing charges," which include such items as rent, rates, lighting, cleaning, repairs, and redecorations, renewals of apparatus, packing and postages, stationery and the like.

The first item which will occur to most is that of materials—plates, paper, mounts and chemicals. These should be taken at list prices, the trade discounts being considered as covering waste. Next comes labour. This must be calculated upon the time actually taken upon the job, whether the work be done by the principal or by an employee, remembering that there is a certain amount of unused time to be covered under this head. Thus, if a man's wages for the week work out at two shillings per hour, it is necessary to estimate them at, say, half-a-crown to cover such periods as cannot be allotted to any order in particular. The wages of operator, printer, mounters and spotters must, of course, all be

treated in this way, and time occupied in travelling to and from outdoor jobs reckoned as actual work.

Tips, railway and cab fares, and any incidental expenses must also be added before we can consider the out-of-pocket costs as covered. Then comes the question of profit. Bearing in mind the two facts that overhead costs have to be met and that no trade discounts have to be allowed to the customer, it is fair to double the net cost; that is to say, to charge a pound for every ten shillings of the estimated cost.

This may appear an extravagant charge to some photographers of our acquaintance, and in their cases it would be so, for no care is taken to see that work is produced upon an economical basis. In many establishments a great deal of time and material is wasted, and it would be manifestly unfair to ask a customer to pay for this, plus 100 per cent. A systematic method must be adopted by the commercial photographer who is to build up a satisfactory business, and the portrait photographer will find it profitable to follow the same course, if he wishes to know what his prints cost him. Time and money spent in book-keeping are not wasted, even in a small business. If, for example, a stock account is kept, in which all plates and paper are entered as purchased, and a balance struck periodically between the number of plates purchased and the number of negatives finished, the paper used and the prints delivered, it is interesting reading. It would prevent the occurrence of such a case as once came under our notice, where an operator gained a reputation for good work by making about ten exposures on each sitter and selecting the best three for proofing.

It is the moral duty of the photographer to have all his apparatus and appliances ready for instant use. If he has to start on an outdoor job the only preparation necessary should be to fill his slides and, if necessary, to back his plates. If he goes in for catalogue work his special backgrounds, shades and supports should be ready to hand, so that he can start on his job without loss of time.

In the case of reprints from previous orders or from customers' own negatives it is safe to take as a minimum the prices quoted by a first-class trade firm, plus fifty per cent. It may sometimes pay to put such work out, and on this basis it can be done at a reasonable profit.

Amateur work hardly comes within the scope of this article, but we may give one word of advice. It is, to accept no work at less than the Kodak company's current rates. To attempt to compete with the chemists' sweated prices is futile, and such work is best declined. If it is pointed out that the work will be more skilfully done, and that a choice of printing methods is available, orders for better styles are often to be obtained.

There might be difficulties in the way, but it might be a benefit to the profession if the P.P.A. could formulate a *minimum* scale of charges for various classes of work, excluding portraiture, and circulate it privately among its members. Many photographers are sadly in need of some guidance in this direction, and quote hopelessly low prices, because they know no better, to the detriment, not only of their fellows, but of themselves. There are, of course, always outsiders who will cut prices as long as they can get credit for supplies for which they do not mean to pay, but these are a small body and need not be considered seriously.

SOME THOUGHTS ON HOME CINEMATOGRAPHY AND ITS POSSIBILITIES.

I was recently interviewed by a gentleman interested in home cinematography, and I am given to think that the line demands some attention from professionals. It is an innovation, and innovations are necessary from time to time to galvanise new life into business and to enable us to move with the times.

But new ideas and business stunts are not guaranteed winners from the start, and some thinking is wanted if we are to derive all possible benefit from a policy of being up-to-date. I have come to a few conclusions on the "potentials" of home cinematography (hereinafter referred to as H.C.), and though they may or may not prove sound, they will I think serve as a basis for deeper consideration by any professional interested.

The professional's interest will depend largely on the class of customer he caters for. If his clientèle is of the well-to-do variety, H.C. may prove a big thing for him, but for the man whose maximum prices are in shillings there is no very obvious probability of success. Given the right class of customer the question arises—what is the best way to offer the line to the public, seeing that the photographs themselves are of no use without a projector? Shall lengths of film be taken, printed and demonstrated, with the intention of selling the necessary projectors on the strength of the exhibitions, or shall the sale of projectors be concentrated on first? The first mentioned would seem to be the more promising way, but it presents something of a problem with regard to pricing. Obviously, the photography cannot be done at a nominal price unless the sale of a projector is a foregone conclusion, and given the foregone conclusion, which implies satisfaction with the film on the customer's part, there should be no need of a low price. On the other hand, can a high price be charged when a customer does not enthuse over the result and is not inclined to buy a projector, in which case the film is useless? I do not say that an equitable scale cannot be worked out, but it will require some thought.

Some types of sitters will, I think, take more kindly (and profitably) to H.C. than others. Children should prove the best sitters of all, for they are—even the clumsy ones—more natural than the average grown-up, and with the "keep-still" bogey absent make splendid subjects for photography. Another thing, living child studies will not be criticised by the persons they portray, and, consequently, will have a smaller chance of hostile receptions than that which unposed and unretouched work of adults is subject to at sitters' hands.

Next to children, I would expect elderly people to rank, particularly if the photographer will take the pictures in the sitter's own home. I can see grown-up sons and daughters in raptures over "that last one of pa driving his Ford-Royce" (or in his library or among his expripedia), and pictures of mother in her own domicile, though perhaps nearer to still-life portraits than actual "motion" pictures, will be greatly appreciated.

But as far as true portraiture goes I am not so optimistic with regard to the young grown-ups. If a portrait of a young lady—or a young man—is going to please its original, it must be at least a little idealised. This is done by lighting, posing and retouching. Now we can light a moving portrait with as great and even greater chances of idealism, and when in motion the absence of retouching is not quite so conspicuous, but how are we to pose a moving figure? Cinema actors may study deportment, and if they don't any awkward clumsiness they show is not going to damage the photographer, but this does

not apply to the public. To say that ungraceful or inartistic movements are all right because they are true to life will not do at all. One cannot take an unretouched "study" of a damsel sitting like a collapsed sack of flour and say it is all right, no matter how true to life and character it happens to be.

But even if my cynical views are borne out, the young grown-ups will still prove useful. Who is going to enthuse over projectors? If the young men don't I shall be surprised. And who is going to provide subjects for lively *genre* pictures where art and elegance in deportment are decidedly not wanted? The young men and women every time, and the wide-awake photographer who tries H.C. should not forget that there are such things as tennis racquets and motor bikes.

In concluding these speculative remarks, I might point out that they are possibly not in accordance with the views of manufacturers and others who have gone much deeper into the subject; but they do not pretend to be authoritative, and my only object in voicing them is to assist photographers' interest in the moving times.

THERMIT.

A METHOD OF PRODUCING REVERSED DYE IMAGES.

(Communication No. 97 from the Research Laboratory of the Eastman Kodak Company.)

In the course of a series of experiments on the effect of an acid hypo solution on various dye solutions and samples of tinted motion picture film, it was observed that on immersing certain samples of tinted film in the acid fixing solution, the dye was bleached out in the region of the silver image, while the high-lights remained unaffected; producing a result opposite to that of toning, namely, tinted high-lights and black and white shadows.

The possibilities of utilising the phenomenon in producing dye images were at once realised; and by simply removing the black silver image in a suitable solvent of silver such as Farmer's reducer, after bleaching as above, a reversed dye image was obtained; that is, starting with a positive silver image a negative dye image was obtained.

In the following experiments, images on motion picture film were used, though the methods are applicable to any gelatine silver image.

The effect under consideration was discovered when using methylene blue; but on testing a large number of other dyes it was found that dyes such as methylene green and, in general, dyes which are readily reduced to the leuco base can be used also.

It was found that two methods of procedure are possible as follows:—

1. Bleach the image in a mixture of the dye and bleaching bath; or.
2. First dye or tint the film, and then bleach.

1. The following acid hypo bleaching bath was used in the preliminary experiments:—

Acid Hardener.

Alum	56 gms.
Sodium sulphite	56 gms.
Acetic acid, 28 per cent.	400 c.c.s.
Water to	1 litre.

For use:—

Hypo (25 per cent. solution)	100 vols.
Acid hardener	5 vols.

In order to determine the active bleaching agent in this bath, tests were made with mixtures of dye and the individual ingredients in various combinations, and it was found that hypo in combination with hydrogen ions is the active bleaching agent. Thus, the following mixtures are inactive:—

Hypo + Dye,
Dye + Acid.
Dye + Sodium bisulphite,

while on immersing an image in a mixture of dye+hypo+acetic acid or sodium bisulphite or acid hardener, good results are obtained.

The following bleaching bath was found to give the best results:—

Methylene blue	1 gm.
Hypo	5 gms.
Acid hardener	2.5 c.c.s.
Water to	100 c.c.s.

On immersing a positive image in this solution for three or four minutes, the dye enters the high-lights, while the shadows remain clear, so that on washing and removing the silver image as described below a negative dye image is obtained.

2. By first tinting the film and then bleaching, stronger dye images were obtained as follows:—

Immerse the film for two or three minutes in the following bath, and rinse:—

Methylene blue	1 gm.
Ammonia (concentrated)	0.1 c.c.
Water to	100 c.c.s.

Now bleach in the following acid fixing bath until the shadows are black and free from dye:—

Hypo	5 gms.
Acid hardener	2.5 c.c.s.
Water to	100 c.c.s.

After bleaching wash for about ten minutes in running water and remove the silver image as described below.

When using method 2, if the bleaching is prolonged beyond a certain point, the dye in the high-lights commences to bleach out until, on prolonged bleaching, all the dye disappears. On subsequently removing the silver so as to reverse the image, very peculiar line images are obtained if the bleaching is prolonged beyond the point when all the dye is bleached in the shadows. It is better to bleach in a weaker bath than in a strong one, since this permits of greater latitude in working. With the above formula from one to two minutes is an average bleaching time. Around normal room temperatures (65 to 75 deg. F.) small changes in temperature have very little effect on the rate of bleaching.

After bleaching, the film should be washed about ten minutes in running water and immersed in the following bath of Farmer's reducer:—

Hypo	2.5 gms.
Potassium ferricyanide	1 gm.
Water to	100 c.c.s.

After all the silver is removed, the film should be washed for five or ten minutes and dried.

Other silver solvents such as a solution of iodine in potassium cyanide, iodine in thiourea, potassium ferricyanide, and ammonium thiocyanate can be used in place of the Farmer's reducer.

Theory of the Process.

The action of the bleaching bath is apparently to reduce the dye to the colourless leuco base in the region of the silver image, the leuco base washing out of the gelatine more rapidly than the dye. This leaves a reversed dye image with black silver in the high-lights, so that on removing this silver a reversed dye image is obtained.

The precise action between silver and acid hypo in the presence of methylene blue is difficult to explain. It was at first considered that the reaction between the silver image and the acid hypo is analogous to that between zinc and sodium

bisulphite to produce zinc hydrosulphite and sodium hydrosulphite, as represented by the following equation:—

$$Zn + 2NaHSO_3 + H_2SO_3 = Na_2S_2O_4 + ZnSO_3 + 2H_2O$$

Sodium hydrosulphite + zinc sulphite.

However, it was considered that silver is too noble a metal for the above reaction to occur in the absence of hypo, and this was confirmed by the following experiment:—

Finely divided metallic silver was heated for thirty minutes to boiling with a 25 per cent. solution of sodium bisulphite, to which was added 1 per cent. of acetic acid. On adding a little of the supernatant liquid to a solution of methylene blue, the dye was not decolourised, though on repeating the experiment with the addition of hypo to the acid bisulphite the liquid decolourised the methylene blue at once, thus indicating that a powerful reducing agent was produced. A blank experiment which consisted in heating together hypo and acid bisulphite showed that this mixture alone does not reduce the dye except in presence of silver.

These experiments confirm the practical photographic results, namely, that hypo is necessary for the reaction between the silver and the acid bisulphite to occur. In the case of zinc, the presence of hypo is not necessary.

The exact chemical nature of the substance formed which reduces the dye has not been discovered. During bleaching of the tinted film in acid hypo the silver image turns yellowish brown, and its light-transmitting power is visibly increased. On treating the bleached image with a 30 per cent. hypo solution or 5 per cent. potassium cyanide some of the image is removed, leaving a residual image apparently of silver which is soluble only in silver solvents such as Farmer's reducer.

The above explanation raises the question as to whether any reaction takes place in the ordinary course of fixing out a silver image in an acid fixing bath in the absence of methylene blue. Certainly no visible change in the image occurs at normal temperatures in two or three minutes with no apparent change of colour. Previous experiments have shown that silver dissolves slowly in a solution of hypo in the presence of air (the oxidiser), so that if methylene blue is regarded as the oxidiser the analogy in the case of the oxidation of silver by a mixture of acid hypo and methylene blue is complete.

A number of other bleaching baths can be used in place of the acid hypo, such as an acid solution of stannous chloride, acid amidol, and acid ferrous nitrate.

Several difficulties were met with in producing good dye images as follows:—

1. *Bleeding of the Dye.*—After dyeing in a plain solution of the dye, rinsing and bleaching, it was found that the dye readily washed out; in fact, almost as readily as the leuco base, so that weak dye images were obtained. Attempts were, therefore, made to mordant the dye as follows:—

A. By mordanting after dyeing by means of known mordants for basic dyes such as phosphotungstic acid and tannic acid. After dyeing, the film was given a short immersion in a 1 per cent. solution of phosphotungstic acid (which mordanted the dye almost completely) and then washed for ten minutes. This treatment resulted in patchy images, and it was not easy to subsequently remove the silver image in Farmer's reducer.

B. By mordanting after bleaching and washing and before removing the silver, better results were obtained, though some streaks appeared after removing the silver as above.

C. The best results were obtained by adding ammonia to the dye bath in the first place, which increases the rate of dyeing and retards the rate of bleeding on washing.

2. *Re-oxidation of the Leuco Base.*—The leuco base of methylene blue is readily oxidised back again to the dye by suitable oxidising agents; and under certain conditions with certain bleaching baths and washing in water containing dissolved air, after bleaching and washing the leuco base is oxidised back to the dye so that the film assumes the tinted condition again. The addition of a trace of sodium bisulphite to the wash water tended to retard this oxidation.

Re-oxidation also occurs in the Farmer's reducer if all the leuco base has not been washed out after bleaching, which explains the necessity for thorough washing after bleaching in the acid hypo.

Positive Dye Images.—During washing of the image after bleaching in the Farmer's reducer it was observed that in some instances a positive image was obtained, that is, the leuco base was mordanted to the silver image and was re-oxidised to the dye while the dye in the high-lights washed out, thus producing a positive image from a positive.

The mordant in this case is silver ferrocyanide formed in the Farmer's reducer. A silver image when bleached in a mixture of ferricyanide and a trace of hypo is converted to silver ferrocyanide, which in a finely divided condition is a powerful mordant for basic dyes. If, therefore, after bleaching, the image is only slightly washed the leuco base remains, and on bleaching in the Farmer's reducer is mordanted to the silver ferrocyanide image, and is oxidised to the dye. On prolonged washing the methylene blue is washed out of the high-lights, leaving a positive dye image.

Toning and Tinting.

Interesting effects are obtained by dyeing, bleaching, and washing, and, without removing the silver, immersing in a uranium toning bath or by dye toning the silver in the usual way. The result is that of a toned silver image with the high-lights tinted. This, of course, distinct from the usual toned and tinted effect, where the dye layer covers the entire film.

Line effects are produced by prolonging the bleaching in the acid hypo and subsequently toning the silver image as above. The effect is that of a toned silver image with line lighting and tinted high-lights.

Odd tinted effects are obtained by merely dyeing and bleaching and washing and prolonging the bleaching time a little above the normal.

Summary.

Reversed dye images can be obtained by first dyeing a gelatine silver image in a dye which is capable of being reduced to the leuco base, which is more readily washed out of gelatine than the dye, and after tinting, bleaching in an ordinary acid hypo bath, washing, and subsequently removing the silver image in a solvent of silver such as Farmer's reducer. The excellence of the results depends largely on the correct time of bleaching and on the thoroughness of washing after bleaching. If the washing is not thorough, on immersing in the Farmer's reducer the leuco base is mordanted to the silver ferrocyanide formed, so that on prolonged washing the dye washes out of the high-lights, leaving a positive mordanted dye image.

The author is indebted to Mr. D. S. Mungillo for assistance in carrying out the various experiments.

J. I. Crabtree.

Courses in Technical Optics.—The courses of lectures on technical optics at the Imperial College of Science and Technology during the spring session include a general series by Professor Cheshire, and lectures on optical designing and computing by Professor Conrady, on optical measuring instruments by Mr. L. C. Martin, and on the mechanical design of instruments by Professor Pollard. Laboratory or class work is arranged in conjunction with all these courses of lectures.

British Photographic Research Association.—In "Nature," of January 13, will be found a short article by Dr. T. Slater Price on the work and future programme of the British Photographic Research Association. Dr. Price writes of the immensely wide field of work which is presented by the investigation of the physical and chemical properties of the raw materials and products of the photographic emulsion maker. His notes include a list of the publications of the Association since the time of its formation.

THE ACTION OF SOLUBLE IODIDES ON PHOTOGRAPHIC PLATES.

[The following paper, recently read before the Royal Photographic Society and now published in the Society's journal, continues the very interesting observations by Mr. Renwick on the action of iodides on exposed, undeveloped plates, and presents in, perhaps, more readily assimilable form the process of development in full light of a plate which has been treated with iodide. It also contains the record of observations on the production of red-sensitiveness by mineral salts, which immediately following the reading of the paper, was found to have been noticed in different circumstances by two other investigators, Messrs. Capstaff and Bullock.—EDS. "B.J."]

THE modern dry plate consists of a sheet of glass bearing a film of gelatine in which are embedded countless minute grains of silver bromide. The silver bromide generally contains a small proportion, ranging from 2 to 10 per cent., of silver iodide, forming with it a homogeneous mixture, or, as it is sometimes called, a "solid solution."

Both salts are remarkable for their extremely small solubility in water, silver bromide requiring nearly ten million times, and silver iodide from 500-1,000 million times its weight of water to dissolve it. Silver iodide would probably be incapable of existence were it not for this extraordinary insolubility; it would spontaneously decompose into silver and iodine when dissolved, for the two elements are very weakly held together. Iodine, however, is an element having well-marked polyvalency, and readily unites with other substances containing iodine, as is shown by the ease with which silver iodide dissolves to form double salts AgI.KI and AgI.2KI in strong solutions of sodium or potassium iodide, and the obstinacy with which it retains these salts or even free iodine when brought into contact with their weak solutions. No amount of washing will remove the last traces.

From these remarks it will be evident why silver bromide when bathed in a soluble iodide is rapidly converted into the far less soluble silver iodide, and why, if the iodide solution be strong, the iodide of silver dissolves in it. 100 c.c. of a 30 per cent. solution of potassium iodide will dissolve about 3 grams of silver iodide and stronger solutions a still larger proportion of AgI to KI. Consequently it is not difficult to fix a dry plate in a potassium or sodium iodide solution of 20 per cent. strength.

Apart from its cost, however, such a fixing bath suffers from the serious drawback that it causes softening or even melting of the gelatine film, unless the latter has been well hardened first.

Even in very dilute solutions of soluble iodides the conversion of solid silver bromide to iodide is singularly rapid and complete, provided there is enough solution present. Precipitated silver bromide is completely changed to iodide by excess of a 1: 5,000 solution of potassium iodide, while a 1 per cent. solution will completely convert the silver bromide in a dry plate to iodide in a few minutes at normal temperatures, provided sufficient solution is used to cover the plate well and it is kept moving.

In a lecture delivered last March before the Liverpool Section of the Society of Chemical Industry ("Journ. Soc. Chem. Ind.," Vol. xxxix., No. 12, p. 156r, and "B.J.," lxvii., pp. 447, 463), I described and demonstrated certain experiments concerning the action of soluble iodides on the latent image. It was shown (1) that it is possible to fix an exposed plate in a strong iodide bath, and, after washing out the salts, to develop an image in silver by means of any of the well-known physical developers; and (2) that it is possible to develop an exposed plate in an alkaline amidol solution after the whole of the silver salts in the plate had been converted into iodide. A suitable bath for this purpose is:—

Sodium or potassium iodide	10 gms.
Cryst. sodium sulphite	20 ,,
Sodium or potassium sulphocyanide ...	30 ,,
Water up to	1,000 c.c.s.

With the assistance of my colleague, Mr. Olaf Bloch, the influence of numerous salts and other substances in various proportions was tested in order to discover the composition of a bath which would entail the least loss of image by the treatment. Certain hardening and anti-swelling agents, e.g., formaline sodium acetate, etc., were found useful for counteracting the softening action of the sulphocyanide on the gelatine. An addition of 1 to 2 per cent. of potassium bromide appeared to preserve the delicate half-tones to some extent, as did also 2 per cent. of gum arabic, 10 per cent. of alcohol, or the addition of a drop or two of weak silver nitrate, sufficient to yield a faintly turbid solution, but no great improvement on the simple formula given above was found, provided it is used quite cool (55 deg. to 60 deg. F.).

The sulphocyanide has a marked influence on the subsequent developing process, greater density and detail being obtained when it is used. It undoubtedly modifies the physical character of the silver iodide formed in the process, and its effect is probably related to this fact. The chief use of the other additions mentioned seems to be to slow the reaction; slower conversion to iodide invariably led to more complete preservation of the image. One of the interesting features about these iodised plates is that they are so insensitive to light that they can safely be developed in a strong white light without fogging, except when certain developing agents are employed. The most notable of these exceptions is hydroquinone, which has a well-marked sensitising action on silver iodide, and causes it to fog in a light in which alkaline amidol is a perfectly safe developer. Development of the iodised and well-rinsed plate in an alkaline amidol developer requires a long time to attain completion, but 10 minutes at 65 deg. F. is usually sufficient for a plate which, when used in the ordinary way, would give average density in about four minutes in a normal pyro-soda developer.

The formula we adopted was:—

Amidol	20 grs.
Soda carbonate, cryst.	1 oz.
Soda sulphite, cryst.	1 ,,
Water	10 ozs.

In the course of these experiments the remarkable fact was discovered that similar quantities of sodium thiosulphate (hypo) could be substituted for the sodium or potassium sulphocyanide in the iodising bath with at least equally good results, provided the iodised plate was not exposed to white light before development, but that if, while the iodising solution was still in the film, the plate was exposed to white light, the latent image was to a large extent destroyed. This led me to try the effect of exposing in the camera a plate which had been well exposed to diffused light and then iodised, with the result that it was found possible to obtain direct positives in the camera by this process, which was also described and shown at Liverpool last March. The reversing action of soluble iodides on latent images on AgI in collodion had been known since the time of Poitevin in 1859, but here we have a latent image, formed originally in silver bromide, then transferred to silver iodide and found capable of destruction by light in the presence of soluble iodides, with the additional interesting fact that the latent image is far more sensitive to light if thiosulphates are also present. The same effect is observable in a plain iodide, or iodide and sulphite, solution to a smaller degree, while sulphocyanides appreciably retard the reversing action.

A recent private communication from Dr. Lüppo-Cramer informs me he has since found that after destruction of the original latent image in this way, it is possible, by further very prolonged or intense exposure, to form a new latent

image, a result of considerable interest if not altogether unexpected.

I now come to the most recent outcome of these experiments, and one not hitherto published. Since Lainer's discovery in 1891 of the remarkable effects of minute additions of iodine to alkaline developers, von Hübl, Lüppo-Cramer, and other workers have made a fairly thorough qualitative study of them, both with iodine tincture and alkaline iodides; and Sheppard published a valuable quantitative investigation of the subject so recently as January of this year in our journal ("Phot. Journ.," 1920, p. 12). In that paper he describes and illustrates what he believed to be a fogging effect of very dilute solutions of potassium iodide when applied for a few seconds to the film of an ordinary dry plate. Moreover, he attributes the fog to a nucleus infection of the bromide particles, though of what kind is not very clear.

My observations led me to doubt his explanation, so I repeated his experiments, with the result that I find soluble iodides to have no fogging action whatever, *provided that the plate, both during and after bathing* in the weak iodide solution, *is not exposed to orange or red light.*

Further experiments soon conclusively proved that the effect of these extremely weak iodide solutions (which may be as dilute as 1 part in 50,000) is to render the plate markedly orange and red-sensitive. This may readily be demonstrated by exposing a treated plate, bathed for 15-60 seconds in 1: 20,000 potassium iodide and subsequently washed in water, to the spectrum. To assist in locating the regions of the spectrum an exposure on a panchromatic plate was interpolated between those of the untreated and treated ordinary plates, the lines crossing this spectrum being the green and two yellow lines of the mercury arc, the yellow sodium D line and the lithium line in the red.

So far as I know this is the first recorded instance of colour-sensitiveness being conferred by bathing a plate in a colourless solution. Naturally, the correct explanation of such a curious effect is much to be desired. For the present I prefer to leave this point without discussing its obviously important bearing on the latent image problem.

A fair number of salts have been tried in the hope of discovering others capable of doing the same thing. So far, only one other has been found—namely, a weak solution of sodium or potassium cyanide. In strengths ranging from 1 part in 2,000 and up to 1 :10,000 the effect is exactly similar in character to that obtained with iodides. It seems clear, however, from the similarity of the effects of two such different classes of salts as iodides and cyanides that the conferred red-sensitiveness must be due to a change within the silver bromide or bromide and iodide grains rather than to anything akin to ordinary sensitising by dyestuffs.

There is evidently an immense field still open to those photographers who do not possess the advantages of a well-equipped laboratory in the prosecution of such relatively simple experiments as those described in this paper, and I trust that many photographers may be induced to try for themselves to enlarge the boundaries of our knowledge concerning such remarkable phenomena.

F. F. Renwick, A.C.G.I., F.I.C.

The British Trade Review, in a special January issue, takes a wide survey of British industry in a large number of individual branches of production. Mr. F. G. Kellaway, P.C., M.P., head of the Department of Overseas Trade, contributes an article by way of diagnosis of the present phase of commercial depression, and calls for calculated and far-seeing courage as the remedy. Our contemporary covers a great number of trade fields, its first-hand information regarding which must be of the greatest interest and value to the overseas readers, for whom it specially caters. No doubt many of our foreign subscribers commercially concerned in importation of British goods will be glad to obtain a specimen copy, as they can do by application to 113, Cannon Street, London, E.C.

PRINTING APPARATUS.

From "Rajar Trade Notes."

"Any old box with a light in it will do for bromide printing" was the remark made some years ago by a well-known photographer who had scrapped his printing frames, and his remark is substantially true to-day. An exposing light-box is a *sine qua non* to all photographers, and we offer a few suggestions which may be useful to those who like to make their own printing apparatus.

In designing a printing box we have first to consider the essential points, viz. :—

1.—Sufficiently large to give perfectly even illumination to cover the largest negative likely to be used.

2.—Ample light to enable gaslight and studio development prints to be made, with a provision for screening the light when used for bromides.

3.—A vignette holder, or a diffusing platform, about one inch away from the negative for "faking," or equalising negatives.

4.—Exposing switch that can be worked with the foot.

5.—A pilot light of an amber colour for adjusting the sensitive paper when printing white margins.

The first point is the size of the box, and as a guide we may say that for covering negatives up to 12 ins. by 10 ins. the box should be 18 ins. square and 18 ins. deep, and in order to obtain perfectly even illumination the inside of the box should be white and contain a piece of white cardboard bent to U shape. The opening in the top of this box should be fitted with a piece of plate-glass 13 ins. square, so that 12 ins. x 10 ins. negatives can be printed either way. The necessary diffusion is obtained by the platform mentioned later.

As regards the second point, we think that the best illumination is obtained from three 100 c.p. metal filament lamps, fitted to the bottom of the U reflector, so that the filaments are 12 ins. from the underside of the plate-glass top. This arrangement will enable the printer to get fully exposed gaslight prints from an average negative in from two to eight seconds, and instead of removing some of the lamps when making bromides, we think it better to screen down the full light by using a light cardboard cut-out containing a sheet of thick white paper. This is slid along a small ledge fitted to the sides of the box, and just high enough to clear the tops of the lamps. The front of the box should be hinged about half-way down so that the screen can be inserted or broken lamps replaced.

The vignette can be placed upon a diffusing platform, which is easily made by covering a stout cut-out with grease-proof paper, or dry-mounting tissue. This platform is slid along two other ledges fitted inside the box at about one inch from the plate-glass top. The practical printer will at once see the great utility of this "faking" platform. Pieces of paper can be placed upon it in such a position that will shield dark shadows, or even-up negatives that are uneven in density. Several negatives can be printed at once after being equalised in density by placing pieces of tissue paper on the platform under the thin negatives.

The switch should be arranged so that both hands are free for pressing the paper upon the negative, and we find that a switch worked with the foot is most satisfactory.

The pilot light is useful and should be fitted so that (excepting when exposing) it is always alight. An 8 c.p. carbon filament lamp covered with two thicknesses of orange or amber fabric answers well. For adjusting vignettes, or for faking, it is best to switch on the white light.

The printing box is best fitted under the printing bench, and the plate-glass let in the top of the bench.

There are many excellent printing machines to be obtained which combine a light-box and all the necessary fitments for strip-printing, borders, &c. In choosing ready-made apparatus care must be taken to avoid all fitments that have projecting parts or metal clamps that drag the sensitive paper along and scratch the surface.

B

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Getting More Business by Advertising.

The writer once learned a lesson out in the Ægean Sea that echoes back to 1921 now that the good ship "Professional Portraiture" is passing through a somewhat trying time. Our ship was drifting helplessly toward Cape Matapan. The mate sang out: "We're going to strike. Every man for himself!"

And it was so. To-day almost every photographer in every town is wanting the trade of every portrait-wanting person in that town who now goes to some other studio! But all the professionals of all the towns want the custom of the people who, close-fistedly, are learning to do without photographs until some "better times." The only way to get more business is to "go after it." The only way to go after business is to seek it personally or advertise, circularise, use the magical power of multiplied suggestion, order-canvassing, and business announcement that is provided by the printing machines of the local Press, and those of printers when used to multiply your message in the form of circulars.

The best way to consider advertising is to ask yourself what it is for. Advertising is used to sell goods. Therefore it must be salesmanship on paper.

What is salesmanship? It is suggesting to the other fellow that he wants, needs, or should obtain, something that you have for sale. Suggestion is the moulding of another's mind to think in the way that your mind is thinking. If you are thinking that more people should order photographs from you, you have got to work so that they shall think so too.

To do so you must light them up with some enthusiastic form of opening suggestion. You must then present your business propoaition. You must back this by strong arguments, for that, too, is a science of moulding thought. You must clinch these arguments by proof of the value of your service or suggestions, or by convincing reasons why the prospective customer should think the same way as you do.

You should then effect your climax, which is to get the order, or at least some promise of an order. That is the whole and the end of advertising. It is suggestion, plus salesmanship.—H. E.

Spotting Bromides.—On page 14 there is a reference to the spotting of bromides with diluted "Indian ink"—an excellent medium, though I prefer artists' waterproof ink when any colouring is to be done over the spotting. The waterproof ink requires dilution, and the way to dilute "waterproof" ink is to add water with which a drop or two of liquid ammonia has been mixed. Water slightly ammoniated is an excellent diluent for "waterproof" drawing inks—a fact not generally known.—R. P.

Coins as Weights.—The inclusion of the "Coins as Weights" table in the current "Almanac" (p. 505) is evidence of the continued use of coins for weighing, and it may be of interest to point out that the rumour to the effect that the new and "diluted" silver coinage is lighter than the old minting is untrue. The new coins are exactly the weight of the old, and may be used with safety. The new coins, however, are a little more easily damaged by chemicals than the old, and it is advisable not to let any photographic chemicals or solutions act upon them for any length of time, or one may have some difficulty in passing them—even on the tops of 'buses at night-time.—R.P.

Portsmouth Camera Club.—The club will hold its annual exhibition on the South Parade Pier, Southsea, from April 13 to 23. There are four open classes, in which silver and bronze medals and certificates will be placed at the disposal of the judge, Mr. F. J. Mortimer. The last day for the receipt of entry forms is March 31; the exhibits must be delivered on or before April 9. Prospectus from the Secretary, Mr. C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

FORTHCOMING EXHIBITIONS.

January 22 to February 5.—Northern Photographic Exhibition, Walker Art Gallery, Liverpool. Particulars from the Hon. Secretary, Liverpool Amateur Photographic Association, 9 Eberle Street, Liverpool.

January 27 to 29.—Birmingham Photographic Society. Particulars from the Hon. Secretary, Philip Docker, Birmingham Medical Institute, Edmund Street, Birmingham.

February 14 and 19.—Leicester and Leicestershire Photographic Society. Latest date for entries, February 5. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

February 19 to March 5.—Edinburgh Photographic Society. Latest date for entries February 10. Particulars from the Hon Secretary, G. Massie, 10, Hart Street, Edinburgh.

February 19 to March 12.—Scottish Salon, Dundee. Latest date for entries, January 31. Particulars from the Hon. Secretary, James Slater, Rosemount, Camphill Road, Broughty Ferry.

March 16 to 19.—Hackney Photographic Society. Latest date for entries, March 1. Particulars from the Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 13 to 23.—Portsmouth Camera Club. Latest date for entries March 31. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Latest date for entries, March 17. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications January 3 to 8:—

Colour Photography.—No. 383. Colour photography. Colour photography, Ltd., J. F. Shepherd and J. N. Thomson.

Printing Processes.—No. 1,090. Photographic printing processes. Graphische Kunstanstalten F. Bruckmann Akt.-Ges. and H. Kühn.

Shutter-Release.—No. 747. Automatic shutter-release for photographic cameras. V. Halla and W. Riehle.

Flash-Lamp.—No. 893. Flash-lamp for taking photographs. B. T. Hewson.

Washing Prints.—No. 100. Means for washing photographic prints or negatives. A. L. Price.

Shutters.—No. 1,068. Camera shutters and operating mechanism therefor. T. Wallace.

Aerial Mapping.—No. 1,110. Production of maps from overlapping oblique photographic views. Inag Internationale Aerogeodätische Ges.

Projection Apparatus.—Nos. 209 and 404. Automatically focusing projection apparatus. Kodak, Ltd.

X-Ray Photography.—No. 424. X-ray photography. N. E. Luboshey.

X-Ray Apparatus.—Nos. 489 and 679. Röntgen-ray apparatus. Reiniger, Gebbert and Schall Akt.-Ges.

Cinematographs.—No. 9. Cinematographs. H. Tallack.

Optical Projection. No. 783. Prismatic optical system for cinema projection. C. H. Frampton.

Colour Cinematography.—No. 396. Colour cinematography. C. H. Friese-Greene and R. O. P. Humphery.

Colour Cinematography.—No. 572. Method of producing coloured motion pictures. A. T. Saunders.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

STEREOSCOPIC CINEMATOGRAPHY. No. 152,367. (December 31, 1917). A cinematograph camera is fitted with two objectives set with their axes, say, 6.5 centimetres apart, and placed behind each at the proper distance is a reflecting prism. These prisms are directed towards one another, and between them is provided a second pair of oppositely directed prisms mounted one above the other in a slide placed in a plane at right angles to the plane through the axes of the objectives, the upper one, say, corresponding to the right hand objective and the lower one to the left hand objective. At a suitable distance behind these prisms a sensitive film is moved intermittently in the usual way, the period of registration of each consecutive film section with the exposure orifice corresponding approximately with the period during which each of the movable prisms is maintained in registration with its corresponding objective.

This may be effected in the following way:—A cam shaft is provided suitably geared to the usual mechanism. On this a cam having four projections is mounted. Below the cam is mounted on a pivot a centrally fulcrummed lever, one end of which engages the cam by a roller mounted on its end. A similar roller on the other end slidably engages a push piece mounted on the lower end of a guided rod whose upper end is rigidly attached to the slide carrying the pair of central prisms. A spring is preferably provided to maintain the parts of the moving system in contact and prevent vibration.

The lever may also have a control spring mounted on its axis.

The cam projections have each an arc of constant radius corresponding to the registration of the lower prism with its objective, and the recesses of the cam each have similarly an arc of constant radius corresponding to the registration of the upper prism with its objective.

The transition parts of the cam are so shaped as to give as smooth a motion as possible to the slide.

The film is carried, registered and driven as usual past an exposure orifice situated opposite the central prisms with its central transverse line in the plane of the objectives.

The camera is operated at a slightly greater speed than usual, say, twenty exposures per second.

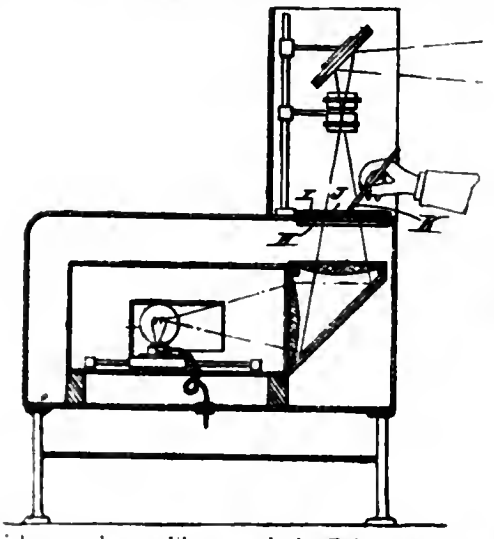
With this mechanism, films are produced which have two series of alternating pictures, one series taken through the one objective, the other series taken through the other of the stereoscopically disposed objectives.

Adjacent or consecutive pictures therefore belong each to a different series. More than two series may in some cases be employed.

When a film thus made is projected in an ordinary cinematograph projector, a stereoscopic result is obtained, as the two series of pictures on the one film thoroughly blend in the eyes of the observers.—Louis Lucien Ruffier, Villa Plaisance, St. Julien, Marseilles, France.

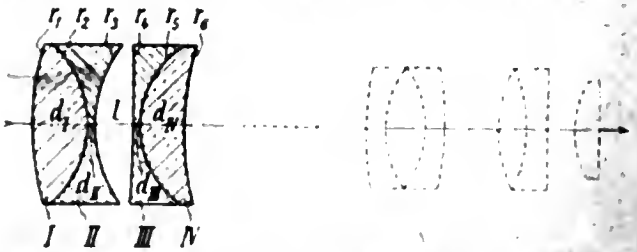
DRAWING BY PROJECTION.—No. 151,502 (November 22, 1919). The objection of the invention is to provide means whereby a person unskilled as an artist may produce a "slowly growing" picture in such fashion as to simulate the work of one highly skilled with the pencil or brush. Such object is accomplished by the placing in a suitable projecting apparatus between the source of light and the projecting lens, of a previously prepared drawing upon a transparent medium, and the super-position on this drawing of a plate covered with a coating which will transmit sufficient light to enable the operator to see the lines of the design or drawing, but yet be sufficiently opaque to prevent the projection of the design upon the screen. The operator then removes certain portions of the coating, for instance, the parts approximately above the lines of the drawing, and thus permits the light to be transmitted through the opaque coating and projected upon the screen, showing the drawing in the process of production. The removal of the coating at these parts is readily accomplished by means of a suitable stylus or other instrument.

In the diagram illustrating the optical arrangement, H, indicates a transparent plate on which has been drawn a picture or other delineation desired to be reproduced. I denotes a superimposed plate, also transparent, on which is coated a substantially opaque or translucent coating J, such as plaster of Paris or the



like, which may be readily scratched off by means of a steel stylus or other suitable tool K, adapted for the purpose, leaving the plate I clear and transparent for the passage of light wherever the "opaque" coating has been removed.—David John Williams and Tom Davies, 175 Palmer Avenue, Detroit, Michigan, United States.

LENSES FOR MINUTE IMAGES.—No. 145,023 (August 31, 1918). The invention relates to a constituent part of an optical device, which is designed for producing minutely reduced photographs, for instance of writings with a view to having these photographs of writings dispatched by carrier-pigeons. When, on employing such a device, an inconveniently great distance of the object to be taken is to be avoided, it will be found necessary to arrange for a small focal length of the device, but at the same time the aperture ratio must be large, so that the definition of the image does not get impaired by way of diffraction. These requirements are best complied with, in case the desired reduction is so great that a device of the type of a photographic objective is out of the question, by a device of the type of a compound microscope used in the reverse path of the rays, that is to say, in which that part which corresponds as to its construction to the objective of the microscope is turned towards the sensitised film, and that part which corresponds as to its construction to the ocular of the microscope faces the object to be taken. If, however, a microscope of the ordinary type is employed, that is to say, one in which the ocular has a collective effect as well,



larger objects cannot be imaged satisfactorily because the astigmatism of oblique pencils and the chromatic difference of the magnification being sufficiently removed, it will generally be found impossible also to correct the curvature of the image-field in a sufficient measure. The reason for this is, that, on employing a collective ocular of a microscope, it is not very well possible to let the image formed by this ocular have a curvature of that particular sense and amount that the objective of the microscope would just form a plane image of the said image.

According to the invention the last named problem may, however, be solved, if that group of lenses (corresponding to the ocular of a microscope) which is to be located in front of the collective group of lenses corresponding to the objective of a microscope (and generally consisting of a suitable microscope-objective) be so arranged as to be dispersive (which in oculars for microscopes has hitherto already been practised in certain cases), whereby, however, this group should consist of two dispersive members separated from one another, each of these being composed of at least two lenses.

As a matter of course the new group of lenses may also be used in a device acting in the reverse path of the rays, therefore, for producing greatly enlarged photographs, or for projecting under high magnification.

The drawing shows a section through a group of lenses corresponding to the invention in which each of the two members consists of two lenses cemented together.

In the following tables the radii of curvature, the lens-thicknesses, the distance apart of the two members, and the kinds of glass are enumerated.

Measurements in millimeteres.

$r_1 = +\ 24.106$	$d_{\mathrm{I}} = 4.5$
$r_2 = -\ 8.51$	$d_{\mathrm{II}} = 0.5$
$r_3 = +\ 11.29$	$l = 3.0$
$r_4 = -212.831$	$d_{\mathrm{III}} = 0.5$
$r_5 = +\ 7.913$	$d_{\mathrm{IV}} = 3.5$
$r_6 = +\ 24.917$	

Kinds of Glass.

	n_D	v
I and IV :	1.57240	41.7
II and III :	1.57088	57.5

The focal length of the whole group of lenses amounts to 20.16 mm. If, as indicated in the drawing, behind the group of lenses an apochromatic microscopic-objective having a focal length of 16 mm. be located, of which the focal point facing this group of lenses has a distance from the focal point of this group of lenses which faces the said focal point amounting to about 165 mm., the whole arrangement will allow, for instance, to form an image in a plane of a plane object, which is situated 750 mm. away in front of the dispersive group of lenses, reduced six hundred times without, on an angle of the field of view facing the object amounting to almost 30 deg. being involved, a disturbing lack of definition becoming evident.—Carl Zeiss, Jena, Germany.

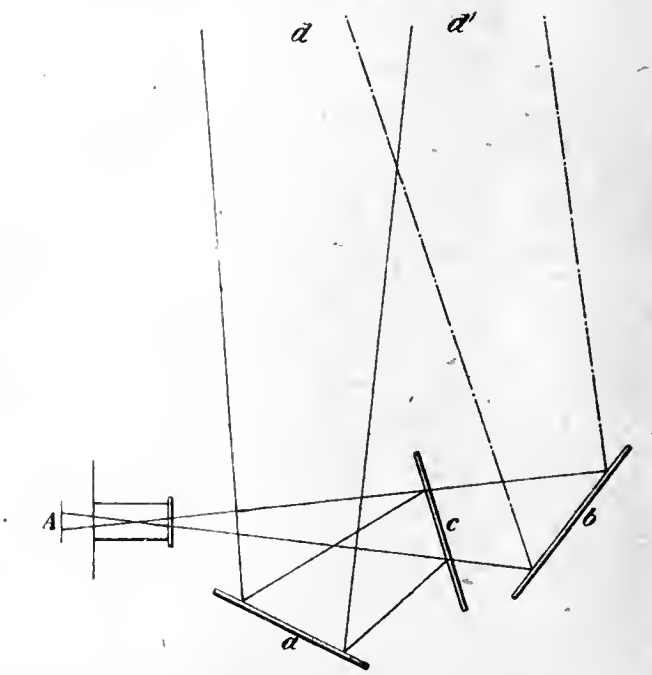
Lantern Screens. No. 154,459. (December 12, 1919).—Butter cloth, composed of an opaque or semi opaque material, is loosely woven in such a manner that the fabric shall form a multiplicity of apertures of uniform shape and dimensions. Preferably the major proportion of the filaments composing such fabric run diagonally across the screen from one or both sides thereof. Screens are produced in the following manner:—The reinforcing fabric is prepared by coating the same with melted wax, celluloid or other translucent substance after it is stretched upon a frame. Should the coating thus applied prove rough or lumpy, in order to render such surface uniform, the screen is suspended in a chamber and the temperature raised until the wax becomes sufficiently fluid to run into and completely fill the interstices in the fabric, each of which forms a small panel of translucent wax or the like.

The coating process up to this stage is one hitherto employed with fabrics having rectangular apertures. In carrying out the invention, however, as soon as the interstices or apertures in the fabric are evenly filled and while they still retain a sufficient degree of fluidity, the screen is supported in a horizontal position so that each panel of wax or the like sags and becomes convex on its under surface, thus imparting to the screen a surface composed of a multiplicity of nodules or projections which are convex, pyramidal, conoidal, or paraboloidal in form according to the weaving of the fabric.

In this condition the heat having been withdrawn and the chamber cooled the wax is allowed to set, and the screen coated, if desired, with a suitable transparent varnish.—William James Marks, 1b, Ripon Street, Greenheys, Manchester.

Duplex Cinematograph Projection.—No. 149,649 (August 11, 1919.) The invention relates to a method of producing two cinematographic representations simultaneously on different parts of a projection screen by means of a single cinematograph.

In the drawing A indicates a cinematograph apparatus at the side of the theatre, whilst *a* and *b* denote two mirrors arranged at an angle in relation to the optical axis of the objective, as shown. A transparent mirror disc c is so arranged between the mirrors *a* and *b* that two projections result, the image being reflected once by means of the transparent glass pane c on to the mirror



a and also passing through the glass disc on to the mirror *b*. The image is projected from *a* on to the lower half *d* of the screen, which half is made opaque, whilst the image is projected from *b* on to the upper transparent half *d* of the same screen. The arrangement is such that a laterally correct representation of the picture or image is obtained on the screen viewed from either side thereof. If so desired two separate screens or projection surfaces may be used instead of a single screen.—Messter-Film G.M.B.H., 27/28, Oberlandstrasse, Berlin-Tempelhof, Germany.

New Apparatus.

Pentac Anastigmat Cinematograph Lenses, Series XIX. f/2.9. Made by J. H. Dallmeyer, Ltd., 11, Regent Street, London, S.W.1.

This new series of lenses for cinematograph cameras, recently designed by Mr. L. B. Booth, represents a further development in the production of a lens of ultra speed, and at the same time of critical quality of definition, both elements of great importance to the user of a cinematograph camera. The lenses are issued of the aperture of *f*/2.9, that is to say half as rapid again as one of *f*/3.5, and in some of the focal lengths it has been found possible to exceed even this speed, and to provide an aperture of *f*/2.8. The lenses yield extremely fine definition and we have no doubt will be widely appreciated by cinematographers. Equally they form most valuable objectives for direct photo-micrography without a microscope on the lines which were recently the subject of a paper and demonstration by Mr. Martin Duncan at the Royal Photographic Society. Messrs. Dallmeyer issue four focal lengths of 1½, 2, 2½, and 3 inches. The price of the first two is £8 15s.; of the 2½ inches, £9 15s., and of the 3 inch, £10 10s. The objectives are also supplied in focussing mounts at somewhat higher prices.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, JANUARY 24.

Bradford Photographic Society. "Nature Poets and Nature Pictures." P. Lund.
Cleveland Camera Club. Paget Colour Slides.
Cripplegate Photographic Society. Members' Print Competition.
Dewsbury Photographic Society. "Development by Time and Tank." A. Dordan-Pyke.
Dundee and East of Scotland Phot. Soc. "Mounting the Print." W. B. U. Patterson.
South London Photographic Soc. "Photographing Wild Flowers"
Stalybridge Phot. Soc. Annual General Meeting.
Walthamstow and District Phot. Soc. "A Further Chat on Pictorial Composition." S. Bridgen.
Willesden Photographic Society. "Some Notes on the English School of Painters." J. Vacy Lyle.

TUESDAY, JANUARY 25.

Royal Photographic Society. "Serbia and Jugo-Slavia before the War and After." Dr. F. May Dickinson Berry.
Bournemouth C.C. Bromide Enlarging and Combination Printing.
Dennistoun Amateur Photographic Association. Whist Drive.
Doncaster C.C. "After-Treatment of Negatives." A. Dordan-Pyke.
Exeter Camera Club. "With Allenby through Palestine." Messrs. Butcher, Ltd.
Hackney Phot. Soc. Developing Demonstration. G. H. Capper, H. W. Fitch, and W. Selfe.
Leeds Photographic Society. Autochrome Evening.
Leith Amateur Photographic Association. "Preparing Prints for Exhibition." Mr. Robb.
Manchester Amateur Phot. Soc. Annual Meeting.
Portsmouth Camera Club. "Some Country Rambles with a Reflex Camera." Dr. B. Stone.
Sheffield Photographic Society. "Bromoil." F. A. Tinker
Welfare Camera Club, Linthouse. Bromide and Gaslight Printing

WEDNESDAY, JANUARY 26.

Accrington Camera Club. "Enlarging." Langstaffe.
Croydon Camera Club. Annual General Meeting.
Dennistoun Amateur Photographic Association. "An Elementary Talk on Lenses." G. E. Burrell.
Ilford Photographic Society "Some Continental Recollections." F. C Newmarch
Leicester Phot. Soc. "As I was Going to St. Ives." E. S. Maples
Partick Camera Club. "A Tour in Germany." K. M. Alexander
Photo-micrographic Society. Members' Evening.
Rochdale Phot. Soc. Members' Ideas of Good Negatives

THURSDAY, JANUARY 27.

Brighouse Photographic Society. "Old Brighouse." G. Hepworth.
Camera Club, The. "Psychology in the Studio." C. P. Crowther.
Everton and District Photographic Society. "Cathedrals I have Visited." The President.
Hammeramith (Hampshire House) Photographic Society "Retouching on the Negative." A. J. Lyddon.
Hull Phot. Soc. Lecturette: "Haddon Hall." J. T. Dyson
North Middlesex Phot. Soc. Annual General Meeting.

FRIDAY, JANUARY 28.

Bedford Camera Club. R. W. L. Phillips.
Dennistoun Amateur Phot. Association. Trimming and Mounting

SATURDAY, JANUARY 29.

Woodford Phot. Soc. Annual Dinner of the Affiliation.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, January 18, the president, Dr. C. H. Bothman, in the chair.

Capt. C. W. R. Knight, M.C., F.R.P.S., delivered a lecture on "Falconry," illustrated by a number of lantern slides, many from negatives taken under difficult conditions, yet serving to illustrate this branch of nature study to which Capt. Knight has devoted himself, and more particularly in relation to the cinematograph.

On the proposition of the Chairman a very hearty vote of thanks was accorded the lecturer.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held at 116, Hanover Street, Edinburgh, on Monday, January 10, 1921, at 8 p.m. Present: Miss Bertram, Messrs. F. D. Young, George Balmain, J. B. Johnston, Norman Thomson, Laird, Aikman, Campbell Harper, and Moffat. Apologies for absence were received from Miss Grey, Miss Grace D'Arcy, and Messrs. Drummond Shiels, Fergusson and Coltart.

The secretary read the report of the third annual dinner, held on December 6 last, which was approved. The secretary submitted the accounts in connection therewith.

The secretary read a letter from Miss Grey offering to contribute £1 towards the cost of providing a half-watt installation for the lighting and posing composition class at the College of Art, and Mr. Moffat intimated that he would also contribute £1 for that object. The meeting thanked these members, and also Mr. E. D. Young, for their donations.

The secretary read a letter received from the secretary of P.P.A., London with reference to the Society's communication anent the question of "free sittings." The secretary of the P.P.A. stated that the matter had been seriously, lengthily, and sympathetically discussed by his Council, and the following resolution had been passed:—

> "That this Council, having considered the letter from the Edinburgh Professional Photographers' Association, have come to the conclusion that, while deprecating the giving of free sittings as a business system, they do not feel that they are in a position at the present moment to take effective action in the matter."

The secretary also read an excerpt from the editorial notes and the minutes of the Council in the "P.P.A. Circular" condemning this reprehensible practice.

The meeting, while regretting that the P.P.A. could not co-operate with them in making some official pronouncement, felt that the airing of the grievance might have some beneficial effect. One of the members stated that a few days ago a customer who was being married shortly had received a letter offering "free sittings," and in which it was stated that the copyright would belong to the sitter, and that they would not publish the photograph without her consent. This apparently was the result of the Society's advertisement re "free sittings" in June of last year, and was considered an interesting feature.

The question of the reproduction charges, which was adjourned from last meeting, was further considered, but it was resolved, after some discussion, to let the matter lie over in the meantime.

The members thereafter considered what arrangements should be made for the holiday season 1921. The meeting recommended closing for the second fortnight of August, and Mr. Moffat, Messrs. W. and F. Drummond Young, and Miss Bertram indicated they would close during that period. It was proposed to delay for a month, so that any other members may desire to join in the scheme. It was agreed to insert a joint advertisement in "The Scotsman" some time in July and August notifying to the public the businesses which would be closed.

Mr. F. D. Young reported that the half-watt installation had been obtained and placed in the lighting and posing composition class at the College of Art, and was a great improvement.

CROYDON CAMERA CLUB.

Mr. B. T. Rose gave a highly interesting demonstration, entitled "What Can be Done in a Photographer's Workroom." Assuming a note of interrogation, the answer is "A lot of things." The many useful tips and contrivances brought forward, the majority impossible or difficult to describe without drawings, clearly illustrated that the lecturer must have occupied a front seat when the gods distributed gifts of ingenuity, and grabbed far more than his share.

Several of the tips were, however, admittedly not original. Selecting one of these to start with, quite a nice finish can be given to a photograph mounted on card without margin. A strip of No. 1 glasspaper is glued on to a slip of wood and run along the edges. A strut on the back enables the photograph to be placed upright, and to furnish yet another knick-knack for the collection of dust.

Carriers of strawboard answer well and cost practically nothing. The difficulty is to get these to fit turn-buttons in cases where they are required. Drive a pin through the back in correct position; slightly bend over to judge length required; snip off superfluous bit, insert a sheet of glass in carrier, and further bend the end of

the reduced pin until it comes in contact. These simple turn-buttons answer excellently.

In the construction of strawboard or cardboard boxes, etc., it is usual to half-cut through to allow the card to be bent round at right-angles. This has obvious disadvantages, and the lecturer showed a far better way. A piece of wood, longer than the card, has a groove made along its length with a tenon-saw, and opened slightly V-shaped with glasspaper. A groove about 1-16 in. deep and a trifle wider is sufficient. A strip of hard wood is taken and the end fashioned to a point with curvature running up to it similar in contour, though more acute, to a spoon bow (convexity outwards) of a boat. A pencil line is drawn along the card where the bend is required, and the extremities laid in line with the groove; heavy pressure is then applied along the line, with a gliding motion, by the pointed piece, and the trick is done. He showed many useful cases and a nest-of-drawers made out of card, one case fitting a limp canvas camera case and converting it into a stiff one, a division being thoughtfully allowed for a flask.

A capital strop, or hone, for sharpening knives (great, it was said, for carving-knives) consists of a strip of wood on which linoleum is glued. It is oiled, and fine carborundum, No. 1 or No. 2, applied. An attempted appropriation by the secretary of a sample strop, kindly presented by Mr. Rose to the "office boy," at this juncture brought the proceedings to a fine edge.

Quite neat was a method of grinding a ground-glass patch on a bottle. Procure carborundum powder as aforesaid and a strip of glass about 5 ins. long by ¾ in. broad. Tie a piece of thin card round the bottle, its upper part finishing where the lower edge of the patch is to stop. Using this as a guide, and water as a lubricant for the powder, and keeping a finger over the point where pressure is applied, a patch is quickly ground, which can be written on with pencil, or better, red chalk. Round and flat bottles can be treated: with the latter any depressions may require persuasion with the tip of the glass. Water acting perfectly as a lubricant, various alternatives, such as camphor in turpentine, were, of course, suggested.

It should be mentioned that the proceedings were uplifted at the start by Mr. Rose reading in clerical style a discursive but extremely elevating article. At the close was some lofty moralising on the nobility of work. He cannot help these vagaries, for they are inbred, and even extends his generous, loving sympathy to the jobbing workman, who usually deserves hard labour, and unfortunately fails to secure it. The moral contagion spreading, Mr. Harpur sorrowfully declaimed against society for preferring the man who works with his brains to the one who works with his hands. In his opinion, the man who counts is he "who works with his brains in front of his hands," pickpockets, presumably, excepted. After a brisk encounter between Mr. Sellors and Mr. Jobling on the respective merits of crocus and rouge, in which such weighty arguments as "What rot!" and "Nonsense" were freely applied, a most hearty vote of thanks was accorded Mr. Rose for an evening full of practical suggestions.

News and Notes.

Portraits by Mr. Marcus Adams and Mr. Bertram Park form a small collection, which is being shown by the Hammersmith Photographic Society at Hampshire House, Hog Lane, W.6, during the next few weeks.

Messrs. Bassano are vacating their studios and premises at 25, Old Bond Street, which they have occupied for no less a period than 45 years. In consequence of termination of the lease, they have had to seek a new home, and are establishing themselves at 38, Dover Street, at the end of the present month.

Bargains in Apparatus.—Messrs. Wallace Heaton, Ltd., 17 to 27, Change Alley, Sheffield, send us their January list of second-hand cameras, enlargers, lenses and other apparatus, a compilation running to 52 pages, and including a very great variety of goods at all prices. The list is obtainable free on application.

Commercial & Legal Intelligence.

Legal Notices.—Notice of intended dividend is given in the case of Bertie Owen Emms, picture frame maker, 18, Norwich Road, and trading at 11, Arcade, Lowestoft. Proofs must be lodged on or before January 25 with A. Granville White, 14, Old Jewry Chambers, E.C.2.

NEW COMPANIES.

C. and A. G. Lewis, Ltd.—This private company was registered on January 10 with a capital of £3,000 in £1 shares (2,500 ordinary and 500 10 per cent. preference). Objects: To take over the photographic, printing and other business carried on by C. Lewis as C. and A. G. Lewis at 97 and 99, Sherwood Street, Nottingham. The first directors are: C. Lewis (permanent managing director and chairman), Dunelm, Mapperley Plains Road, Nottingham; Mrs. A. G. Lewis, Dunelm, Mapperley Plains Road, Nottingham; C. R. Harrison, 24, Gill Street, Nottingham; J. S. Harrison, 24, Gill Street, Nottingham. Secretary: C. R. Harrison. Registered office: 97 and 99, Sherwood Street, Nottingham.

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

WARMING THE STUDIO.

To the Editors.

Gentlemen,—In a recent number of the "B.J." a correspondent spoke with approval of a new invention for heating rooms, and strongly recommended it for studios. I have never heard of it myself, and while it may be very good for ordinary rooms, I do not think it could possibly succeed for warming a studio of the usual size, as I understand it is heated by either gas or electricity. The latter would be horribly expensive and quite inadequate for the purpose. Gas, at the present time, is bad and dear. In our enlightened district we pay 4s. 10d. per 1,000 feet, and to warm a large studio would be very costly, and it would be advisable to have a flue to carry away the fumes. I know there are gas radiators which are said to condense all the products of combustion, but I know also that none of them do it. Some of them do condense some of the fumes, as well as a good deal of water, but enough fumes escape to play havoc with curtains, curtain rods, lens mounts, and all metal work in the place. I have had a good curtain reduced to tinder in a couple of years, and brass work corroded a beautiful green in less time.

The studio must be warm; one cannot get good portraits of sitters when they are shivering with cold. I have seen ladies come into the studio in winter in evening dress looking ten years older than they should through cold. In a few minutes in a warm room they begin to look younger, and their faces plump up like a shrivelled apple in an air pump. Then one must be prepared at almost any time to photograph a baby without any clothes, a silly idea, but fond mothers will have it that way. Only a week or two ago when the supply of anthracite was short and we had to depend on a gas radiator, I had great difficulty in persuading a young mother not to strip a poor baby naked in the cold studio.

I suppose the ideal method of heating would be a system of hot-water pipes all over the establishment, dark rooms included, supplemented in offices and artists' room by an open fire for ventilation. In some large blocks of offices the landlord has installed a heating apparatus for the whole building, and the photographer who has his studio in such a building is fortunate. But even when the studio is heated by such means it is advisable to have some form of stove or fireplace to increase the warmth when necessary.

I have tried several patterns of stoves; the old-fashioned "Tor-

"Ideal" slow combustion is good, but liable to be dusty and dirty, especially as the fire has to be lighted every morning. The best of all, in my experience is the kind specially designed for burning anthracite; the fuel is clean to handle and quite smokeless, and gives out intense heat. The rate of combustion can be regulated to the greatest nicety, and the stove, if attended to once a day, can be kept alight from October to April. But in studios it may be necessary to re-light it on Monday morning.

These stoves are not easy to light, and I have found it saves a great deal of trouble if a handful of ordinary soft coal is used to start it burning. With such a stove properly handled there should be no dust, except when the stove is cleaned out for re-lighting, and very little even then. All the rest of the week the ashes are shaken into a shut-up drawer, which can be carried out of the room. I find one such stove will keep a large studio comfortably warm, except in the very coldest weather, when a gas radiator is used if necessary. Unfortunately anthracite is not easy to get nowadays, especially if storage room is small. I have sometimes had to wait a month for a supply owing to shortage of trucks. Nuttine, or small coke, may be used in an emergency, but it gives only a fourth of the heat of anthracite, and burns away so quickly that it is useless to try to keep the fire on all night. With anthracite the stove is filled at night and the draught regulated to keep the fire just alight till morning, when the draught is increased and the ashes well shaken out, and in a short time the stove is throwing out an intense heat. The all-night fire is useful in winter, as it keeps the studio slightly warm and melts any snow as it falls. Unless the studio has a fireplace it is necessary, of course, to have a stove pipe, not a beautiful object, I admit, but I do not find it very unsightly; in fact, I do not think any one notices it, as it is in a shadowy part of the room. The ordinary galvanised iron pipe should not be used, as the fumes, presumably sulphurous, soon corrode it away; a strong cast iron pipe, such as used for sprouts is best and looks, perhaps, less unsightly than galvanised iron.

After several winters' experience I am quite satisfied that anthracite is the best and cheapest for the ordinary studio. I would not go back to gas or coal and coke stoves. The pattern of stove can be used for workrooms, and even dark-rooms, but in the latter would be too hot unless they were large, and it would be necessary to screen it from splashes of water and chemicals. But when I become wealthy (*when!*) and build my ideal establishment, the whole place will be heated with hot-water pipes, with open fireplaces wherever possible, for, after all, nothing looks so comfortable and cosy as an open fire. One hears a good deal of central heating for houses in these days, with radiators instead of fireplaces, but I cannot imagine a family sitting round a radiator on Christmas night.

It may be as well to add that the anthracite should be selected for the kind of stove used; for the ordinary size of stove the fuel should not be larger than "walnuts."—Yours faithfully,

CONTROY.

FACTORIAL DEVELOPMENT.

To the Editors.

Gentlemen,—The difference of opinion between Mr. Alfred Watkins and myself as to the value of the factorial method of development for negatives exposed upon outdoor subjects, or under other variable light conditions, can be narrowed down to a very simple issue. We are agreed that a variation in exposure gives rise to a variation in the time of appearance of the image and a corresponding variation in the calculated total time of development. We disagree, however, as to the amount of this variation in exposure which is probable in ordinary outdoor negative work. Mr. Watkins considers that accuracy in exposure to within an error of 50 per cent. can be accomplished with the aid of an exposure meter. If that be so, then I admit at once that the accuracy of factorial development in outdoor negative work is comparable with its accuracy in the development of bromide prints and lantern plates, the correct exposures for which have been ascertained beforehand by trial. I am of the opinion, however, that the errors in exposure in the outdoor negative work are frequently at least as 1 to 4, and are fairly illustrated by my two experimental plates, one of which was given 1/10th second and the other 1/45th second exposure, and which upon development yielded very different times of first appearance of the image. It is well known that the plate speed number upon the plate box does not necessarily indicate the true speed of the plates enclosed within. Plates may vary in speed from box to box (batch to batch) by 50 per cent. Two plates within the same box have been known to give different true-speed readings. It is also notorious that photographic shutters are not only wrongly marked, but also frequently fail to repeat exposures at any one setting to an extent which makes it futile to get them tested and re-marked. I have known a shutter give 1/20th second upon one occasion, and upon a subsequent occasion at the same setting it gave 1/30th second. The records of the National Physical Laboratory are rich in similar examples. Without taking any account of other pitfalls in exposure, it is obvious that if we attempt to give a meter-calculated exposure of 1/10th second with a plate whose marked speed is 200 H and D, and set the shutter accordingly, and if the real speed of the plate is 150 H and D, and the shutter, working quickly, gives 1/15th second, then we have upon that plate an effective exposure which is *unwittingly* only half what was intended. In a like manner errors in the opposite direction give rise to an exposure of double the one intended. This is precisely the range of error provided in my experiment to which Mr. Watkins takes exception. If it be admitted that this degree of error is common—and I submit that it is not only common, but frequently exceeded—then Mr. Watkins is wrong and I am right and the factorial method is less suited to the development of outdoor negatives, because of the possible exposure error, than it is for the development of accurately exposed materials.

I agree with Mr. Watkins that, if the correct exposure for a piece of bromide paper were 1 second, and either 2 or 4 seconds were given instead (an error in exposure comparable with my plate experiment), then the factorial method applied to bromide paper would be found to be equally inaccurate. I am glad that Mr. Watkins does go so far as to admit that such a degree of error in exposure seriously handicaps factorial development. But it is precisely because we can eliminate the possibility of such errors of exposure in bromide paper by making trial exposures first that bromide prints and outdoor negatives are not comparable. The ordinary photographer can be sure of the exposure for bromide paper and lantern slides by means of an experimental trial; he cannot be sure of his exposures in outdoor negative work, because he has no means of making a trial, hence the applicability of factorial development to the former, and its inaccuracy in the case of the latter class of work.

I am glad that some of the sources of error associated with development by time alone were pointed out. They are insufficiently known and appreciated. The list could be extended with advantage. The calculated time of development must also make proper allowance for the relationship between the total range of light-intensities in the subject and the exposure scale of the printing process contemplated. Mr. Watkins himself ignored this variable when he departed from factorial development in 1910 and adopted "thermo-time" development in tanks, in order to develop more than one plate at a time and avoid a red dark-room lamp. It does not in the least surprise me, therefore, that he was more satisfied with the "factorial" results compared with his "thermo-time" results. The inaccuracy of the time method so practised was greater than the inaccuracy of the factorial method. Unless *all* the factors which govern the time of development are taken into consideration, it is reasonably certain that the result will be imperfect. The factorial development of outdoor negatives is a method more trustworthy than development by inspection. Time development properly conducted is more trustworthy than either. Time development is *not* properly conducted when a group of exposures are developed in a dish or a tank for the *same* time. I did not use the word "standardised" in respect of exposures given to bromide papers, so that the remarks made in criticism thereof do not apply. On the other hand, I did recommend trial and error in the manner which Mr. Watkins describes as the only way of getting a correctly exposed print.

The subject is of considerable interest, and the issue is a simple one. Can ordinary photographers estimate outdoor exposures to within an accuracy of 50 per cent. with reasonable frequency with

out the aid of a check upon the actual speed of the plate in use which Mr. Watkins himself is able to accomplish, or is a range of inaccuracy of 400 per cent. quite common?—Yours faithfully,

B. T. J. GLOVER.

Sunnymere, Birkenhead Road, Meols, Cheshire.
January 16.

To the Editors.

Gentlemen,—I have read Dr. Glover's articles on factorial development with much interest, and consider that they are a valuable addition to the literature on the subject of systematic development, but I am afraid that I cannot agree with some of his conclusions, and, now that Mr. Watkins has taken up the cudgels in defence of factorial development for negatives, I beg leave to give some of my own experiences on the same subject.

I have made very considerable use of both therme time and factorial development for the past 25 years, and my conclusions are that both methods have their good points, but for critical work I should always use the factorial system. Like Mr. Watkins I have been let down by tank development when the chemicals or the emulsion have not been what I expected, but I do not recall a single instance of being let down by the factorial system.

My usual practice, when developing a number of exposures, is to make a test with two or more plates in one dish, taking note of the average time of appearance and the total time of development. These plates are fixed and examined, and, if found satisfactory, the rest of the batch developed for the same total time, but the time is first indicated by the factorial system. The only variation I make is to develop interior subjects for two-thirds of the time given to exteriors. Needless to say that the exposures are carefully calculated by an actinometer or other means, and except in the case of a sheer fluke, I find my negatives very even.

I can well believe that where the exposures are haphazard the factorial system would fail, and that thermo-time would be far preferable, and, strange to say, I have not found the factorial system satisfactory for process negatives all exposed by artificial light. There are good reasons for this, which would take up too much space to explain here.

There is one peculiarity of factorial development which I have not seen mentioned, and that is in connection with the dilution of the developer. I recently made some experiments with the object of testing the advantages of surface development as opposed to depth development; my tests were made solely with the object of noting the effect upon halation. I failed to get halation under any conditions, but I found that the negatives produced with dilute developer were of a totally different character from those produced with a normal developer.

My subject was an interior facing a long row of windows, but the day was dull and damp, and there was a fair amount of haze in the room. Three exposures were made, and identical exposures were given; Imperial pyro-metol was the developer, and the first negative was developed with half-normal strength; time of appearance, 20 secs.; factor, 6; total time, 2 minutes. The developer was diluted to one-eighth normal strength for the second negative, the time of appearance being 90 secs.; total time, 9 minutes. The negatives when fixed differed very considerably in contract. No. 1 was a fair average negative for the existing conditions, but No. 2 was very much thinner in the high-lights, and the shadows contained a much higher proportion of fog, and not a particle more detail than No. 1. No. 3 was then developed with full strength developer, the time of appearance being 20 secs., the same as No. 1, but at the end of 1½ minutes, the high-lights being well through at the back, and it being quite obvious that to continue would be to over-develop, it was taken out and fixed; the result being that it is the best negative of the three. The high-lights are denser than No. 1, and the shadows are clearer than either No. 1 or No. 2, and the shadow detail is brighter and stronger; so everything points to strong developer with a low factor being better than a dilute developer with a high factor as far as quality is concerned. But another point which stands out is that the same factor will not do for different degrees of dilution.

As regards bromide printing, I agree that the factorial system is the best, but I cannot agree that so high a factor is necessary, or it may be that different developers or different formulæ require widely different factors. Anyway with amidol used with anything from 1½ to 6 grs. per oz., I find a factor of 6 to be ample for either black and white or sepia prints.

To sum up, my conclusions are that both systems of development are very good servants, but not equally good masters, and that a judicious blend of the two, as suggested above, will be found useful for plates or papers.—Yours faithfully,

E. A. BIERMAN, F.R.P.S.

Birmingham, January 15.

To the Editors.

Gentlemen,—Dr. Glover has earned our thanks for bringing Mr. Watkins out of his shell and causing him to pen the interesting article appearing on p. 15 of your last issue. I have for more than twenty years been a great believer in and a user of the factorial system of development, and I never fail to recommend it to those who meet with difficulties in development.

I could never understand why such an ideal system of developing correctly-exposed negatives has been allowed to fall into the background, one hearing very little of it to-day, and meeting very few who know anything about it.

It has been a great mistake not to keep the table of factor numbers up-to-date. All the tables I know of—even the latest, i.e., that in the current "Almanac"—are rather antiquated and incomplete. Mr. Watkins is, I know, a busy man, but if he could see his way—makers of plates, films and developers perhaps helping him—to send you for publication a corrected, up-to-date and complete list, it would be of great assistance to all of us. Other workers with more spare time than Mr. Watkins might perhaps do it, but "Watkins numbers" from Mr. Watkins himself would carry greater weight and be more acceptable to most of us.

Plate and developer makers have been very behindhand in ascertaining and giving us the factor numbers of their formulæ and products, and requests for them have often brought confessions of ignorance of the figures or suggestions for "approximate" numbers.—Yours faithfully,

GODFREY WILSON.

January 15.

THE POSITION OF PHOTOGRAPHIC SOCIETIES.

To the Editors.

Gentlemen,—The letter from the hon. secretary of the Catford Camera Club, published on page 27 of last week's "B.J.," comes as a sort of tonic after the depressing effect of "Fuller Hope's" lachrymose screed, though I must confess that I look a little askance upon the communication from Mr. Coleman. The latter, I think, is much too sanguine, whereas the originator of the correspondence is far too pessimistic.

The Catford secretary, to my mind, pictures the position of only one society, and this, of course, his own. I am given to understand that the founder, president, and moving spirit of the Catford Club is a well-known teacher of photography at the L.C.C.'s local evening classes, and that the club was at first made up mainly of the president's photographic pupils. Other beginners, I am told, have been admitted to the membership, but the fact of its origin remains. If this be true, how can we compare the club with others? Before we can fathom the reasons of this new club's extraordinary success we should know the number of the president's past and present pupils in the club, and the parts they play in it.

No other society has, I believe, been founded and run under such favourable conditions, and, having a fairly large percentage of real beginners—and, obviously, enthusiastic workers—as a strong foundation, the club ought of necessity to be a huge success—for a time at any rate. But what will happen when most, if not all, of these beginners become expert workmen, as they must do very soon under the rulership and instruction of such a capable experimentalist and teacher as their president? I venture to predict that the members will make rapid progress in the art of photography, and that they will very soon be tired of instruction evenings, and yearn either for what Mr. Coleman calls "a long series of lantern and other evenings of the usual sort," or drop photographic club life, and perhaps photography altogether.

I have a great admiration for Mr. Coleman's enthusiasm (I wish there were more like him), but it would be very interesting to have

another report from him, say a year or two hence, when his unique collection of beginners will have become "old hands" and really good workers. Catford, if my information is correct, has not an unlimited supply of persons who require photographic instruction.

It should also be remembered that the Catford Club is not an oasis in a desert, and that for many years photographers in the district have been well catered for by two other societies within a short walk of the new club's headquarters.—Yours faithfully,

L. T. W.

TWO OR THREE DIMENSIONS: IDEALS IN PORTRAITURE.

To the Editors.

Gentlemen,—Mr. Edward Drummond Young seems to be annoyed. I'm sorry. I maintain that it is pernicious to encourage photographers to adopt the two-dimensional, or any other "stunt" of modern painting as opposed to the spirit and letter of photography, scientific and artistic.

I could readily reply to all the points in Mr. Edward Drummond Young's letter, but cannot see that any useful purpose would be served by doing so.—Yours faithfully, F. C. Tilney.

Walden, Cheam, Surrey.

January 17.

RAILWAY PHOTOGRAPHERS.

To the Editors.

Gentlemen,—I was interested in reading Mr. T. A. Scotton's letter in your issue of the 7th inst. In that communication he asks for information as to the first railway photographer, and, in reply, I would like to record the following facts. Shortly before his death, Mr. F. A. Bridge and I compared notes, and I learnt from him that he had photographed in the Bow works of the North London Railway. It so happened that—due to my father's influence—as a youngster, I was allowed the privilege of entry into these works in 1869-70, and remembered having seen a photographer at work there. That man, I afterwards learned, was the late Mr. Bridge, as related by himself.

I do not know whether he was the official photographer to the railway in the same sense that Mr. Scotton and his father were attached to the Midland Railway, or merely called in as occasion required.

Trusting that this is of sufficient interest to appear in the "B.J."—I am, gentlemen, yours faithfully, G. W. Atkins.

Elstree, Herts.

January 17.

THE PETZVAL ORTHOSCOPIC LENS AND THE TELEPHOTO

To the Editors.

Gentlemen,—It is agreeable to note in the lecture by Professor Conrady the appreciation awarded to the genius of Petzval. I do not think that photographers have duly recognised what they owe to the work of this distinguished mathematician, whose portrait lens, Professor Conrady remarks, is made practically in its original form at the present day. It was this lens, combining as it does large aperture, and consequent rapidity with exquisite definition, that enabled photographers to build up such a large and successful business in portraiture before the arrival of emulsion rapidity.

Petzval's second lens, known as the orthographic or orthoscopic, also merits attention as the forerunner of the telephoto lenses. Some three or four years after its introduction, a proposition was introduced at the Photographic Society of Great Britain—I think by Mr. Malone—to have a mark engraved on the lens tube, indicating the place from which the focal distance could be measured, and I then pointed out that with the orthographic lens it could not be done, as the nodal point was outside the lens. This, of course, indicates a longer focus, and consequent larger image than would be inferred from distance between the lens and the image. The magnification was not great, but it existed, and the principle, that of placing a negative lens behind the positive, is that adopted in telephoto lenses.

To Mr. T. R. Dallmeyer belongs the credit of recognising how an extension of the principle illustrated in the orthographic lens might be utilised in the production of a telephoto lens, with a useful degree of magnification resulting in the production of the well-known telephoto lens.—Yours faithfully, W. E. Debenham.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

R. H. I.—Apart from the Röntgen Society, the only association we know is the Society of Radiographers, the secretary of which is Mr. George F. Westlake, Electrical Department, Cancer Hospital, Fulham Road, London, S.W.6.

H. T.—It has been definitely stated by the Home Office, on application of the Professional Photographers' Association, that the taking of portraits by appointment at a studio on the half-day weekly holiday is not contrary to the Shops Act.

M. F. S.—Your lighting arrangement would necessitate a very long exposure, the lamp at 12 feet distance giving very little light. Why not use all reflected light? Marion and Co. made an apparatus on the principle, and it answered very well. The arcs were 6 or 7 ft. from sitter.

J. D.—We are sorry we do not know the maker using the monogram J. X. S. At the request of one of the leading dealers in secondhand lenses, we tried to identify this mark some time ago but without success. Probably it is one of the French makers, or more likely dealers, who were in business 20 or 30 years ago.

P. M.—Plaster figures (busts) are sold by Messrs. D. Brucciani & Co., 254, Goswell Road, London, E.C.1. There is no journal which deals specially with portraiture, although the subject is treated among general art matters in the "Studio," 44, Leicester Square, London, W.C.2, price 2s. monthly; and in "Drawing," 34, Paternoster Row, London, E.C.1, price 1s. monthly.

F. G.—We have found the ordinary dry-mounting, using a flat iron instead of a press, to answer very well with *stout* satin, the shellac might come through the silk; the best way would be to try a waste piece. We have also used Seccotine spread *upon the mount* and allowed to get tacky before laying down the silk to be quite satisfactory. You must not apply any mountant direct to the silk.

A. W.—What you want is optically impossible unless you stop down the lens to a very small aperture. In order to get constant focus with alteration of the distance of the lens from the sitter you would have to stop down probably to f/64, or smaller in the case of a lens of, say, 12 inches focal length, which would mean that you would have to give about 250 times the exposure, compared with the full aperture of, say, f/4.

A. B.—The cinematograph trade is at present not in a very organised state as regards purchasing films of local subjects. At present one market, and perhaps the chief one, is the cinemas in the district, but the proprietors of these require educating in order to convince them that there is a demand on the part of the public for local films. You will find some hints on this subject in an article in the "B.J." of October 8 last.

J. A.—The Series V. Cooke lens is of f/8 aperture, and for a lens of the focal length (18 ins.) for a 15 × 12 plate that is quite as large an aperture as is required. In almost every case you cannot do with a larger aperture, otherwise you will not get sufficient depth of focus. The lens is an excellent one for all-round outdoor work, such as architecture, machinery, and landscape, and for 15 × 12 plates you cannot have a better instrument.

S. W. H.—Dark blue or green are the best colours for studio blinds. If these are of the roller-blind form you must use blue holland, but if festoon curtains, sateen, or, better still, a casement cloth, is suitable. If you do not object to the extra cost Bolton sheeting, which is made for long window curtains, is more durable and stops out the light more effectually. Any

furnishing draper will supply all these materials. In London Thomas Wallis and Co., of Holborn, keep a good stock.

P. B. J.—The speckled appearance of the face is due to dust which has settled on the medium while it was tacky. Clean off the retouching and try again. The flatness of the enlargement may be due to slight over-exposure, or perhaps to diffused light escaping from the enlarging lantern. As far as our experience goes there is nothing to choose between glass negatives and films for enlarging. Films are more likely to be scratched and the scratches will show. Your prints are of a good colour, and we do not think you would gain anything by changing the developer.

W. M.—If the young lady were employed in premises into which your customers come, we think she would be a shop assistant according to the Shops Act, and would, of course, also come under the National Insurance Act. As regards remuneration, there is no usual custom, but from what we gather during the last year of two, at any rate, it is unusual to take a pupil, even without premium, unless some weekly payment is made to him or her. That is certainly so in London, where it is recognised that a youth or girl does a certain amount of useful work, even from the beginning.

J. W.—(1) Paper sensitised with a formula such as you mention keeps in good condition only for a few days, say a week or ten days at the outside. (2) The results are of quite a good degree of permanence; you may take it that they would last for ten or twenty years with scarcely any alteration. (3) We do not think the formula is any better than that in the "Almanac"; we know copper sulphate is sometimes included in such formulæ, but we do not think it is of the slightest advantage. (4) Yes, your formula ought to suit salted paper, but in that case we would sooner leave out the copper sulphate.

O. B.—The most permanent method of toning transparencies to a brown colour is by the ordinary sulphide method. Some lantern plates will tone excellently by this method, whilst others will not; you will have to try one or two plates. But every lantern plate that we have tried tones satisfactorily by the copper method, and the results of this latter are reasonably permanent. Certainly the transparencies should be varnished, preferably with a cold celluloid varnish, which itself gives a high degree of protection, and the binding strips should also be varnished. The celluloid varnish can be used also for this. An important point is to have the plates thoroughly dry before varnishing or binding by leaving them exposed for a few hours at a quite perceptible degree of heat.

A. W.—You do not give us sufficiently clear particulars to enable us to answer your questions. For a studio of such a short length as 13 ft. you are very much limited as regards the focal length of lens. For a full-length post-card portrait you could not use a longer focus than 7 inches, so that if you wish such a lens to cover a whole-plate, it would have to be stopped down to something like $f/22$ or $f/32$, and even then there are comparatively few lenses of this focus which would cover a whole-plate to the edges. In the circumstances, the best thing we can do is to refer you to the table in the "Almanac," showing the focal length of lens permissible for different classes of work. For your purpose it would be sufficient, we think, to base your calculations on a studio of 14 ft. length.

W. B.—Removal of ink stains is rather a hopeless business, and, unfortunately, you do not tell us what kind of print the photograph is. If it is any kind of silver print (bromide, etc.), almost anything which will remove the ink stain will also bleach the image. You had better try a little solution of oxalic acid, or the so-called salts of lemon. If this has no effect, you may be able to remove the stain with a decoction of bleaching powder, but you must go very carefully, otherwise you will destroy the image of the photograph. Usually the only thing which can be done is to make a copy of the photograph through a light-filter and on an orthochromatic plate, according to a method for which you will find full instructions in a little manual on the use of panchromatic plates issued by the Wratten Division of Kodak, Ltd.

A. C.—We suppose the plate-holder is of the single pattern with a metal shutter, in which case it is somewhat difficult to account for the occasional band of insensitiveness across the plate. It does sometimes happen that the varnish on the holder shutter causes insensitiveness, though we cannot recollect ever having had that in the case of a single metal plate-holder. It is possible that the shutter of the holder is bent, and in certain circumstances causes abrasion of the emulsion surface. Such abrasion is very erratic in its effects, but it may at times cause a certain degree of insensitiveness, and the greater or lesser time during which the plate is in the holder may perhaps account for the spasmodic appearance of the defect. We are afraid this is not a very good diagnosis of your difficulty, but it is the best we can do from the particulars you give us.

P. E. B.—(1) The Wothlytype is an old and now obsolete process of printing by means of a sensitising solution consisting of uranium nitrate and platinum chloride (or silver nitrate) dissolved in alcohol or in collodion. Working details are too long for quotation here, but you will find them fully set forth in "Photographic Reproduction Processes," by P. C. Duchochois, published by Hampton and Co., Cursitor Street, London, E.C. We do not know that this process has been used for printing on wood blocks, although it is of a kind suitable for that purpose. But is is more complicated and no better than the formulæ for printing on wood given in the article which appeared in the "B.J." of August 8, 1919. (2) This question also involves a lengthy answer; you should get the text-book, "Photographic Enamels," by R. d'Heliocourt, on processes of making photographic enamels, published by Messrs. Iliffe, 20, Tudor Street, London, E.C., price 2s. (3) You should be able to obtain all the chemicals for this process from Messrs. Johnson and Sons, 23, Cross Street, Finsbury, London, E.C.

W. B.—Metol-hydroquinone has been little used for the Antochrome process, and, so far as we know, has never been officially recommended by MM. Lumière. But the following is a formula for the first developer strongly recommended some six or seven years ago by Mr. A. B. Hitchins, now chief chemist of the Ansco Company, in America:—

For the first development, Solution A.

Water	1,000 c.c.s.
Metol	6.5 gms.
Soda sulphite (anhydrous)	40 gms.
Hydroquinone	2.10 gms.
Potassium bromide	2.5 gms.
Hyposulphite of soda	0.10 gms.
Ammonia, 0.880	20 c.c.s.

For use, one part developer, one part water. We have never used it, and we should rather fight shy of introducing even the small quatity of hypo into the MQ developer; although we know that hypo can be added in a very small dose without ill effects.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3169. Vol. LXVIII. FRIDAY, JANUARY 28, 1921. Price Fourpence.

Contents.

SUMMARY.

Mr. W. E. A. Drinkwater, in a contributed article, describes the results of practice in the design of a box printer capable of dealing with extreme conditions in respect to density of the negative and sensitiveness of the printing paper; also as regards meeting the practical conditions which arise through the necessity of giving different degrees of exposure to parts of the same negative. (P. 49.)

In a leading article the process recently published by Mr. J. I. Crabtree for the production of reversed dye images by the action of an acid fixing bath is reviewed in reference to the provisional trial of it which has been possible. Emphasis is laid on the need of a vigorous negative or positive, and on the avoidance of any treatment which adds a mordanting material to the image. (P. 46.)

The Northern exhibition, now on view at the Walker Art Gallery, Liverpool, contains in the pictorial section a large collection of work excellently representative of the present achievement in this branch of photography. (P. 47.)

The lectures to be delivered during the remaining period of the exhibition are announced on page 51.

Monday next, the 31st inst., is the latest day for the receipt of entry forms for the Scottish Salon, which opens at Dundee on February 19. (P. 45.)

Although photographs are rarely accepted as legal evidence in this country, prominent use was made of them recently in an appeal case turning on the navigation of two vessels which collided. (P. 57.)

In the United States schools of various kinds provide business for the photographer upon a much larger and creditable scale than is common in this country. (P. 46.)

British Chambers of Commerce in China are pressing upon the Chinese Government the need of adequate copyright protection in that country. (P. 45.)

Nominations of officers for the Council of the Professional Photographers' Association will be found in the report on page 56.

Mr. Alfred Watkins, in a further letter on factorial development, says that he would like to see other experimenters, and particularly the plate and developer makers, making measurements of the factors of developers. (P. 58.)

We regret to record the death of Dr. E. J. Spitta, well known for his writings on microscopy and photo-micrography. (P. 21.)

The construction of a vertical enlarging and copying apparatus is the subject of detailed description in a recent patent specification. (P. 52.)

A new invention in telegraphy is announced by which, so it is stated, drawings and photographs may be telegraphed. (P. 57.)

EX CATHEDRA.

The Scottish Salon. After the Northern, the Scottish Salon, which opens at the Victoria Art Galleries, Dundee, on Saturday, February 19. We would remind intending exhibitors that Monday next, the 31st inst., is the latest day for the receipt of entry forms by the hon. secretary of the Salon, Mr. James Slater, Rosemount, Camphill Road, Broughty Ferry. The exhibits themselves are given a further week's grace; they are required to be delivered at the Victoria Art Galleries on Tuesday, February 8. Unlike some current exhibition organisers, those of the Scottish Salon ask that exhibits should be both mounted and framed, but the framing may be in the passe-partout style. The glazing of prints is optional, but if they are not glazed, pictures and any multiple mounts must be wholly, not partially, attached to the back board. We understand that the forces within the Scottish Photographic Federation are being concentrated upon the Salon, and that the board of selection, which consists of Messrs. J. M. Whitehead, Dan Dunlop and W. C. S. Fergusson, is already assured of having to deal with a large entry, comprising much notable work.

* * *

Copyright in China. A recent conference of associated British Chambers of Commerce in China recently passed a resolution supporting further representations to the Chinese Government with a view to securing the latter's adhesion to the International Copyright Union. At present authors of literary or artistic works, including photographs, obtain no protection in China. It is true that China has some kind of Act whereby her own nationals may register their copyrights with the Minister of the Interior, but apparently no protection is afforded under this "Act" to foreign owners of copyrights. Although both England and the United States have entered into treaties with China for the establishment of reciprocal copyright protection, it appears that so far as China was concerned the regulations proved to be vague and unsatisfactory and quickly fell into disuse. It is pointed out that by the Shanghai treaty of 1902 China specifically undertook to provide protection for trade marks and copyrights by enacting laws to that end, but as the result of a sublime indifference to steps giving practical shape to that provision of the treaty, there is still no effective means of protection of literary and artistic works as regards copyright within Chinese dominions. The Chambers of Commerce are evidently right in their view that the addition of China to the countries subscribing to the Berne Convention is the only step which can be expected to place the copyright question on a sound basis. That would define owners' rights in artistic and literary works clearly; the genius of the Celestial official for circuitous legislative methods would be defeated, and foreigners' rights of reproduction should be more easily enforced.

Prints for Reproduction. There are still many photographers, both in portraiture and commercial work, who are under the impression that a brilliant, somewhat hard print is necessary to obtain the best results in half-tone work, and as they never come into direct communication with the process operator they have no means of learning that they are in error. The modern process man will tell you that for high-class blocks he prefers a soft print full of gradation, but free from flatness. In the making of the screen negative and in the various stages of etching he can introduce high-lights into a rather soft subject, but he cannot produce detail in harsh lights and shadows. If the original negatives are on the hard side, full exposure and the use of a diluted developer will give the most useful prints. For reproduction, the colour of the developed image is of little account. A rusty black, due to short or weakened development, will often reproduce as well as a pure black tone. Sepia-toned prints should never be submitted for reproduction, as the shadow detail can hardly be preserved in the block. Purple-toned P.O.P. was at one time considered as the only suitable medium, but glossy or carbon surface bromides now seem to be preferred.

* * *

School Work. In this country school photography generally consists in taking groups of children at the elementary schools and the sale of post-cards at a very cheap rate. In America it is regarded in quite a different light and good class studios make a special feature of it. There, it is the custom to cater for the students at the various grades of colleges, boarding schools, and what would correspond to the high schools and county schools of this country. It appears to be quite a custom for students to exchange portraits at the termination of their term and sometimes on other occasions. Special styles and sizes at moderate but fair prices are reserved for school work, and these are not shown to ordinary sitters. In some instances the mounts are specially printed with the name of the school and the year of production, college emblems or colours being used, if desired. There is quite keen competition for this work, the orders being placed by a committee of students after inspecting specimens submitted by rival firms. Groups, sports pictures, and the like, as well as views of the school buildings, also come in the way of the official school photographer. Something of the sort should be possible here in towns near large schools.

* * *

Old Lenses and Spherical Aberration. In these days of high prices we hear of many photographers who are tempted to purchase an old-fashioned long focus R.R. lens, using only the centre of its field in preference to paying the higher price for a first-class anastigmat. Quite apart from the wisdom or unwisdom of this, there is, however, one caution that should be given to the user of one of the older R.R. lenses, if he would avoid unsharp negatives, by reason of the lens being uncorrected for spherical aberration; that is to say, the peculiarity of some of these instruments often being of different focus at different stops. The older photographer used to lenses of pre-anastigmat days, will doubtless be fully aware of this, but the warning is necessary to those whose experience has been limited to the more modern, well-corrected instrument. When using an untried R.R. lens, particularly if of an old pattern, the image upon the ground glass should be carefully examined with the stop that is to be used when making the exposure in position, since the alteration of the stop may have the effect of making a previously sharp image decidedly unsharp. Nor is lack of correction for spherical aberration entirely confined to the older R.R. instruments, for we have found it present in a lesser degree with some cheap instruments of more recent manufacture. Modern workers are so unused to looking at the effect of stopping down, in affecting the sharpness of the image adversely, that a caution in the matter is not out of place.

REVERSED DYE IMAGES.

The obvious importance of the method of producing reversed dye images, outlined in the communication by J. I. Crabtree which appeared in our last issue, justifies a further reference to the subject. Whilst it cannot be denied that the process, if it can be successfully applied on the large scale, will be of intrinsic value in colour cinematography, it is as well to realise that the production of perfect results is not at present an easy matter. The details given in the text of the communication are sufficiently explicit to encourage experimentation on the part of others, but there are several minor pitfalls in the process which should be brought to the notice of those interested. Some of the difficulties are called attention to in the text, and it will be found that success can only be attained by strict adherence to the stipulated conditions of manipulation. For reasons which will appear later, it is not sufficient to compound the solutions in the all too frequent rough and ready manner adopted by the average photographer, and the plate or film which it is sought to convert into a reversed dye picture must be the product of straight, clean work. The following conclusions have been arrived at as the result of experiments made under various conditions with different types of negatives and dyes representative of the different classes used industrially.

The negative (or positive) should be of the decidedly vigorous order, developed well through the body of the emulsion, and if on film, the "anti-curling" gelatine should be stripped from the back before commencing operations. The use of a combined hardening-fixing bath is to be deprecated, and the image must not have been toned or intensified by any process which adds a mordanting material thereto, *e.g.*, the chromium or copper intensification processes. It is not stated in the communication whether operations were commenced on a dry or previously wetted film, a point which was found to be of some importance, as was also that of the age of the film. Given a freshly-prepared negative of the very plucky type, which has been thoroughly fixed in a *plain* hypo bath, the so-called "separate" process in which the staining and the reduction (or bleaching) of the dye are effected in separate baths, may be made to give presentable reversed dye images; if, on the other hand, the previous history of the negative is unknown, only the super-optimist will expect perfect results.

The dyes recommended in the communication are of the basic type and such as readily reduce to the leuco state. These dyes are difficult to handle, even when using distilled water, and if only a "hard" alkaline water is available, the alkalinity of such water causes a precipitation of the dye, and then the bath can only be got into the correct condition by the very cautious addition of acetic acid. Again, if the water employed for the washing after the "bleaching" contains much dissolved air, the so-called leuco reduction product is only partly removed, a proportion of it being re-oxidised to the dye. In fact, this re-oxidation of the leuco derivative to the dye constitutes, in the writer's opinion, the weakest feature of the process—even taking into consideration the finesse which must be exercised in the bleaching opera-

tion. In the hope of making the destruction of the dye more permanent, experiments were made with dyes, the reduction products of which are perfectly stable against atmospheric oxidation, with most promising results. Whether in this work the nature of the gelatine or of the image gave material assistance which was lacking in the experiments with basic dyes it is difficult to say, but the results obtained were superior to those obtained with the latter class of dyes.

If it may be taken as a fact that dyes other than those which form leuco derivatives can be employed in the process, it may be concluded that the reducing power of the mixed acid hypo bath is of a very much higher order than was previously imagined—it is comparable, in fact, with that of a solution of sodium hydrosulphite, and this latter substance is one of the most powerful reducing agents known to chemists. It is very difficult to understand how the bleaching action can arise from nascent sulphur, for if that substance were the active agent, one would expect a sulphide toning effect with any and every acid fixing bath; in fact, the undeveloped silver bromide of every negative and print put into such a fixing bath would be immediately "toned." Fortunately, such an undesirable impasse does not occur.

If, however, the chemical elements present in hypo, when its aqueous solution is faintly acid, can re-arrange themselves in such a way that they form a new compound analogous to or identical with sodium hydrosulphite, marked bleaching propensities would be characteristic of such faintly acid solutions. As is pointed out in the communication, there is a general reducing action throughout the solution, and the function of the silver image appears to consist solely in catalysing the reaction and so hastening it in the local areas contiguous to the image. A very simple experiment will show the bleaching power of an acid fixing bath on methylene blue:—

If about half an ounce of a 1:1,000 aqueous solution of the dye be divided into two equal portions in test-tubes, and to one portion be added a crystal or two of hypo and then a few drops of "acid hardener," the contents of the other tube being diluted with water to keep the volumes approximately equal, it will be found, on slightly warming (avoiding shaking) and allowing to stand, that the colour of the solution is discharged in the one case, whilst the plain aqueous solution remains unaltered. The results of this experiment clearly rule out of court any necessity for specific chemical action on the part of silver, and it is difficult to account for Mr. Crabtree's statement that the dye is only reduced by an acid fixing bath in the presence of silver. It may be admitted at once that the presence of finely divided silver very considerably hastens the bleaching action, but in so doing it affords unmistakable evidence that its action is not strictly chemical; the silver in this case is merely a catalyst, and is itself unaltered by the reaction.

We are thus thrown back for an explanation of the reduction process to the similarity between hypo and sodium hydrosulphite, and one regrets that the subject, although of absorbing interest to chemists, is not one which comes within the scope of such notes as these. Beyond mentioning the fact that some authorities hold the view that hypo is a decomposition product of sodium hydrosulphite we must leave the matter for chemists to decide. Sufficient has been said to indicate that such communications as Mr. Crabtree's open up a wide field of research, the cultivation of which will lead to a harvest of facts, valuable alike for the practical service they will render in our branch of industry and for the better understanding they will give us of the intricate workings of those substances which we at present employ all too empirically.

R. E. C.

THE NORTHERN EXHIBITION.

With civic honours the eighth Northern exhibition opened on Saturday last at the Walker Art Gallery, Liverpool. The occasion was a notable one, for it marks the revival of the courageous policy of bringing together a great photographic collection which was inaugurated in 1901 by the late C. F. Inston, to whose enterprise and assiduous labours a deserved tribute is paid in a prefatory note to the catalogue. The war naturally disturbed the aims of our friends in Liverpool and Manchester to make a northern exhibition an annual event, but Liverpool has now again taken the initiative, and has placed upon the walls of the Walker Art Gallery a collection which admirably represents the current achievement in pictorial photography, and, moreover, does not overlook some of the fields in which the technical and scientific photographer is doing notable work. Also, the trade and manufacturing side of photography is brought to the notice of visitors by the inclusion of a number of commercial exhibits. Photographers in the north have, therefore, every reason to visit Liverpool during the period of the exhibition, that is to say, until February 5 next.

The hanging committee have made good use of the spacious and well lighted walls at their disposal, and, as far as possible, have arranged the work of each notable exhibitor in a group by itself, with the result of facilitating the study of present tendencies among the pictorial workers in a way which is impossible when exigencies of space impose the necessity of a closer scheme of hanging.

In the scientific sections a valuable contribution is that by members of the Photomicrographic Society, whilst X-ray technique and industrial usefulness obtains its representation by the exhibits of Mr. N. E. Luboshez and Messrs. W. Watson & Sons (Electro-Medical), Ltd. Mr. Banfield's remarkable photographically recorded curves obtained by the "Ratiograph" appear also, after having been shown at the last Royal exhibition, and at Liverpool fortunately are correctly catalogued. When it is added that there is a large collection of colour transparencies, mostly Autochromes, of which we hope to speak in a subsequent issue, it will be seen that the Northern approaches photography from a comprehensive number of standpoints.

In the pictorial section the awards were as follows:—

Plaques.—H. G. Allen, "The Mackerel Net" (No. 29); Arthur W. Burgess, "Romantique" (No. 266); Robert Chalmers, "Margery" (No. 222); C. Kendall, "Dockers" (No. 365); Herbert Lambert, "Madeleine" (No. 121); J. Harold Leighton, "The Old Church" (No. 101); John MacSymon, "September Morning" (No. 42); G. F. Prior, "April Sunshine, Pump Court" (No. 213); Rabinovitch, "In the Spirit of Old Granada" (No. 94); James Rowaft, "High Tide" (No. 168); Hugo Van Wadenoyen, Junr., "Early Closing Day" (No. 158).

Honourable Mention. Charles A. Allen, "The Sentinel" (No. 5); Paul L. Anderson, "Early Morning in the Hills" (No. 50); Arthur W. Burgess, "At Chester" (No. 273); F. G. Curson, "Frank Forbes-Robertson" (No. 294); Louis Fleckenstein, "Amazon" (No. 306); Rev. J. V. Haswell, "Arabesque" (No. 225); Herbert Lambert, "Frank Forbes-Robertson" (No. 124); J. Arthur Lomax, "Sunlit" (No. 135);

N. E. Luboshez. "Study" (No. 337); F. Marx. "Rapids" (No. 350); Eng.-Com. Mowlam, R.N., "The Suspect" (No. 248); Newton C. Owen, "Egypt" (No. 82); Rabinovitch, "Girl in Black" (No. 95); R. Shepherd, "The Windlass" (No. 12); Louis J. Steele, "A Venetian Study" (No. 236); Hugo Van Wadenoyen, Junr., "Mark Stanley, Esq." (No. 159); Lionel Wood, "Liliane Gilbert" (No. 282).

The following were the awards for colour transparencies and lantern slides:—

Colour Transparencies.—Plaque: Henry Irving (No. 325).

Honourable Mention.—Henry Irving (No. 377); N. E. Luboshez (No. 322); F. R. Newens (No. 279); Louis J. Steele (Nos. 372 and 375); J. C. Warburg (No. 339).

Lantern Slides.—Plaque: James Shaw (No. 117).

Honourable Mention.—Herbert Felton (No. 36); Robert Chalmers (No. 44).

These general notes will, we hope, suffice to give an adequate impression of the importance and wide scope of the exhibition. Naturally, chief interest ranged round the pictorial section, a series of critical notes on which, by a Liverpool correspondent, appears below.

THE PICTORIAL SECTION.

Among the works which receive prominent display in panels on the walls are those of Arthur F. Burgess, Nos, 266 to 273. Though rather small in size, they are of exquisite delicacy. Mr. Burgess deservedly receives a plaque for his "Romantique" and an honourable mention for "At Chester" (No. 273). His well-known "Shambles, York" (No. 269), is one of this outstanding series.

In a group by Van Wadenoyen, Nos. 157 and 158 are conspicuous; the latter, "Early Closing Day," has the true touch of genius. His portrait work is not better than is expected from him.

"The Spirit of the Hills" (No. 4), by Charles A. Allen, is rich in quality and a fine composition. In "The Night Catch" (No. 9), W. L. G. Bennett has a dramatic note well conveyed. In No. 10 W. H. Marquis has a successful rendering of a peaceful scene. No. 12, "The Windlass," is the best of the exhibit by R. Shepherd, and is a bold, well-handled piece. His portrait of the Rev. J. Oldham (No. 13) is the best of his studio work.

"The Shipyard" (No. 20), by George Good, is modern in feeling and skilfully handled. The sky gradation is particularly pleasing. In No. 21 Rev. J. W. Isherwood has an unusually good study of an old subject, which he calls "Greeting the Dawn." Of the group by H. G. Allen, No. 31, "The White Tower," is outstanding and a notable work in transfer. No. 30 is an ordinary scene transformed by a flood of beautiful light. The composition, however, is not entirely satisfactory. "The Mackerel Net," No. 29, by the same worker, is well composed and pleasing in value; it receives a plaque. No. 36 is a pleasing study of water plants by T. Sweatman. The work of John MacSymon, Nos. 38 to 43, makes a good display, Nos. 41 and 42 being the best. the latter of painter-like breadth.

No. 38, "A Humber Squall," is a fine cloud piece with a low horizon. Nos. 47/8, by H. J. Summons, show a strong decorative sense. Four works by F. O. Libby are shown, No. 52, "The Spirit of the Winds," being a well handled study of the nude, and No. 53 a frieze-like design. Three gum prints, Nos. 57/8 and 76, by Herbert Bairstow, are of beautiful texture. No. 50, by Paul L. Anderson, has a delicate beauty and thorough artistry. A nude study, No. 56, by Arthur C. Miller, is of a high order of merit. Of Arthur C. Banfield's work. No. 68, "Portrait of T. H. B. Scott, Esq.," is perhaps the best.

Of four works by William Gordon Shields, No. 70 is the best; in No. 73 the strong colour is unwelcome. No. 79A is by a South African worker, J. C. Stick, and is a good study of a boy's head. No. 82, by Newton C. Owen, is a beautifully textured print; in No. 81, by the same worker, the sky might, with advantage, be toned down. A. Benson Ray shows an unusually successful still life in No 87.

In No. 90 John P. Oakes has an excellent transcription of a pleasing scene. "A Liverpool Dock," No. 89, by W. H. Gleave, is well seen, but suffers from lack of quality in the print. Nos. 93 to 95, by Rabinovitch, are prints of remarkable merit; No. 95, "Girl in Black," rises far above the average of portrait work. "Coal Barges on the Thames," No. 96, by C. Upton Cooke, is a magnificent piece of work and a fine composition. Six prints by J. Harold Leighton are of unequal merit; Nos. 101 and 105 are the best, the former receiving a plaque. No. 108, a small study of a steam-crane, by H. E. Johnson, is very well handled. Of J. C. Warburg's four prints No. 109, an old favourite, "Saltburn Sands," is still the best. No. 114. "Ann." by Ethel Eadon, is an engaging child study and rich in quality.

Of seven fine prints by Herbert Lambert, Nos. 119/25, the best is probably "Dierdre," which scores by its simplicity and arrangement. "A Sylvan Glade," No. 132, by T. Shovelton, is beautifully soft and luminous. A beautiful set by J. Arthur Lomax, Nos. 135-140, contains some of the most striking work in the Exhibition; of these Nos. 137 and 139, "July, 1920," and "Sun Splash," show the most perfect artistry." "The Confession," No. 144, by Walter Lee, is very pleasing and restrained. In "Doves' Place," No. 146, M. O. Dell has a striking work, highly original in conception. It is not, however quite successful, being too harsh and generally it is too cold. "A Southdown Mill," No. 150, by A. Hanson, is pleasing, and "In the Evening Sunlight," No. 152, by the same worker, is luminous and warm. Of four prints by E. Howard Burnett, "Le Chapeau Neuf," No. 164, is the best; No. 165 is of rich quality. "High Tide," No. 168, by James Rowatt, is well composed and has a pleasing texture. In No. 172, "Nude Study," Mrs. Florence Wild has a child study of the popular type but quite good. Robert M. Blackburn's "Riverside, Worcester," No. 178, is of pleasing luminosity, with the composition rather too central. "Industry and Grime," No. 180, is by J. J. Phelps, and is a broadly and well handled rendering of an old subject; the same remark applies to No. 181, by the same worker. No. 167, "Portrait of Hugo Van Wadenoyen," by M. Rodway Leeming, is a forceful presentation

"The Shadow," No. 189, by T. J. Lewis, is well seen and well handled, but No. 188, "The Eternal Triangle," by the same worker, is childish and only redeemed by the clever lighting. "Waterloo Place," No. 192, by A. C. Banfield, has all the qualities of a steel engraving. Dignity and reserve characterise No. 196, "A Portrait," by Mrs. C. A. F. Gash. Nos. 205/6, by E. M. Borrenbergen, are good landscapes but printed in an entirely unsuitable colour. "Loaded," No. 207, by A. G. Lever, is a well considered dock study but lacking in strength. "The Granite Stairway," No. 210, by E. Tinker, is a striking composition, but the subject is presented too candidly.

A very fine group is furnished by G. F. Prior, Nos. 213 to 217, of which No. 213, "April Sunshine, Pump Court," is the best, with No. 217 following closely. Of six studio prints by Robert Chalmers, the best is the Greuze-like "Helen," No. 223. No. 227, "Lunch for Six," by Rev. J. V. Haswell, would be a suitable design for a nursery frieze, the sense of repetition being very pleasing. Nos. 278 and 282, by Lionel Wood, are of high merit, the latter, "Liliane Gilbert," receives an honourable mention. No. 233, "Evening, After the Storm," by Justin McCarthy, is a strong picture of good quality and composition. No. 239, by Louis J. Steele, lacks quality, and his three other prints, Nos. 236 to 238, are not notable. Basil Schon has a charming design in No. 245, "The Cedar Branch," and an old favourite in No. 244, "Midnight." No. 247, E. J. Mowlam, is an unhappy composition, and No. 248, "The Suspect," by the same worker, relies upon its title for

interest; however, it receives honourable mention. In No. 249, "Snow on the Upland," H. B. Bradley shows a print well worth close inspection; it is strikingly designed and well handled. No. 251, "The Bathing Pool," by S. Grimshaw, is of the Barbizon type, and very good. In No. 252 Herbert Felton gives us a very interesting picture, "Into the Light," in which curious reflections play a prominent part. Nos. 255 and 256, by Bertram Cox, are particularly luminous. No. 258, "Evening After Rain," being of fine quality. No. 259, "From Behind the Scenes," by R. Caudwell, is of the snapshot type, but is unusually happy; probably this subject has never been better done. C. R. Dixon, in No. 265, "Three Fishers Went Sailing," has a pleasing arrangement of values. No. 275, by Captain Ashbee, is a forceful presentation of the Taj-Mahal, and is good work. No. 286, "To the Station," by Gladys Openshaw, is an exceedingly clever picture made from very ordinary material. In No. 287, "A Farm Road, Anglesey," by Jas. Shaw, the open air feeling is good, but the composition is too central. No. 289, "The Sands of Pleasure," by the same worker, is a happy exercise in the nude, but not too well executed. In the group by F. G. Curson, No. 292, "Portrait of Matheson Lang," is easily the best, and, of course, owes a good deal to the sitter. In Nos. 297 to 299, Alex. Keighley displays his accustomed artistry and sense of romantic feeling. Of five powerful prints by Aage Remfeldt, Nos. 300 to 304, No. 300, "Miss Holm," is the best. Louis Fleckenstein's "Amazon," No. 306, is a beautiful work; but his two other prints in this section suffer from lack of concentration. No. 309, by Thos. A. Sheckell, is a good picture of the silhouette type; and No. 310, by the same worker, is extremely pleasing. No. 312 is a fine head study by Angus Basil. No. 314, "Sheep," by S. de Janieski, is notably sunny; while No. 315, "The Summer Time of Life," by A. H. Green, does not suggest summer time in the least. "The Dreamer," No. 316, by Arthur C. Miller, is good, but the two nude studies by the same worker are not at all convincing. "Outward Bound," No. 319, by Don Fitts, is highly imaginative. Nos. 322 to 324 are three fine prints by Sophie L. Lauffer, characterised by originality in outlook and quality in execution. Nos. 326 and 327, two portraits by Mrs. Whitaker, are good examples of her work. W. F. T. Pinkney's "My Lady of the Manor," No. 329, has an old-fashioned and sun-flecked charm. "Winter Landscape," No. 331, by E. Wragg, is simple and convincing. Six powerful portraits by N. E. Luboshez are grouped, Nos. 332 to 337, of which Drs. Kenneth Mees and Thurstan Holland are particularly well rendered. Two striking night photographs, Nos. 338 and 340, are by Wm. A. Alcock; No. 351, by the same worker, is rich in quality. In No. 342 the Rev. J. Oldham shows dexterity in handling. No. 344, "Silhouettes," by T. D. Ralli, is unconventional and quite successful. In No. 358, "A Winter Morning," the same worker reduces the incident to the minimum, but the print is thoroughly artistic. "Karsavina," No. 346, by Arthur C. Banfield, is a clever study. No. 357, "A Summer's Day," by John Chapman, is very sunny, but the figure is awkward. Six large transfers by C. Kendall, Nos. 361 to 366, are boldly handled. Nos. 364 and 366 are the most original, but No. 365, "Dockers," receives the plaque.

Colour bromoils and gum prints by Louis Fleckenstein, George Hickerley and J. West Lang make up a screen panel, Nos. 377 to 383.

The best of Fred Judge's colour transfers is No. 371, and is an extraordinarily beautiful piece of work. No. 372, perhaps, is too ambitious, and fails through lack of concentration. No. 375, a colour gum print, by Max Albert, is a well rendered head of an old man.

As a contrast to the modern work displayed on the walls, the work of D. O. Hill is shown on screens. Though, no doubt, wonderful work in its period, it undoubtedly suffers in the comparison. The originals of "Photograms of the Year" occupy considerable wall space, and though as a whole a fine collection there are serious lapses—chiefly in the foreign work.

AN IMPROVED BOX PRINTER.

The transition from print-out papers, dependent upon daylight, to the now almost universal development papers, exposed by artificial light, has carried us, naturally, from the old-fashioned pressure frame to the printing box. The writer has always been a great advocate of the more modern labour-saving contrivance; in fact, he believes he was the first to use a box-enclosed light with which the act of applying pressure automatically made the exposure. About 1903 he was using a great quantity of Velox paper, and he had made for him a box containing a Nernst lamp screened by a shutter of yellow fabric. In this early device the negative was laid on the glass top of the printing box, and the sensitive paper adjusted by the yellow light so obtained. Exposure was made by closing the hinged lid of the box, which simultaneously brought about contact between paper and negative and removed the yellow fabric shutter; exposure continued so long as the lid remained closed, whilst lifting the lid restored the yellow fabric shutter to its original position, thus terminating the exposure. It was very soon realised that with the quicker bromide paper an ordinary electric glow-lamp was quite adequate for exposure. The Nernst lamp, whilst giving a very strong white light, needed to be kept burning when once alight—hence the yellow shutter. The glow-lamp, on the contrary, could be switched on and off with ease; and so one did away with the yellow shutter, substituting a simple push-switch, which caused the lamp to glow by the pressure of the lid of the printing box.

This latter-mentioned device is the basis upon which all modern printing cabinets have been designed. Thinking the matter over carefully, it cannot be said that any great advance has since been made upon that principle. True, we have, additionally, strip-printer attachments, but these were the inevitable sequence once the idea of quick exposure and quick changing were mastered. Strip printers certainly make the printing box an even greater blessing than before; but they cannot be said to improve upon the principle of a box-enclosed illuminant actuated by the same operation which produces pressure contact. Actually, it is hard to see just where improvement could be made upon this idea, which combines speed with efficiency in so marked a degree.

Great as are the advantages of a box printer, still it has its drawbacks. It seems as if there were no powers of control over the exposure other than shortening or lengthening the period of contact. There are no means of locally intensifying or reducing the power of the light to overcome inequalities in opacity in various parts of the same negative, and this is a control that is at times very urgently needed. The limitation to altering the period of contact means that, whilst a thin negative may need only an exposure of 1 second, a very thick one may need a minute, or even more. Elaborate modern printing cabinets are now furnished with a battery of lamps for the purpose of reducing the exposure period when using slow-contact papers. With these there certainly is a power of local control over the light, but it is of a negative character; by removing one or more of the lamps from their sockets the thinner portions of a negative may be "kept back" because of the locally reduced light-action.

With these ideas in mind, it is suggested that a box printer

be constructed which, by altering the position of the single exposing lamp, will largely overcome both these difficulties.

Anyone who, like the writer, has to print from negatives from all sorts of sources, will welcome a means by which they may be reduced to a common level of exposure. It is the boast of one advertised strip printer that by means of it 1,000 prints per hour may be turned out. Now there are only 3,600 seconds in an hour, and if we calculate the time for shifting the strip from step to step as 5 seconds per strip (1 second between each exposure), and add 10 seconds for changing from one strip to another, we find that we have not much more than 1,000 seconds left for the actual exposures; it is evident, therefore, that to comply with the claims of the advertisement the negative and light in combination must be such as will require an exposure not exceeding a maximum of 1 second. The same lamp at the same distance would be fatal to speed with a thick negative and, with a thin negative, would be ungovernable, as it is almost impossible to calculate fractions of a second mentally, or to translate such mental calculations into deft movements of the hand. The suggestion here put forward is that a box be constructed so that a very powerful light may be used quite close enough to the printing bed to "get through" the thickest negative in 1 second, and which at the same time, by removing the source of light to the appropriate distance, will still allow a thin negative to receive the same actual period of contact (1 second) whilst the effective exposure is reduced to quite a small fraction. If we thus provide for our extreme negatives, it only remains to compute the intermediate distances for any negative lying within this range of opacities.

It is presumed that one second is the least period which can be mentally measured with ease and which at the same time does not impede speed; we therefore take it as our standard exposure. In computing the distances at which the lamp may be placed, we first of all have to consider how much at a time we should increase or decrease. A recent writer in this journal has suggested that an increase of 25 per cent. in exposure is the least that shows perceptible difference after development. Perhaps so; and yet it seems to the writer that with a somewhat smaller increase there is actually a slight increase in the depths of the shadows, even though there be no appreciable penetration in the high-lights. We propose, therefore, to consider an increase of about 20 per cent. To increase the period of exposure from 1 second to 1.2 seconds is not practicable, but to remove the lamp to the appropriate distance and still make a contact of 1 second presents no insuperable difficulty. The calculation is not so simple as seems at first sight. If we decrease the distance of the lamp by 20 per cent. we shall overstep our requirements, because the rule is that we must alter the distance in proportion to the square of the numbers, rather than in the proportion of the numbers themselves. The following table is worked out on the assumption that occasions will arise when, for special purposes (considered later), it will be useful to have the lamp so close to the negative as 2 in. The figures given in the table are not claimed to be mathematically correct, but it will be found that the table is so near to exactitude as to give all the necessary grades of differences in the resultant prints.

It will be seen from an examination of the table that an actual contact of 1 second at 2 in. distance will give an effective exposure equal to 128 seconds, as compared to an actual and effective exposure of 1 second at 23.5 in.; this range should provide for the varying opacities of most negatives. The writer's experience leads him to the conclusion that if the lamp used be a 100-c.p. half-watt lamp, then a contact of 1 second at 23.5 in. will meet the requirements of the thinnest negative that will give a print at all. An average portrait negative will probably be printed at about 11.3 in., resulting in an effective exposure of 4 seconds, whilst most landscape negatives will come within the range of distances 4 to 8 in., resulting in effective exposures of from 8 to 32 times our standard minimum.

Distance of lamp from negative in inches.	Equivalent exposures in seconds.		
	100 c.p.	40 c.p.	16 c.p.
2.	128.	51.	23.
2.2	107.5	43.	19.4

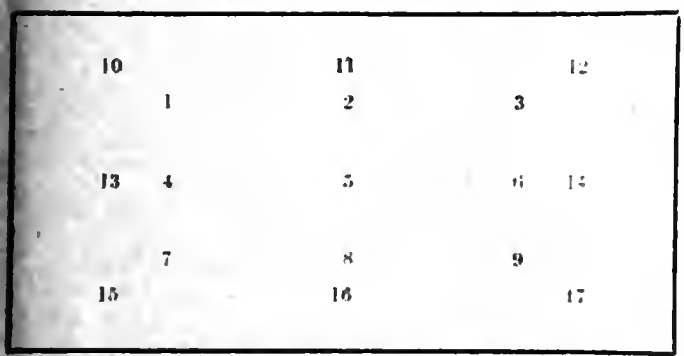
20.75	1.2	—	—
23.5	1.	—	—

It is a not infrequent occurrence to find a negative which from varying causes is unevenly illuminated. It may be that some very bright object in the centre is surrounded by darker objects, *e.g.*, a street scene with a dense vista in the centre and heavy buildings close at hand on either side. Such a negative seems to cry aloud for some means of concentrating the light on the centre and at the same time lowering the efficiency of the light at the edges. Now it is a well-known fact that if a lamp be placed at any less distance than 4 in. from a half-plate negative the illumination is feebler at the edges than in the middle, and so we utilise what would otherwise be regarded as a faulty lighting system to remedy a defect in such a negative as this by bringing the lamp quite close to the plate, even so close as 2 in. in some cases. But such a negative will rarely, if ever, need so great an exposure as 128 times the minimum; we shall be compelled, therefore, to lower the power of the lamp. The substitution of a 40-c.p. lamp (metal filament) for our 100-c.p. half-watt will make the effective exposures equal to 51, 43, 36.2, 30.4, 25.5, and 21.5 times the standard minimum at the six nearest positions, whilst the further exchange to a 16-c.p. carbon filament lamp makes the effective exposures equal to 23, 19.4, 16.2, 13.6, 11.5, and 9.7 times respectively at the same six distances. An alternative method of reducing the power of the light is to place in series with the lamp a variable resistance, by which means the 100-c.p. lamp is used all the time, and the power of the illuminant is reduced in steps as more resistance is brought into circuit. This is the ideal method, because of the simplicity of working; it is much quicker and easier to move the handle of the resistance a place or two as required than to open the box and exchange lamps.

But the patches of excessive opacity do not always occur in the centre of the plate—a street scene frequently has one side of the street in sunlight and the other in shadow, or overhanging trees may shade one side, in which case it becomes necessary to move the lamp to a fresh holder opposite the thicker side of the negative; a distant view with near foreground, or a plate with good clouds which will not "print up" will always be improved by removing the lamp to a fresh holder which is even beyond the edge of the negative, but still opposite the more opaque portion of it. Many road scenes taken in mid-summer give negatives in which the roadway is

abnormally dense, printing almost white, and rendering it practically impossible for a title to show against it: for such a plate the exact reverse proceeding to that adopted with the distant view is indicated.

With a lamp-holding board such as is shown in the diagram it is judged from actual commercial experience that every type of negative can be made the most of. Position 5, of course, represents the normal position for the lamp for normal negatives; positions 1, 2, 3, 4, 6, 7, 8 and 9 will then represent the relative positions for lampholders used when printing



with a lamp at either of the first three distances (2, 2.2, or 2.4 inches) in order to alter the illumination locally; and positions 10 to 17 represent the suggested relative positions when it is used at either of the next three distances (2.6, 2.8, or 3.1 inches). When printing postcards, the rectangle 1-3-7-9 is conveniently made about 7 x 5 inches, and the rectangle 10-12-15-17 can be 9 x 7 inches. The wiring for so many lampholders presents no real difficulties, although involving a little bit of labour. The respective sockets are wired in parallel, not in series; a convenient length of the flex or workshop cable is bared down to the wires, and a connection is made from the positive cable to one side of each socket, followed by a similar procedure with the negative cable to the other side of each socket; the two cables are then insulated from each other and strongly bound up with insulating tape. An alternative method is to have marked out positions 1 to 17 on the board that carries the lamp, which is then used always in the same lampholder but moved to the desired position before exposing.

It now remains to make an arrangement by which the different distances can be readily adjusted. If the lamp-holding board is regarded as a shelf with a sufficient play of flex it would be possible to arrange cleats on the inner walls of the printing box at those suitable distances which would bring the nearest portion of the glowing wire of the lamp to the required distances from the negative. This is scarcely practicable, however, unless the shelf is very thin indeed, because at the nearest distances the steps are but one-fifth of an inch apart. A better arrangement is the pulley and counterpoise method, which will allow of movement through quite small fractions of an inch; a tell-tale needle attached to one of the pulley ropes will at all times register against a carefully marked out scale placed within vision somewhere on the printing bench.

It is hoped that these suggestions, all of which are the result of commercial practice, may tend to enhance the utility of the bromide printing box. W. E. A. Drinkwater.

DEATH OF DR. E. J. SPITTA.

We regret to see the announcement of the death, at the age of 68, of Dr. E. J. Spitta, a former president of the Royal Microscopical Society and of the Quekett Club. Dr. Spitta, who at one time practised as a doctor, had made his home for many years at Hove, and had largely interested himself in local scientific and archæological pursuits. He was the author of several publications, but will perhaps be chiefly commemorated by his comprehensive works on the microscope and on photo micrography

NORTHERN PHOTOGRAPHIC EXHIBITION.

The following are the lectures to be given at 8 o'clock p.m. at the Walker Art Gallery, Liverpool, during the remaining period of the exhibition:—

January 28. "In Pursuit of a Shadow in the Tonga Islands," by the Rev. A. L. Cortie, S.J., F.R.A.S., F.Inst.P., Director of Stonyhurst College Observatory.

January 29. "The Natural History of Central Africa, with special reference to the Tsetse Flies and Sleeping Sickness," by Prof. Robert Newstead, F.R.S., etc.

January 31. "An Evening in Lakeland," being a reading of Wordsworth's "An Evening Walk," by Alexander Keighley, F.R.P.S.

February 1. "Wild Life in the Treetops," by Capt. C. W. R. Knight, M.C., F.R.P.S.

February 2. "The Open Road," by C. W. Budden, M.D.

February 3. "The Malay Archipelago," by Somers H. Ellis, M.I.C.E., F.R.G.S.

February 4. "Twixt Alp and Apennine," by J. Dudley Johnston.

February 5. "The Charm of the Hills," by W. W. F. Pullen, H.M.I.

FORTHCOMING EXHIBITIONS.

January 22 to February 5.—Northern Photographic Exhibition, Walker Art Gallery, Liverpool. Particulars from the Hon. Secretary, Liverpool Amateur Photographic Association, 9, Eberle Street, Liverpool.

January 27 to 29.—Birmingham Photographic Society. Particulars from the Hon. Secretary, Philip Docker, Birmingham Medical Institute, Edmund Street, Birmingham.

February 14 and 19.—Leicester and Leicestershire Photographic Society. Latest date for entries, February 5. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

February 19 to March 5.—Edinburgh Photographic Society. Latest date for entries February 10. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

February 19 to March 12.—Scottish Salon, Dundee. Latest date for entries, January 31. Particulars from the Hon. Secretary, James Slater, Rosemount, Camphill Road, Broughty Ferry.

March 16 to 19.—Hackney Photographic Society. Latest date for entries, March 1. Particulars from the Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 13 to 23.—Portsmouth Camera Club. Latest date for entries March 31. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Latest date for entries, March 17. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Latest date for entries, April 16. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs.

Manchester Amateur Photographic Society.—The annual report for the year 1920 shows the full series of weekly meetings maintained almost without intermission throughout the year. The Society has now 430 members, a net increase of 46 during the year. It is a sign of the great changes taking place in the membership of photographic societies that only this increase was obtained, although 110 new members were elected during the period. With the raising of the subscription from 7s. 6d. to £1 1s. the Society hopes to retain its increased membership by providing greater facilities than it has hitherto done, despite the much greater cost of almost every item of its expenditure.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, January 10 to 15 :

COLOUR PHOTOGRAPHY.—No. 1,879. Three-colour photography. S. M. Procoudine-Gorsky.

COLOUR PRINTS. No. 1,533. Multicolour prints secure against photographic imitation. C. W. Lacher.

STEREOSCOPY No. 1,482. Imparting stereoscopic effect to photographic prints and positives. F. G. and J. L. McKim and H. Newbold.

CINEMATOGRAPHY.—No. 1,150. Cinematograph projection. E. Belin.

CINEMATOGRAPH-PHONOGRAPH.—Nos. 1,360 and 1,361. Apparatus for synchronous recording and reproduction of optical acoustic operations for cinematography. J. Engl, J. Masolle, and H. Vogt.

CINEMATOGRAPH-PHONOGRAPH.—No. 1,363. Arrangement for distortion, free intensification of sounds, etc., for acoustic cinematography. J. Engl, J. Masolle, and H. Vogt.

CINEMATOGRAPH-PHONOGRAPH.—Nos. 1,367 and 1,370. Production of photo-phonograms for acoustic cinematography. J. Engl, J. Masolle, and H. Vogt.

RECORDING SOUND WAVES.—No 1,372. Arrangement for recording sound waves for optional acoustical operations. J. Engl, J. Masolle, and H. Vogt.

RECORDING SOUND WAVES.—No. 1,373. Means for recording sound waves by light rays. J. Engl, J. Masolle, and H. Vogt.

PHONO-CINEMATOGRAPHY.—No. 1,398. Apparatus for transmission and reproduction of sound vibrations for phono-cinematography, etc. J. Engl, J. Masolle, and H. Vogt

CINEMATOGRAPHY.—No. 1,476. Cinematographs. J. Engl, J. Masolle, and H. Vogt.

CINEMATOGRAPHY.—No. 2,173. Cinematograph appartus. R. Goldschmied, A. Schey, and L. Zupnik.

POCKET CINEMATOGRAPH.—No. 2,173. Pocket cinematographs. R. Goldschmied, A. Schey, and L. Zupnik.

CINEMATOGRAPHY.—No. 2,062. Shutter for cinematograph projectors. W. E. Lewis.

MOTION STEREOSCOPY.—No. 1,541. Stereotopometric apparatus. J. Predhumeau

CINEMATOGRAPH-PHONOGRAPH.—No. 1,904. Process for recording and reproducing optical images and sound vibrations simultaneously. E. Reisz.

CINEMATOGRAPHY.—No. 572. Cinematograph films. H. Rieger.

CINEMATOGRAPHY.—No. 1,905. Cinematographic apparatus. R. Rigby.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

VERTICAL ENLARGING AND COPYING APPARATUS.—No. 135,484 (November 15, 1918). The apparatus consists of a vertical stand (figs. 1 and 2) with horizontal base 2, on which is placed the printing apparatus and above this the camera. The stand consists of two upright posts 1, 1. Parallel with the posts 1, a rack rod 3 with teeth 4 co-operating with a pawl 5—which may be springy—is provided on the frame 6, which is displacable on the stand in a vertical direction. The frame can thereby be held fast at any height desired above the base 2, and, by a ribbon 8, the length of which by means of a tightening apparatus 9 is adjustable, it is possible that the frame, after having been lowered, can be raised again to exactly the same height.

The frame 6 encloses a glass plate 11 and a hinged back, which forms a lid that may be in two parts, its weight keeping in position the sensitive paper which is placed on the glass plate; the lower side of the lid may be covered with white cardboard or the like in order to serve as focussing plate.

The printing and enlarging apparatus consists of a box 13 enclosing a source of light 12, with reflecting mirrors 14, and of an extension frame or insertion 16 placed on the box and on the former a camera 25 with lens 29.

In the box 13, besides the ordinary incandescent lamps, a red lamp 15 can be fitted in the current circuit in such way that by the same switch the red light can be switched off and the white lamps switched on, the red lamp being used when placing the sensitive paper.

One or more of the plates 17, 18 and 19 can be a ground-glass or an opal-glass, in order to diffuse the light and secure a uniform lighting of the negative. For contact printing, the negative is placed on a plate glass 39 in the upper part 16, and for enlargements normally in the same place. The insertion 16 contains another glass plate 20, resting

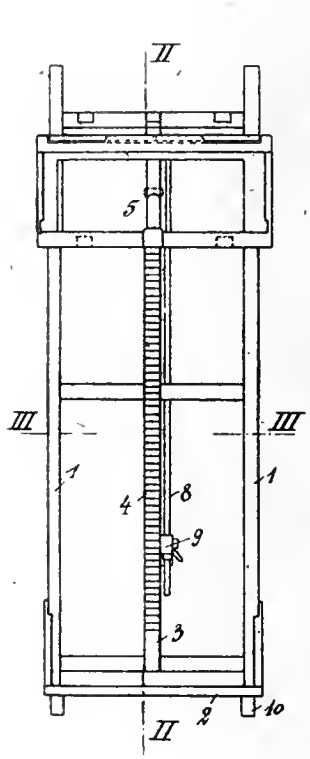


Fig. 1.

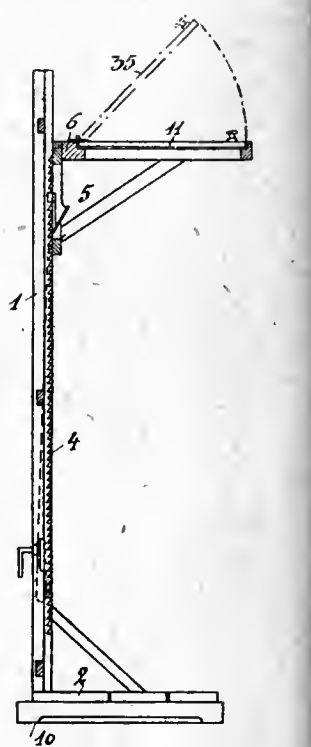

Fig. 2.

on two pairs of crank arms 22 and 23, connected by a couple of parallel slides 21, the pair 23 revolving on a common shaft 24 with finger grip and clamping-screws 40 so that the plate 20 can be raised and lowered and secured to the height desired. This glass plate, as well as the adjustment of it, serve the object, in contact printing as well as in enlarging, of enabling a vignette to be placed on the plate at a greater or smaller distance from the negative, so that the vignetting becomes softer or sharper respectively.

On the top of the insertion 16 the camera is placed, consisting of a frame 25, which is joined by a hinge at the top to a top plate 26 having a hole 27. On the plate 26 the lens board 28 is placed, so that it can be easily adjusted laterally in either direction. Its displacement is confined by a frame beading 41 along the edges of the plate 26.

In order to adjust the lens 29 vertically, the plate 26 is connected with the sides of the frame 25 by long wooden or metallic lists 30 hinged together, and by a folded cloth or bellows 31.

The adjustment is made by a screw spindle 32 with handle 33. When the spindle is turned one way or the other, the plate 26 will either be raised or lowered, and on account of the long

guiding lists 30, the movement of the plate will always be parallel with itself.

The apparatus acts as follows :—

When doing ordinary printing work the camera 25 with fittings is removed, and the negative is placed on the glass plate 39; if the picture is desired to be vignetted, the vignette is placed on the plate 20, which is adjusted to the height desired. Thereupon, while the red lamp is alight the sensitive paper is placed on the negative, a double-hinged lid 42 hinged to the insertion 16—which lid on the fig. 5 is shown turned aside—is

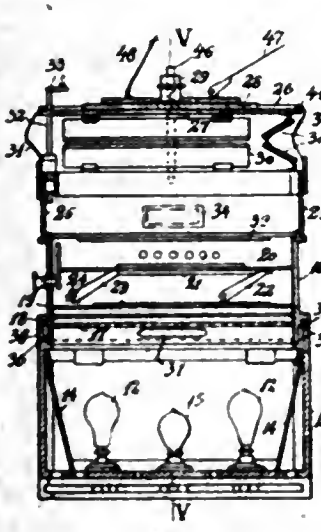

Fig. 4.

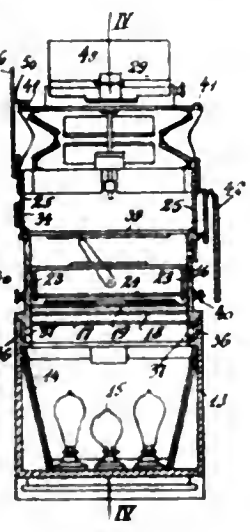

Fig. 5.

shut down and pressed against the paper during a suitable period of time, white light being switched on in the light-box 13. The paper is then removed and developed.

When negatives are enlarged or reduced, the whole apparatus is used, the printing apparatus, the lid 42 of which is turned aside, being placed on the base 2.

The negative is placed on the plate 39, the white light is turned on in the light-box 13, and the height of the frame 6 above the apparatus is determined according to the size desired of the positive. Thereupon the lens is adjusted by means of the handle 33, until the picture stands out sharply on the white cardboard in the frame 6, and the lens panel 28 is adjusted, until the picture is seen to be in its proper place in the frame.

The focussing of the picture from any desired part of the negative can also be obtained by displacing the whole apparatus laterally.

When the picture is finally focussed, the band or ribbon 8 is introduced in the tightening apparatus 9, tightened and secured. Then the pawl 5 is loosened, the frame 6 is lowered to table level, the lids 35 are opened and the sensitive paper intro-

Fig. 3.

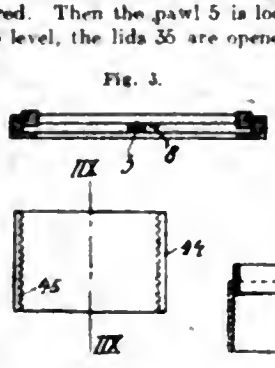

Fig. 7.

Fig. 8.

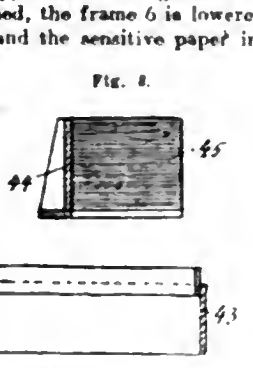

Fig. 6.

duced, the light being red. The lids 35 are shut down, and the frame 6 is raised, until it stops by the band 8 being tightened, the pawl is then in the same tooth as previously, and the frame 6 in the same height as after the focussing. The exposure is now made by turning on the white light, which is again changed to red light, the frame 6 lowered, and the paper removed and developed.

In order to be able to enlarge from large negatives it is often necessary to use longer focal lengths than usual, and a larger total extension is then required. This is obtained by inserting an insertion frame 43 of suitable height (fig. 6) between the insertion 16 and the frame 25. This extension can also be obtained by placing a frame between the plate 26 and the lens panel 28.

Reductions are made in the same manner as enlargements, with the exception that the distance from the negative to the lens must be greater than the distance from the latter to the paper, and that the position of the frame 6, after the focussing, will often be so low that it will be unnecessary to move this in order to insert the paper.

If the picture is desired to be vignetted, this can be done in two ways. Either the negative is placed on the plate 39, and the vignette below it on the plate 20, or the negative is placed on one of these two plates, and the three-sided box 44, shown in fig. 8, is placed on the same glass with the vignette inserted in one of the notches 45, so that the vignette is at a proper height above the negative. In the former case, the finished positive will show a weak tone outside the vignetted picture; in the latter case the positive will be quite white outside the vignetting.—Jens Peter Hansen, 10, Jacobys Alle, Copenhagen, V.

X-Ray Tubes.—No. 155,345. (September 10, 1919.) The invention consists of an X-ray tube capable of substantially silent operation, that is, without the hissing and crackling noises which accompanied the operation of X-ray tubes as formerly constructed.

It has been found that when the thickness of the glass wall of an X-ray tube is materially increased that the crackling noises are substantially eliminated.

It has been customary to make X-ray tubes about 0.02 inch in thickness, that is, as thin as permissible without collapse of the bulb under the influence of the external atmospheric pressure. In accordance with the invention, the walls of the entire tube, or at least the part of the tube directly surrounding the cathode and the anode head, are made of glass, having a thickness greater than about ¼ inch, and preferably a thickness of about ½ inch. Preferably the tube consists in part of lead glass, and is provided with a thin window consisting of material transparent to X rays, such as lime glass.—The British Thomson-Houston Co., Ltd. 83, Cannon Street, London, E.C.4, for the General Electric Co., Schenectady, New York, U.S.A.

The following complete specifications are open to public inspection before acceptance :—

Packing Plates.—No. 156,564. Lightproof packing for photographic plates. M. Lesjak.

Cinematography.—No. 156,575. Focussing-apparatus for cinematographs. Etablissements Continsouza (Soc. Anon.).

Projection Apparatus.—No. 156,515. Automatically focussing projection apparatus. Kodak, Ltd.

X ray Apparatus.—Nos. 156,554 and 156,678 Rontgen-ray apparatus. Reiniger, Gebbert, and Schall Akt. Ges.

Colour Cinematography.—No. 156,612. Method of producing coloured motion-pictures. A. T. Saunders.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Chat tone Series (Design).—No. 409,389. Pictorial postcards, photographs and drawings. Frederick James Saxton Chatterton, 34, Elm Park Road, Finchley, London, N.3., artist and journalist. November 3, 1920.

New Materials.

Imperial Impex X-ray Plates. Made by the Imperial Dry Plate Co., Ltd., Cricklewood, London, N.W.2.

THESE new plates mark a most important development in X-ray technique. They are the outcome of the practice which has gained ground during the last few years of employing an "intensifying" screen, usually of calcium tungstate, for shortening exposures in X-ray work. The intensifying screen, however, is not without its drawbacks, notably in the matter of definition, and when all is said and done the employment of such a screen reduces the normal exposure to, say, one-third or one-fifth. It has remained for the Imperial Company to cut at the root of this question by applying the material of the intensifying screen as an additional coating upon the emulsion film itself. By so doing it is found that, owing to the optical contact between the two surfaces, the action of the screen is very greatly enhanced so far as shortening of exposure is concerned, and at the same time the definition is comparable with that obtained on a plate employed without an intensifying screen. These are great advantages to radiographers, who, like photographers, can never have exposures too short, and will surely eagerly embrace a new method which places such great powers in this direction in their hands without corresponding disadvantages.

Thus by the introduction of the Impex plate the radiographer is placed in the position of giving 1-20th or 1-25th of the exposure which he would give to an ordinary X-ray plate used without a screen. It if is objected that the comparison between a screen-coated emulsion and one not so provided is scarcely a fair one, still, even when allowance is made for the intensifying action of a separate screen, there remains a large balance—a shortening of exposure of one-fifth to one-seventh—in favour of the new plate. On the other side of the account there is only the one additional operation in the manipulation of the plates after exposure, that is to say, the removal of the tungstate coating in warm water. The film of the Impex plate is specially hardened so that the plates can be soaked, before development, in water at about 100 deg. F. The tungstate coating is rendered soluble by this treatment, and after two or three minutes can be rinsed off under the tap. The hardened nature of the emulsion film facilitates the rapid drying of the negatives, itself a point of practical advantage in the circumstances in which the work of many radiographers is done

A practical test which we recently had the opportunity of seeing carried out was quite enough to prove to us the very remarkable properties of the new screen-coated plate. Two exposures were made in rapid succession, one of 20 seconds on an ordinary X-ray plate, which we had procured as the most rapid obtainable, and the other on the Impex plate of one second. On development the two negatives were, for practical purposes, identical, and in handling the plates we had the opportunity of observing the readiness with which the tungstate coating is removed before development.

Although the increased power of X-ray tubes and their electrical appurtenances has done a great deal to shorten exposures, the radiographer, like the immortal Oliver Twist, still asks for more, and it is doubtful whether the electricians for a long time will be able to provide him with the means of reducing exposure to such a degree as is afforded by the new plate. The demand for still greater speed is made not so much in respect to reducing exposures for thick parts of the body (already exposures have been got down to quite short periods), but in allowing of a much greater distance of the tube, and thus obtaining radiograms which are of a higher order of excellence in their rendering of bone and tissue structure. Moreover, in some of the scientific applications of X-rays exposures now run to as great a length as 24 hours: it is hardly necessary to say what an immensely wider field is opened by reducing them to one hour. Photographers will, therefore, look with envy upon these great improvements for the radiographer, and may perhaps be inclined to wonder whether a process of somewhat similar kind may not be devised to confer similar benefits, as regards sensitiveness, for ordinary photography. That, however, is another matter: it is sufficient to congratulate radiographers and the Imperial Dry Plate Company upon this very great advance in X-ray technique.

GUILLEMINOT PLATES.—The English representative, M. Jules de Gottal, 17, Cecil Mansions, Marius Road, London, S.W.17, of the old-established French firm of R. Guilleminot Boespflug and Co., kindly sends us some sample packets of the firm's dry-plates, the three chief varieties of which are the "Studio-Brom," "Radio-Eclair," and the "Radio-Brom," all plates of good rapidity, but the first-named, the most rapid of the series, and specially recommended for studio portraiture. These plates, we find, yield negatives of very good gradation and freedom from veil, and are evidently the production of a manufacturer of long experience in dry-plate emulsion making. They are issued in the English sizes from $2\frac{1}{2} \times 2\frac{1}{2}$ inches to 20 × 16, and in certain of the sizes above $3\frac{1}{2} \times 2\frac{1}{2}$ inches are obtainable in half-dozen as well as in dozen boxes. A catalogue, obtainable from M. de Gottal at the above address gives further particulars of them and of the orthochromatic variety which is also obtainable.

New Books.

Bromoil and Oil Prints. Edited by James A. Sinclair, F.R.P.S. London: James A. Sinclair and Co., Ltd. 2s. net.

THIS is the sixth edition of the compendium of papers by different writers on variations of oil pigment printing with which they have been respectively concerned. Mr. Sinclair provides the general introduction to the technique of the Bromoil process, a further chapter on which, by the late C. H. Hewitt, deals very exhaustively with the successive stages of bleaching and pigmenting. This paper was revised by Mr. Hewitt shortly before his death in 1918. It is further supplemented by Mr. F. T. Usher, one of our most expert professional exponents of Bromoil, who writes particularly on the treatment of Bromoil portraits. Mr. Fred Judge, in an article on Bromoil transfer, is explicit on technical matters, and those who have seen his enchantingly beautiful work will respect everything that he has to say. The technique of Bromoil is rounded off by a series of notes on pigmenting in colour by J. L. Tucker. The oil process is treated by M. Robert Demachy, and by Mr. Sinclair, who appends a few hints to the very clear exposition of M. Demachy. These series of chapters thus form a comprehensive miscellany of instruction in oil-pigment printing; there is, in fact, no better book to which the student of these methods can go for guidance.

THE 1921 RED BOOK.—The familiar pocket manual issued by the Affiliation of Photographic Societies has made its prompt appearance for the present year under the editorship of Mr. George Hawkings. It contains the by-laws of the Affiliation, lists of available lectures and lecturers, and a directory of affiliated societies. A feature which has been revived is a list of the places where photography is allowed only under permit, with particulars of the authorities or officers to whom application must be made, and in some cases the charges which are required. The list, of course, is a very partial one. It can only be made reasonably complete by the help of photographers public spirited enough to ferret out and send for publication particulars of these kinds of places in their own districts. It is their failure to do so which perhaps is the cause of Mr. Hawkings's lament in the preface of a lack of co-operation. If only secretaries of affiliated societies throughout the country knew this debonair youth, and his herculean work for the Affiliation, we are sure they would not hold aloof, but would contribute to a sprightlier carriage of the inevitable orchid, and an even more seraphic smile of its wearer. Mr. Wastell contributes some "Odds and Ends" to the Red Book—intricate data on exposure with diverse light-sources, postal information and notes of a practical kind. The relevance of one of these altogether escapes us. Says Mr. Wastell: "Keep hypo as a stock solution; do not dissolve it before it is required." If we are to keep hypo as a stock solution, it seems to us best to dissolve it previously, in view of the well-known drawbacks of dissolving it afterwards. In the humble desire to put the advice in o practice, the only alternative we can imagine

is to dissolve it at the very instant of use, a feat of which perhaps Mr. Wastell is capable, but in regard to which we mistrust our own dexterity.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, JANUARY 31.

Bradford Phot. Soc. "Intensification and Reduction." A. S. Dean.
Cleveland C.C. "Oil and Bromoil." G. E. H. Rawlins.
Dewsbury Photographic Society. Y.P.U. Shield Portfolio.
South London Photographic Society. "Practical Pinhole Photography for Ordinary and Stereoscopic Work." B. J. Rose.
Walthamstow and Dist. Phot. Soc. "Control." W. H. Reece.
Willesden Photographic Society. Lecturettes by the Members.

TUESDAY, FEBRUARY 1.

Royal Photographic Society. "The Cinematograph Camera—Various Models and General Description." P. King.
Bournemouth Camera Club. Print Competition.
Exeter Camera Club. "Pictorial Studies." A. W. Walburn.
Hackney Phot. Soc. Competition. "Landscape" (prints and slides).
Leeds Phot. Soc. "Photography at the Zoo." J. Manby.
Manchester Amateur Phot. Soc. "Factorial Development as Applied to Bromide Prints." Dr. B. T. J. Glover.
Portsmouth C.C. Paget Prize Colour Slides. Paget Plate Co.
Rotherham Photographic Society. "Bird Life Round Loch in Southern Scotland." R. Chislett.
Sheffield Photographic Society. "The Broad Highway—Ups and Downs of Caravanning." T. G. Askew.
Stalybridge Phot. Soc. "Bromide Enlarging." J. Taylor.
Walthamstow and Dist. Phot. Soc. Members' Lantern Evening.
Woodford Phot. Soc. "After-Treatment of Negatives." A. Dordan-Pyke.

WEDNESDAY, FEBRUARY 2.

Accrington Camera Club. "Lantern Slide Making." T. Wood.
Borough Polytechnic Phot. Soc. "How and Why I Make My Pictures." H. Felton.
Croydon Camera Club. "Pictorial Lantern-slide Making—including Double Printing." Bertram C. Wickison, F.R.P.S.
Dennistoun Amateur Photographic Association. Lecturette: Garelock Outing. J. J. Reid.
Edinburgh Photographic Society. "The Camera in Research Work." A. Eddington.
Ilford Photographic Society. "Transferrotype." W. F. Slater.
Leicester Phot. Soc. Exhibition by Messrs. Ward, Croydon, and Bailey.
Partick Camera Club. Lecturettes. C. McKenna and R. Park.
Rochdale Phot. Soc. "Bromoil Process." F. Greenwood.

THURSDAY, FEBRUARY 3.

Birmingham Photographic Society. Bromide Enlarging.
Brighouse Photographic Society. Annual meeting.
Camera Club, The. "Telephoto Lenses." L. B. Booth, M.A.
Dundee and East of Scotland Phot. Soc. "Cinematography." C. F. Partoon.
Everton and District Phot. Soc. "Reduction." G. J. Drysdale.
Gateshead and District Camera Club. "With Allenby Through Palestine with a Watch Pocket Carbine."
Hammersmith (Hampshire House) Photographic Society. "Stick and Leaf Insects." Dr. G. H. Rodman, M.D.
Hull Phot. Soc. "Psychic Photography." W. G. Mitchell.
North Middlesex Phot. Soc. Competition Prints and Slides. Members' Queries.

FRIDAY, FEBRUARY 4.

Bedford Camera Club. "Pictorial Photography in Great Cities."
Birmingham Phot. Art Club. "Autochromes." Mr. Partridge.

ROYAL PHOTOGRAPHIC SOCIETY

Meeting held Tuesday, January 25, the President, D. C. H. Rodman, in the chair.

Mrs. F. May Dickinson Berry delivered a lantern lecture on "Serbia and Jugo-Slavia before the War and After," in which she gave an interesting account of her experiences in these countries of the Balkan Peninsula. Her discourse provided many vivid sidelights upon the condition of the countries during the war, and she had some interesting things to say on the new conditions which have been created by the Treaty of Peace. On the proposition of the Chairman a very hearty vote of thanks was accorded to the lecturer.

CROYDON CAMERA CLUB.

According to the syllabus, Mr. H. P. C. Harpur was down for last week to do "Something Different," a title which did not arouse any particular curiosity, as it is not unusual for him to do something different from the rest of the world. Whether he, or it, is to be congratulated on this fact naturally depends upon the point of view.

The evening resolved itself into a gramophone recital, the hospitable demonstrator insisted that all should partake of choice refreshments supplied and brought by him. Whilst not essential to an appreciation of the concert, yet they undoubtedly helped by establishing that atmosphere of content which ever accompanies the acquirement of free drinks. As a precedent it is not to be followed, but Harpur is "Special" (ex-sergeant).

It soon became evident that he is a most enthusiastic admirer of gramophone records, and they form a large part of his life, including presumably the lives of his neighbours, who may be, or may not be, equally keen. Anyway, they have got to have it. Rumour even whispers that one-half of his waking hours is devoted to the instrument, the other half to pictorial photography, and the remainder to a strict attention to business.

Two superb instruments, richly upholstered and decorated, were operated in turn, one being made by the demonstrator. This, he said, cost him nearly £8 for materials, *plus* 500 hours' work at, say, "a bob an hour," not an extravgant estimate of the value of his spare time.

The principle of the gramophone and practical working details were clearly explained, and also some novel sound-boxes designed and made by him. One diaphragm was fashioned out of mica, on which Chinese pictures on thin paper were cemented. The Celestial tone was very apparent. Another diaphragm, constructed of cork taken from an old top-hat, also reproduced in highly correct fashion. Such excerpts as "Coronation Bells" and "Silver Trumpets" illustrated that Mr. Harpur's musical taste is not stifled by the classics; indeed, he honestly expressed a preference for brass bands.

It having transpired incidentally that he had ordered his motor to arrive at midnight, at half-time the heartiest vote of thanks was accorded him for a really enjoyable and mellow evening. Musical honours followed, Mr. Cavendish Morton's voice rising majestically above the general din. At half-past eleven, when the reporter left, Mr. Harpur, the gramophones, and a select audience were still enjoying themselves. Unfortunately the proceedings were marred by a Jazz record causing the premature death of the caretaker's cat, who, the secretary announced, had expired in agony.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square, W.C., on Friday, January 14, 1921. Present: Messrs. Marcus Adams, V. B. Basil, Alex. Corbett, C. F. Dickinson, Alfred Ellis, W. E. Gray, R. Hanos, G. Hana, H. St. George, R. N. Speaight, F. G. Wakefield, and Lang Sims, secretary (London members), and Frank Brown (Leicester), W. Illingworth (Northampton), H. Lambert (Bath), A. Swan Watson (Edinburgh), W. H. Wedlake (Forest Gate), Hallsworth Wheeler (Folkestone), T. Chidley (Chester), and Theodore Chase (Bromley). Letters of apology for non-attendance were read from Messrs. Chapman, Fry, and Read.

The minutes of the last meeting were read and confirmed.

Mr. Frank Brown reported that he and the Secretary had visited the firm of trade enlargers whose methods had been called in question at the last meeting, and that the views of the Council had been placed before the management. They had been assured by the management of the firm that their sympathies were with professional photographers, that the terms quoted by the firm for the enlargements in question were not as cheap as those quoted by some other trade houses, and that they did no great volume of business for amateurs, that the principal business was with big commercial firms, such as engineers, who employed a photographer on their own staff, and whose negatives, of course, were their own property. The firm was prepared to consider sympathetically any proposition for the advantage of professional photographers provided its competitors came into line.

The Secretary bore out Mr. Brown's account of the interview, and said that the whole crux of the question was that the firm did its main business with commercial houses.

The Chairman suggested that a small committee of those most interested in this subject shou'd be appointed to discuss the matter further and report whether a better discount could not be obtained for professional photographers as distinct from the general public.

It was agreed that the following should form this committee :—Messrs. Wakefield (convener), Gray, Haines, and St. George.

The Secretary said that in a bound volume containing numbers of the Handbook, No. 1 of the Handbook was missing. If anyone possessed that number and would hand it to him it would be of considerable value for completing the record.

The report of the Finance Committee, recommending that accounts amounting to £18 be paid, was adopted.

Mr. Speaight, as chairman of the Congress Committee, reported the provisional arrangements for the Congress. Invitations for outings had been received from three trade houses. It was recommended that one of these should be accepted. The Committee considered that members were principally concerned about receiving the latest instruction rather than a series of hospitalities; that was the reason they felt that only one trade outing would be accepted this year. There would also be an outing to the Houses of Parliament, and possibly to a firm of cinematograph-picture producers, the arrangements for which were in the hands of Mr. Marcus Adams. Lectures were promised from Mr. Luboshez, Mr. H. W. Bennett, and Madame Yvonne, possibly also an eminent photographer from abroad might lecture.

Mr. Frank Brown commended the Congress Committee on the exceedingly good work it had done.

It was proposed from the chair that the invitation from Messrs. Kodak, Limited, to visit their works during Congress week should be accepted, and this was agreed to.

The Committee considered that the installation of the new president, which had usually taken place at the close of the Friday's proceedings, had not always had the attention which was its due. It had been decided, therefore, that the Congress dinner should take place on the Friday night instead of on the Thursday night, and the formal introduction of the new president take place subsequent to the dinner, thereby ensuring it a proper place in the Congress proceedings. The arrangements for the exhibition were proceeding, and it was hoped to arrange a technical side, for which purpose Mr. Corbett had kindly consented to act on the Committee.

Mr. Speaight, as chairman of the Copyright Committee, said that he had reported at the last meeting that the representatives of the illustrated weekly newspapers, periodicals, and magazines, had been met by the Committee, and the fees for reproduction as already given in the minutes and printed on the special cards were agreed to. Since then it had been learned that one large publishing house would not fall into line. On December 30 a further meeting took place, and some pressure was brought to bear upon his Committee to alter its decision. He had replied as spokesman for the Committee that he had no authority from his Council to go back upon what had already been decided. Moreover, the journals generally were already paying on the higher scale laid down.

Mr. Illingworth and other members stated that they were securing from various periodicals the fees for reproduction as set out in the new scale.

Mr. Corbett suggested that the Secretary should be instructed to send a note to all those photographers who had signed the undertaking, telling them to continue to charge the fees as agreed.

Mr. St. George proposed, and Mr. Haines seconded, that the Copyright Committee be given full power to instruct the Secretary as to the form of communication to be sent to the signatories, and this was agreed to.

In accordance with Rule XII. nominations (in writing) for president were called for. The only nomination received was from Mr. Speaight, who nominated Mr. A. Swan Watson, of Edinburgh as president for 1921-2. Mr. Speaight said that he was sure this proposition would be unanimously agreed to.

Mr. Adams seconded, saying that Mr. Watson's presidency would form an additional link between the Edinburgh branch and the Council in London.

The nomination was agreed to unanimously and with applause.

Mr. Watson accepted the nomination, while confessing his feeling of unworthiness for the position. He would do his best, and he thanked them for the honour done him.

Mr. Frank Brown offered his congratulations to Mr. Watson, and said that he was looking forward to a very successful Congress.

The nominations for the new Council was agreed as follows :—

President A. Swan Watson.

Past President : Frank Brown.

Treasurer : Richard N. Speaight.

London.	*Country.*
Adams, Marcus.	Chaplin, W. B. (Windsor).
Basil, A. B.	Chapman, A. H. Ll. (Swansea).
Bennett, Arthur.	Chase, Gordon (Bromley).
Corbett, Alexander.	Chidley, R. (Chester).
Dickinson, C. F	Fry, S. H.
Ellis, Alfred.	Illingworth, W. (Northampton).
Gray, W. E., F.R.P.S.	Lambert, Herbert (Bath).
Haines, Reginald	Read, F. (Southport).
Hana, George.	Spink, H. C. (Brighton).
St. George, H. A.	Turner, T. C. (Hull).
Speaight, Richard N.	Wedlake, W. H. O. (Forest Gate).
Wakefield, F. G.	Wheeler, Halksworth (Folkestone).

The following new members were accepted :—Fred Hardie (Aberdeen), A. V. Eckersley (Chatham), C. M. Lee (Kuching, Sarawak).

The Secretary read a letter from Messrs. Bassano relating to the cost of electric light for studio work, and suggesting combined action to secure preferential rates.

Several members of the Council said that they got power rate.

Mr. Corbett thought that if some proposition were put forward to the Electric Lighting Committee of the Westminster City Council there would be no difficulty in getting power rates generally. He suggested that a letter be signed by the photographers of the West End of London and handed to the Secretary with a view to his approaching the chairman of the committee concerned.

It was agreed to leave the matter to be discussed between Mr. Corbett and the Secretary.

Next Council meeting, Friday, February 11.

Commercial & Legal Intelligence.

Terms of Engagement.—At the Northampton Assizes, last week, W. D. Gordon, photographer, brought an action against John Mills, photographer, St. Giles' Street, Northampton, for damages for wrongful dismissal. Plaintiff claimed 13 weeks' wages at £5 per week.

Plaintiff stated that he came on trial to Mr. Mills' studio at a salary of £5 per week. Later he entered into a twelve months' agreement to stay with Mr. Mills. Before the year expired Mr. Mills asked him to agree to stay for a further twelve months. He agreed to stay for an additional nine months. In May last year Mr. Mills gave him a week's notice, which he declined to accept, and presented himself for work the following Monday, and Mr. Mills would not employ him. Plaintiff denied that there had been any serious complaints about his work.

The defendant, John Mills, stated that in the first month plaintiff did his work indifferently. Plaintiff's work improved afterwards. When the question of a year's agreement was discussed, plaintiff refused to sign one because he wished to be able to leave at a week's notice. No agreement was signed, and a week's notice was usual in the business in the absence of an agreement.

His Lordship said that as plaintiff's claim did not exceed £65, the proper tribunal for the action to have gone to was the County Court. It was wrong to bring it to the Assizes. His Lordship accepted the evidence of defendant that no agreement was made, and he therefore found a verdict for defendant.

News and Notes.

THE HOUGHTON PROFESSIONAL BULLETIN for January contains particulars of a new style in folder mounts for miniature prints, as well as of other quite new introductions, some of which we have already noticed in these pages.

THE INSTITUTE OF PHYSICS has been incorporated for the purpose of promoting the professional status of the physicist broadly upon the lines which have been followed by the Institute of Chemistry for professional chemists. The Institute has its headquarters at 10, Essex Street, London, W.C.2.

BURY Y.M.C.A. PHOTOGRAPHIC SOCIETY.—At the second annual exhibition, to be held in the Municipal Art Gallery, Bury, from April 27 to May 25, there is one open class in which a plaque will be offered for any class of print by an amateur. Prospectus and entry form from the hon. sec., Mr. A. Benson Ray, 8, Augur Street, Bury, Lancs.

SALES MANAGEMENT.—A new monthly magazine has been issued under this title by the Louis Cassier Co., 34, Bedford Street, London, W.C.2. It is devoted to the profession or science of salesmanship, and its first number shows that it is embarking upon its programme with a full sense of the varied interests, wholesale, retail, etc., which come within the scope of its subject. "Sales Management" is issued on the 15th of each month, price 1s. 6d.

THE KAPPA WORKS, LTD., manufacturers of photographic papers, Hounslow, Middlesex, has issued a monthly calendar for the present year, and also sends us a folding set of cards arranged in alphabetical sequence for hanging on a wall and providing spaces for a register of the names of firms having telephone numbers which are in frequent request. This piece of stationery has real office utility, and no doubt any photographic dealer or wholesaler may obtain one on application to Messrs. Kappa Works, Ltd.

THE MOUNTS.—Messrs. Butcher send us a catalogue of nearly 150 pages describing, by the aid of profuse illustration, their many styles and patterns of mounts, both those for the professional portraitist and other series, chiefly slip-in, for the amateur photographer. The list likewise describes a large series of albums, and also Messrs. Butcher's novelties in the way of ready-made passepartout frames, book-post wrappers and wallets and other stationery such as a portrait establishment requires. Moreover, a book-marker makes the welcome announcement of an increase of discounts.

ATTRACTIVE LISTS in a series of six, each with a coloured cover design, are part of Messrs. Butchers' advertising programme for the coming season. Experience has convinced them that this is a form of publicity particularly advantageous to their dealer customers, by whom a supply of a catalogue may be obtained at a price which the dealer could not possibly secure independently. The lists are supplied in editions of 100, 250, or 500 at £1 15s., £4 7s. 6d., and £7 10s. respectively, inclusive of a dealer's name and address on the cover. Without this last printing they may be purchased at 5s. 6d. per dozen.

THE ENSIGN HANDBOOK of Messrs. Houghtons, which, as dealers know, is a stimulating little text book as well as a catalogue in miniature, is in course of preparation for the 1921 season, and is being offered by Messrs. Houghtons at the rate of 50s. per hundred, inclusive of the printing of a dealer's name and address on the cover. Another piece of advertising literature, specially for dealers, is a print wallet, a double envelope for carrying prints or film negatives in the pocket. These are obtainable by dealers in three sizes at prices from 32s. 6d. to 47s. 6d. per thousand, again including the insertion of a dealer's name and address.

CAMERA HOUSE JOURNAL.—In sending us the first 1921 issue of their monthly publication for dealers, Messrs. Butcher place it within a binding case which serves for the orderly assemblage of the twelve issues to appear within the year. The January number gives prominence to the British Industries Fair to be held at the White City, Shepherd's Bush, London, W., from February 21 to March 4 next, at which Messrs. Butcher will exhibit in both the photographic and toy sections. Some stocktaking bargains are itemised in this number, and there is the description of a lead lined wooden tank for the quantity development of amateurs' films.

BUTCHER 1921 CAMERAS.—The 64-page advance list, just issued by Messrs. Butcher, Camera House, Farringdon Avenue, London, E.C.4, describes the models of hand-cameras for the coming season, and shows that Messrs. Butcher have a full range, particularly of the Cameo, Klimax, and Carbine series of folding cameras. In one or two instances prices are reduced, for example, the No. 0 Watch-Pocket Carbine by 2s. 6d. and the No. 6 by 10s. The popular Pressman reflex is £1 less in price in the quarter-plate size, and dark-slides are uniformly 6d. cheaper, and film-pack adapters 2s. The list includes particulars of a roll-film tank for day-light developing of films up to 3¼ × 2¼, a simplified pattern without apron or changing box. The list is obtainable free on application to Messrs. Butcher.

THE NORTHERN PHOTOGRAPHER, in its issue of February, which appears on the eve of the opening of the Northern exhibition, gives its readers a 4-page supplement of reproductions of work there shown. Its technical contents include a paper by Dr. B. T. J. Glover on diagnosis of errors in exposure and development which, like all Dr. Glover's writings, is admirable in its precise expression. Mr. J. B. Atherton has some hints to give on high-speed photography of athletic events and similar subjects, and the æsthetic side of photography is well represented by papers on landscape photography and on the pictorial work of D. O. Hill. Our Liverpool friends, we are glad to see, take a broad view of photographic interests and are steadily making a firm place for their publication, which is published by the Liverpool Amateur Photographic Association, 9, Eberle Street, Liverpool, price 3d.

BOLT COURT LECTURES.—Lectures are given at the L.C.C. School of Photo-Engraving, 9, Bolt Court, Fleet Street, E.C., on Thursdays, from 7 to 8 p.m., by the Principal, Mr. A. J. Bull, M.Sc., who is dealing with the "Fundamental Properties of Lenses," with special reference to their application to process and colour work on January 20 and 27 and February 3, followed on February 10, 17, 24, March 3, 10, 17, by "An Introduction to Colour-work, the Composition of White Light, the Production and Scaling of Spectra, Selective Absorption, Principles of Orthochromatic Photography and Three- and Four-colour work." The lectures on colour should prove of special interest to art students, colour printers, and those interested in the photographic reproduction of colour. Mr. Bull is one of the authorities on the subjects he purposes dealing with; the numerous experiments shown will be unique and instructive. These lectures are open free to workers in the photographic, printing, and allied trades.

PHOTOGRAPHS BY WIRE.—The Christiania correspondent of "The Times" describes a demonstration, given at Sandefjord last week, of an improvement in telegraphy invented by M. Hermod Petersen, chief manager of the Radio Department of the Telegraph Service. This invention, in the opinion of experts, will revolutionise telegraphy. It is the result of four years' work, and it consists of a new system based on alternating current, instead of the continuous current system hitherto used. One of the many benefits which this invention is expected to bring is a big reduction in the number of operators needed. It is estimated that work which now requires 117 of the best operators in Norway could be done by 16. The new system eliminates errors of any kind, and reproduces with photographic accuracy, at practically unlimited distances, all sorts of handwriting, type, drawings, and photographs. One expert says that by using M. Petersen's system the "New York Times" would be able to reproduce a column from the London "Times" within 10 minutes.

PHOTOGRAPHS IN COURT.—Photographs have recently figured prominently in a legal argument which has been presenting some difficulty to the Law Lords sitting in the House of Lords. A collision occurred off the Irish coast in October, 1917, between H.M.S. "Drake," a cruiser of 14,000 tons, and the ss. "Mendip Range," a vessel of 4,9[illegible] tons gross register. Mr. Justice Roche found that there was no negligence in the navigation of either vessel, and that consequently neither was to blame for the collision. The Court of Appeal affirmed this view, and Lords Haldane, Finlay, Atkinson, Wrenbury, and Phillimore have been occupied the whole week in hearing arguments on the question whether or not there was any negligence on the part of the "Drake." Enlargements of photographic pictures which were taken at the time

by Mr. Cyril B. Potts, an apprentice on board the "Mendip Range," were produced. When some members of the crew of his vessel shouted, "Look out, she is turning, there is going to be a collision," Mr. Potts immediately ran and got his camera and took photographs of the vessel. The enlargements of these have been continually before and frequently referred to by their Lordships during the course of the week.—"Westminster Gazette."

THE PLEASURES OF MOVING.—The troubles of Messrs. Bassano in moving into their Dover Street premises were the subject of an application for an injunction in the Chancery Court last week.

Mr. Peel, for Messrs. Bassano, the plaintiffs, asked for an injunction to restrain a tenant from obstructing them in the free use of the premises, No. 38, Dover Street, where plaintiffs had leased the second, third, and fourth floors, defendant being the lessee of the ground floor.

It was stated that the upper floors were approached by a lift and by a staircase which the defendant used to the first floor, the lift being for the exclusive use of the tenants of the upper stories.

Mr. Sheldon, for defendant, argued that no one but defendant had a right to use the staircase and passage outside his rooms.

His Lordship asked what was the use of the staircase leading to plaintiff's rooms if they were not allowed to go along the passage to it? It seemed to him that the situation was Gilbertian.

Mr. Sheldon said the staircase was not the only means of entrance.

His Lordship: No, they can take off the roof and get to the place by aeroplane.

Mr. Sheldon said there was entrance to plaintiff's premises from Berkeley Street.

Mr. Peel said this entrance had been bricked up.

His Lordship observed that defendant seemed to be an obstructive person who would not let the plaintiff get to his premises.

Replying to his Lordship, Mr. Sheldon said the defendant carried on a business which he did not want to have disturbed by continual use of the passage by his rooms.

His Lordship suggested that plaintiff, if allowed to take his furniture up the staircase, should undertake not to use the staircase further pending the trial.

Mr. Peel, for plaintiff, gave this undertaking, and his Lordship also directed that plaintiff should only use the staircase for furniture which was too heavy or too large to go in the lift, and should finish the removal at the earliest possible moment. On these undertakings there would be no order.

Mr. Sheldon remarked that the staircase was smaller than the lift.

His Lordship: I have no doubt plaintiffs will undertake not to take anything through the passage that won't go through.

Correspondence.

****Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

TWO OR THREE DIMENSIONS: IDEALS IN PORTRAITURE.

To the Editors.

Gentlemen,—As a keen student of art and photography for the past forty years (exhibiting at the Royal Academy since my seventeenth year, 1879) I have been interested in your correspondence concerning ideals in portraiture, initiated by E. D. Young in his lecture upon the subject, "B.J.P." December 10, 1920.

I consider that much of real art criticism came to an end with the unfortunate lawsuit of Ruskin and Whistler, consequently the pretenders in art have gradually gained power and influence during recent years, with truly decadent results to present-day painting, which some photographers have unwisely imitated. Had I the leisure, or you the space to spare, I could give you some interesting facts concerning this retrogressive movement.

But one pen has been used with just discernment and knowledge during the past few years of chaotic art criticism, and I am pleased to read, in your issue of January 27, this pen has not degenerated to vulgar personalities, whatever differences of opinion may exist. I allude to the writings of F. C. Tilney, which have been published at various times in the "B.J.P." This gentleman is a complete stranger to me, but I value all his criticisms as accurate conclusions of present-day art and photography, which all interested people should "read, mark, learn, and inwardly digest."—Yours faithfully,

E. G. HANDEL LUCAS.

169, Gleneagle Road, Streatham, S.W.16.

January 25.

FACTORIAL DEVELOPMENT.

To the Editors.

Gentlemen,—Your readers have now fully before them Dr. Glover's reasons why he regards this method as unsuitable for out-door subjects, and also my reasons, verified by long practical use of the method, why, when an actinometer is used, the method is not only suitable, but a great help for such work. As my experience and opinion is verified and supported by the letters of Mr. Bierman and Mr. Godfrey Wilson, there is no need for me to labour the point. Here are three experienced users of the method who find that the inevitable variations in exposure in out-door negative work are not so serious as Dr. Glover claims. In a number of graphic diagrams I made years ago of times of appearance of high lights, I found that a variation of 100 per cent. between the exposures of two high lights caused a variation of their time of appearance of only 7 to 9 per cent.

Dr. Glover, however, makes a new and an incorrect surmise when he attributes my slight preference for "factorial" over "thermo-time" methods to a supposed incorrect attitude by me in the relative time for different subjects. Whether my attitude in this is right or wrong, it is a fact that I have advised and followed the same attitude in my instructions and practice for both development methods alike. I specifically stated that the point where "thermo-time" methods had occasionally failed in my hands was where either plate or developer unexpectedly proved to be different from what was anticipated. A tankful of plates either over or under developed from this reason had the same fault in all the subjects in the tank. It is significant that Mr. Bierman states that he also has been "let down" in the same way with a "thermo-time" method.

To touch upon Mr. Bierman's interesting experiences with pyro-metol developer, I point out in the Manual that all pyro and amidol developers vary in the factor required if the developer dilution is varied. And this applies to the compound developer pyro-metol. In trials years ago I found this developer rather unsatisfactory for exact work. It has such extraordinary vigour that it is always dangerously near the fogging point, and small alterations in its composition, proportion of bromide, or dilution, make quite large changes in the factor required. Almost all other developers keep to the same factor when used diluted.

I feel some difficulty in replying to the very heavy personal request which Mr. Godfrey Wilson makes to me, and if I do so, bluntly or even rudely, the facts must excuse me. Those of us who do gratuitous public work know how frequently a request is made for what is really a very heavy service under the assumption that only a small favour is asked. For example, "Oh, Mr. Watkins, I heard that at a lantern lecture you gave the other day your own lantern was used. We have a missionary meeting next week, and I feel sure that you won't mind lending us your lantern. And perhaps you won't mind coming down to work it—you do it all so nicely—we have a cup of tea going at five o'clock, etc., etc." There are invariably three characteristics of such requests: First, a slight touch of patronage; second, plenty of buttered words; third, an assumption that the favour asked is no trouble at all, but might just as well come in your day's work.

Mr. Wilson's proposal that I "send you for publication a corrected, up-to-date, and complete list of Watkins factors of developers partakes, I am afraid, of the third characteristic.

Years ago I gave some of the best years of my life to continuous and strenuous experimental work in dark-room and at the photometer. This occupied most evenings of the week, and I kept at

I was able to give (and it always was a free gift) the method with a fairly extended list of factors for most of commercial developers. I did this in hopes that users of the (and, as a fact, many hundreds took to use it) would their experience of factors, and that plate-makers and -sellers would from their trials also give factors for what sold. Neither sellers nor users have, in fact, given such I struck some years ago, and have reluctantly declined to my time in testing every new or old commercial formula which some advertiser to attach a fancy name to, ending in -ol. I have given full lists of all factors I know.

When Mr. Wilson hopes that I will send you a new and -date list of factors, he is really asking me to devote the six or twelve months to strenuous dark-room trials. My is, no. I have other work to do, and both health and sight make it undesirable.

I suggest that Mr. Wilson himself, who has used method so long, might do a little in helping his fellow workers sending to you the factors which he has found right for speci- developers, and that other factorial workers (such as Mr.) who read this should do the same. If a dozen workers this (I would gladly make the result available) quite a useful could be made to the existing information. But let all also put pressure on plate and developer makers.—Yours faithfully,

ALFRED WATKINS.

Hereford, January 22.

To the Editors.

Gentlemen,—With reference to the correspondence on factorial , there is one point which does not appear to have mentioned, and which I think has some importance, the of percentage error in the total time of development. My may be peculiar to myself, but I find it far from easy determine accurately the time of first appearance of the image, any error in timing is of course multiplied by the factor for particular developer employed. Assuming that an error of , either way is possible (I must admit to believing that I a bigger error at times), and assuming also that the fault may of anticipating the first appearance as well as of being late, will give one or two examples.

I imagine that it will be argued that it is not possible to antici- the appearance of the image, but I am afraid I do at times, and at any rate the argument is not affected. Take first a developer with a factor of 12, and a development time at 60 deg. F of 5 minutes, an error of 5 secs. means one minute in the time of development, or 20 per cent. To take the extreme case of metol with a factor of 30, and a total time of development of 10 minutes, the error becomes 25 per cent. So much for plates. When we come to bromide paper the total time of development is much less. The factor given by Dr. Glover for amidol was 12, and assuming that the paper is fully developed in two minutes the error becomes one minute, which is serious enough.

It is not necessary to push the argument further, but from this of view the developer with the smallest factor is the best.

In most cases I am of opinion, as far as I am concerned, that by inspection will not in general lead me into bigger than these.

Where factorial development is specially valuable is where it necessary to develop an unknown exposure under conditions in the temperature is unavoidably low. In such cases there always a tendency to develop for too short a period, and an error timing is a small percentage of the time of appearance.—Yours faithfully,

A. H. HALL.

January 22, 1921.

WARMING THE STUDIO.

To the Editors.

Gentlemen,—I should like to put your correspondent "Comfort" right on one or two points. He states he does not think the apparatus mentioned in a previous letter to the "B.J." could possibly be used in warming a studio, as it would be "horribly expensive" and "quite inadequate for the purpose."

The Ventiheta consumes only 5 cubic feet of gas per hour, as against the average consumption of 30 cubic feet for an ordinary gas stove, so that notwithstanding the high price of gas, the cost would only be about 4d. per day of 12 hours, and a temperature of 63 degrees is obtained. The cost, therefore, is amazingly low.

It is also quite unnecessary to have a flue to carry away the fumes, for the simple reason that for every 5 cubic feet of gas consumed, 2,000 cubic feet of pure fresh air are warmed and circulated through the room or studio. An even, warm temperature can be maintained in a studio, without any dust or damage to apparatus, furniture, or decorations. It is impossible for accidents to happen through carelessness, as no naked light is exposed.

The Ventiheta lends itself to any style of artistic decoration, as it can be supplied in any design to harmonise with the furnishing of a studio.

But why take my word for it? A visit to the Ventiheta showrooms in Argyle Street, Oxford Circus, would immediately convince "Comfort," and he would then see a perfect studio heater at last.—Yours faithfully.

FREDK. E. JONES.

Wembley, January 24.

[Our correspondent's eulogies invite comment. If 5 cubic feet of gas warm a room as well as 30 cubic feet, it can only be through improved efficiency of combustion. We greatly doubt a six-fold improvement in this respect, particularly when we are told that at the same time the gas draws in 400 times its volume of air, all of which has to be warmed. The temperature obtained will depend on the volume and temperature of this air admitted from the outside, and, therefore, it would surprise us if an installation suitable for regular use were equal to the emergency of bitter weather. —EDS. "B.J."]

CONDENSATION ON LENSES.

To the Editors.

Gentlemen,—It is so very rare to find the slightest inexactitude in your editorial notes that it seems a pity to allow even a little slip to remain uncorrected. On page 14 (January 14), you attribute the condensation of moisture on the front glasses of the lens to the fact that the warm lens is suddenly exposed to the cold atmosphere, but really the reverse is the case, as it is impossible to get a film of moisture to condense on a glass surface unless the glass is *colder* than the air.

This condensation is very liable to occur when the outfit gets thoroughly chilled on a journey, whose end is inside some building, or it may readily happen if the lens is taken out of its case on a mild day after a spell of cold weather. In the case of small pocket cameras I have found condensation occur if the warm hand is kept close to the lens for a second or two while adjusting the shutter or stop, and this may be the trouble in the case you mention, and though the effect goes off very quickly, it is possible that every negative might be fogged if the procedure was the same in every case, and the exposure made immediately.—Yours faithfully,

W. B. HISLOP.

9, Albany Street, Edinburgh.

January 19.

[We must thank our correspondent for his correction, which was occasioned by the omission of a dozen words with consequent reversal of the meaning of the second sentence in the paragraph. It should have been shown that the dewing occurs on putting a chilled camera into the warm pocket for a short time, and using it immediately after withdrawing it therefrom.—EDS. "B. J."]

KEY INDUSTRIES.

To the Editors.

Gentlemen,—Among the matters immediately to be dealt with by our legislators is the kind and measure of protection to be secured to our manufacturers from foreign competition in what are called "key industries." Although the term, in the abstract, is sufficiently explicit, it is almost inevitable that attempts will be made to include as such industries that, in the logic of words, may appear to be eligible for inclusion, but, from the particular circumstances or from the nature of the employment of the product, more beneficially could be left a free market.

Before the war the manufacture of photographic material, plates and paper in particular, was a fairly flourishing industry. The

competition was not too severe and the selling price was reasonable. Foreign competition was not entirely absent, but it was almost negligible, and, on the other hand, our exports greatly exceeded our imports. It was a healthy trade. The war had a double effect in raising prices. Acting together, shortage of the raw material and of labour and the requirements of the Air Force created almost a famine. During that time photographers were abnormally busy and could afford the enhanced price. That time is now over, and we have now to face a period of slackness, but prices are still maintained at the war scale, and are likely to remain so while the present absence of competition endures.

The manufacturers of plates and paper in this country of any account number less than 20. It is thus easy for them to form a society, a combination, or a ring to promote their own interests, and it is quite clear that they would consider any competition from abroad against their interests. They tell us there is no such society, combination, or ring, and we must necessarily believe them, but their price-lists and their terms disclose that there exists a "unanimity" which serves the same purpose; and it is quite likely that the "unanimity" on their behalf may think it comes within its province to represent their desires for protection when the matter comes before Parliament. Unfortunately, photographers have no such potent advocate of their interests. Possibly the P.P.A. may have made preparations to act, but I have seen no announcement to that effect.—I am, etc.,

C. L. SMITH.

FLUE PIPES OF ANTHRACITE STOVES.

To the Editors.

Gentlemen,—Your correspondent, "Comfort," on stoves incidentally mentions that the pipe should not be galvanised. May I recommend painting the plain iron with aluminium paint. I noticed this in use on hot-water heating pipes in Dundee some years ago, and have used it since on the anthracite stove pipes quite satisfactorily.—Yours faithfully, E. H. ATKINSON.

20, Elers Road, Ealing, London, W.13.
January 21

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. F.—We think the effect in the outline is gained by ordinary pencil work on the negative, possibly on the glass side. We should imagine that the darker outline of the profile is due solely to skilful lighting.

H. G.—There is no standard installation for portraiture by acetylene light on the market, but installations are occasionally being made to photographers' requirements. About the best firm for this purpose is Messrs. R. J. Moss and Sons, 98, Snow Hill, Birmingham.

F. H.—We have no reliable data of the number of plates or sheets of bromide paper which can be fixed with safety in a given quantity of the fixing-hardening bath, since the use of any fixing bath depends not only upon the quantity of silver in commercial plates and papers, but also on the way in which it is used and the temperature.

G. Y.—For the general questions as to construction of studio blinds, etc., we must refer you to "The Portrait Studio," which our publishers will send you price 1s. 2d. post free. This contains diagrams and fuller details than we can give here. With regard to your special requirements, as to interception of light by the school-house and aspect of studio, it is difficult to speak without knowing the height of the building. If a line drawn from the centre of the floor of the studio at an angle of 45 deg. clears the roof of the school you will have no trouble. Otherwise, you may have to use reflectors as described in the above-mentioned book. It might be desirable to have glass on both sides of the studio, as then you could work from the south-east when there was no direct sunlight upon it.

G. B. I.—Although we are sorry to say it, we are afraid that old photographs have practically no value as antiques. Apparently what you have are Daguerreotoypes. A very good specimen of this process, particularly a coloured specimen, is perhaps worth 10s. 6d. or £1 1s., if you can find a purchaser, but many of them are bought and sold among other miscellaneous goods at the photographic sales for a few pence each. We had a very fine lot of Daguerreotpyes, the property of a deceased friend, which we have sold during the last few years at good prices for his widow, and although we were able to hold for good prices, we don't suppose they have so far realised more than £3 or £4. The address of the new secretary, Mr. Lang Sims, of the Professional Photographers' Association, is 437, Brixton Road, London, S.W.9.

F. D.—We can quite imagine that the use of accumulators is a very unsatisfactory means of lighting a printing box. In using almost any light, other than electric, it is best to employ a box in which the negative is held vertically; for example, the "Hana" printing machine, formerly made by Houghtons and now obtainable fairly readily secondhand. It is one of the best printers, and can be worked with incandescent gas or acetylene. If you use a flat-bed printer, such as we expect you have at present, then you must fit up a mirror to reflect the light, and in that case you can use either incandescent gas or acetylene, although the exposures will be somewhat longer when employing, say, the extra slow gaslight papers. About the best firm for acetylene burners and generators is R. J. Moss and Sons, 98, Snow Hill, Birmingham.

G. H. C.—(1) Purchasers of figure studies are rather a large and varied class, and are rather outside our province. The "Fine Art Trade Journal," 13, Buckingham Street, Adelphi, London, W.C.2, would give you a better idea of the firms who are possible purchasers of such originals, but it may be of some service to you to go through a list of names of publishing firms who were exhibitors of goods, such as calendars, box tops and fancy articles at the British Industries Fair. (2) The price paid averages, we should say, from about 15s. to £1 1s. per subject; more perhaps for exceptional subjects. (3) The postcard people almost always buy in sets of 6 or 12; firms purchasing for other purposes are no doubt agreeable to buying odd lots. (4) In most cases firms wish to purchase entire rights of reproduction, which means, therefore, transfer of the negative, although plenty of transactions take place in which a limited right is assigned, and, therefore, the negative remains in the possession of the seller.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3170. Vol. LXVIII. FRIDAY, FEBRUARY 4, 1921. Price Fourpence.

Contents.

SUMMARY.

Mr. Thomas Bolas, in a contributed article, gives practical directions for the making of a backing (with ox-gall basis) which is always ready for use, and is found to be highly effective. (P. 63.)

Mr. W. Ermen has carried out tests showing the relative degrees of exhaustion experienced by various developers as regards the colour of prints. (P. 64.)

The utility of employing a stereoscopic camera for the purpose of duplicating exposures, preferably on different plates, when undertaking particularly difficult subjects, is discussed in a series of notes by P. R. S. (P. 65.)

In a leading article we refer to some of the text books dealing with the first and second decades of photography, which, with many others to be referred to later, are listed in the comprehensive catalogue of scientific works recently issued by Messrs Sotheran. (P. 62.)

A correspondent questions the necessity of variation in the lamps contained in a printing box, as suggested last week by Mr. Drinkwater, when other means, such as the use of matt transparent screens or local shading devices, allow of the result being much more simply and economically obtained. (P. 71.)

The secretary of the Professional Photographers' Association announces that Mr. Marcus Adams is acting as honorary secretary of the exhibition of professional photographic work, to be held in connection with the forthcoming P.P.A. Congress at the Photographic Fair. Technical work, as well as portraiture, will be admitted to the exhibition. (P. 71.)

At the Royal Photographic Society, on Tuesday evening last, Mr. P. King read a paper on cinematograph cameras, and makers and designers of these instruments demonstrated their movements. (P. 68.)

At the annual dinner of the Affiliation, Mr. G. C. Weston briefly sketched a scheme of decentralisation which, it seems to us, has certain distinct merits. (P. 61.)

A single counterbalanced electric lamp has its special utility in studio portraiture. (P. 61.)

Details of construction of an anastigmat objective, consisting of three single glasses, are given in a recent patent specification. (P. 66.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In a contributed article Mr. R. M. Fanstone gives a number of hints on the spotting and other retouching of Autochrome and Paget colour transparencies. (P. 5.)

A notice of some of the colour transparencies shown at the Northern Exhibition will be found on page 6.

Practical hints on the development of Autochromes, a whirler for drying these transparencies and a method of using several light-filters during one exposure of an Autochrome plate are contained in paragraphs on page 8.

Some further notes on the old "Hillotype" colour process and its relation to methods of direct heliochromy are contained in letters. (P. 7)

EX CATHEDRA.

Electric Lamps. In the majority of half-watt installations the lamps are in fixed positions, or they are grouped in a stand or cabinet so that they can only be moved as a whole. This rather limits the variety of effects which can be obtained, and a single lamp which can be moved about independently is a very useful adjunct. The ordinary sliding standard will answer in most cases, but in small studios is rather liable to be in the way. In such circumstances the balanced fitting which was introduced with the Van der Weyde light may be adopted with advantage. This consists of an arm about eight feet long, pivoted at the centre with a universal joint so that it can be rotated or elevated and depressed. At one end the lamp is fixed; at the other is a sliding balance weight, a touch of the hand sufficing to place the light in any position. With such a fitting, carrying a 3,000 c.p. lamp and suitable reflectors, all the effects of lighting which made Van der Weyde famous could be reproduced. In the original form the light was fitted on a 42-inch reflector, but with the half-watt lamp the standard metal reflector would be more suitable.

* * *

The Affiliation. At the annual dinner of the Affiliation of Photographic Societies with the Royal Photographic Society, the chairman of the executive committee, Mr. G. C. Weston, referred to one movement within the Affiliation which he thought would be necessary in the near future to give full effect to the activities of that body. He had in contemplation a scheme embodying a certain measure of decentralisation, according to which groups of societies should be formed among those constituting the Affiliation upon a geographical basis. Affiliated societies are, of course, scattered throughout the United Kingdom, and inter-communication which goes on between those which geographically are related to each other does so, or at any rate is supposed to do so, through the medium of the executive committee at Russell Square. If we understand Mr. Weston rightly, it is his idea that machinery should be provided for bringing societies within a given area more closely into relation with each other by arranging for them to carry out exchanges of lectures and lecturers and generally, for example, by means of an area committee, to localise and intensify the services which the Affiliation can render. Undoubtedly, there is a great deal to be said for a scheme of this kind, for the usefulness of it is witnessed by the independent unions or federations which have come into existence since the establishment of the R.P.S. Affiliation in 1892, and owe their strength to the exercise of such functions as Mr. Weston now proposes for his groups. We have only to look, on one side at the list of lecturers in the Red Book and on the other upon the help which many societies derive from Affiliation lectures and lecturers, to see that there is the occasion for giving definite shape to a scheme of this kind.

Returning Money. We have been asked whether a customer can legally claim the return of any money paid at the time of sitting, if he or she is not satisfied with the proofs submitted and does not find it convenient to give another sitting. This is a delicate point, and if the matter were carried into court the decision would depend upon the impression which the photograph produced upon the judge, who, though skilled in law, might be altogether lacking in artistic perception. We should, in these circumstances, recommend the photographer to cut his loss at the earliest possible moment, and to return the money with as good a grace as possible, and certainly without any unpleasant comments, rather with an apology and a request for future orders. This leaves the sitter with the impression that the photographer is at least an honest and obliging person, and if she fares no better elsewhere she is likely to return to him with friendly feelings. This end is cheaply purchased at the cost of three or four plates and proofs. In the great department stores there is an understanding that "the customer is always right," and breakages and damages are allowed for, when it could be clearly proved that the fault did not lie with the firm.

THE EARLIER LITERATURE OF PHOTOGRAPHY.

I.

The issue of Messrs. Sotheran's "Bibliotheca Chemico-Mathematica," to which we refer on another page, provides an appropriate occasion on which to draw to photographers' notice the many pieces of literature which have long been out of print, yet possess a great interest for any but those who are content with a very superficial knowledge of photography as a whole. We are ready to confess that we fear the number of persons having this broader interest is small. Among the hundreds and thousands of people who "do photography," there are comparatively few interested in photography in the se se of the knowledge of photographic processes which has accumulated and is recorded in the literature since the appearance of the first work, that by Daguerre, in the year 1839. Nevertheless, we should like to do something to encourage a wider reading of the subject; and we cannot do that better than by calling attention to the opportunity of acquiring some of these bygone books which is afforded by Messrs. Sotheran's painstaking and accurate work in cataloguing those they have for sale. Moreover, the expenditure need not be great; with the exception of some of the scarcest of these works, for example, that by Daguerre, the average price is only a few shillings. Fortunately for the photographic student the bibliophile has not included photographic works among those which he covets, with a corresponding elevation of their price, as he has those in other branches of literature and science.

We notice that Messrs. Sotheran's list includes two of the classical pamphlets relating to the origin of photography, namely, Fox Talbot's "Some Account of the Art of Photogenic Drawing," the paper read before the Royal Society early in 1839, in which Talbot broadly outlined his discovery but did not give any precise details. The other is Sir John Herschel's paper "On the Chemical Action of the Rays of the Solar Spectrum on Preparations of Silver," a communication of 1840 which recorded Herschel's further observations, particularly the bleaching action of mercuric chloride, now familiar as the most commonly used intensifier, and the ferro-prussiate or blue-print process in almost precisely its present form. Among the works of the first decade of photography, 1840-1850, notable ones are "Nouvelles Instructions sur l'Usage du Daguerréotype," by Charles Louis Chevalier (1841), in which is described an improved racking camera for the process and directions given for the use of bromine in the sensitising of the plates, and "Derniers Perfectionnements apportés au Daguerréotype," by Gaudin and Lerebours, with a chapter by Fizeau on his process of gold toning which gave to the delicate images a permanence, without which the process could hardly have lasted as long as it did. Turning to the English literature of the period, a scarce book is Robert Hunt's "Popular Treatise on the Art of Photography," the first Glasgow edition of 1841. Hunt was a prolific experimenter in and writer on photography, and his "Researches on Light," issued in 1844, and in a second edition in 1854, contains a mass of observations relating to the action of light on inorganic and organic substances, which make it one of the most valuable books even for the present-day experimenter. A curiosity among this early literature is "Das Kaleidotyp, oder Katadioptrisch-Chemische Maschine," by Friedrich August Wilhelm Netto, a pamphlet of 1843 describing a combination of the kaleidoscope and Daguerreotype for the mechanical production of industrial designs. A far-seeing experimenter, Herr Netto, with an eye on the main chance.

The discovery of the wet-collodion process by Scott Archer in 1851, and the consequent speedy disappearance of Daguerreotype, gave a great impetus to publications dealing with what was then regarded as the "new photography." An important early work of this second decade is Gustave le Gray's "Photographie: Traité nouveau," first published apparently in 1852. As students of photography of the fifties know, the collodion positive attracted perhaps even more notice than the system of making negatives on collodion plates, since it provided a cheap and easily-worked substitute for the Daguerreotype plate, which previously had found enormous favour with the public. We are uncertain as to the origin of the collodion positive, but Messrs. Sotheran ascribe it to a work "Photographie Nouvelle: Procédé pour obtenir des Epreuvres Positives Directes sur Glace" of Adolphe Martin, published in 1852. But about this time text books began to be more plentiful; for example, Delamotte's "Practice of Photography" of 1853, a manual for students and amateurs, and the first popular handbook on photography. In 1855 Thomas Sutton wrote his "Calotype Process," and in the following year his "Dictionary of Photography," the first work to be compiled in an A.B.C. form. Nor should we omit from this catalogue of books of the early collodion period the "Manual of Photographic Chemistry," by T. F. Hardwich, which ran through edition after edition, and for many years continued to be one of the most widely-read text-books. Later editions were edited by George Dawson and Traill Taylor. We come in 1862 to the early "Traité Populaire de Photographie sur Collodion," by the Belgian experimenter, Desiré van Monckhoven, which in French and English passed through several editions. The development (and also the vulgarisation) of the collodion positive has its counterpart in later works on ferrotype, such as those of E. M. Estabrooke, "The Ferrotype" of 1872 and "The Ferrotyper's Friend" of 1880, both of Cincinnati.

Although two other works are of very much later date, we may refer to them here, since they deal particularly with the early history of photography. The first of these is an English translation, "A History and Handbook of Photography" of Tissandier's "Les Merveilles de la Photographie." The second English edition of this work is really the most valuable version, since it contains an

appendix by Fox Talbot (completed by his son, C. H. Talbot) on the development of his work in photographic and photo-mechanical processes. Tissandier himself is not by any means a thorough-going historian; his "history" is a lively recital into which unverified tradition and anecdote enter in considerable measure. The other work, however, in which the student of photographic history will find much to interest him is, on the other hand, the outcome of great scholarship and exact research—we refer to "Wedgwood: the First Photographer," by the late Mr. R. B. Litchfield. But our notes on these early books have already outrun their space; we must defer reference to those dealing with the later period of photography until a subsequent issue.

AN "ALWAYS-READY" PLATE BACKING.

As "always-ready" anti-halation backing in a full sense of the term; the mixture being always ready to hand without becoming dry in the pot, or absorbing an undue proportion of water from the atmosphere, and moreover the plate is ready for exposure immediately; no drying being required, while finally the developer is in no way damaged, so that no wiping-off is required previous to development; nevertheless, if desired, a full view can be had at any stage of the development, as a touch with a soft brush clears any part of the backing instantly during development, if an undermentioned precaution is taken.

This combination of advantages is realised by taking advantage of the hygrometric and other properties of ox-gall, the ox-gall being used in the form of the purified ox-gall of the pharmacist; additional and incidental advantages are ease and certainty of application, notwithstanding finger marks or like greasy patches on the back of the plate, and the complete elimination of halation under the most trying conditions: the optical union of plate and backing being perfect owing to nearness in refractive index, and the peculiar soap-like viscosity of the mixture.

The purified ox-gall of the British Pharmacopœia (*Fel bovinum purificatum*) can be obtained as a yellowish-green, viscous mass from any pharmaceutical chemist, or it may be prepared by following the instructions on p. 147 of the 1914 edition of the British Pharmacopœia. Evaporate half a litre of fresh ox-bile to one-fourth of its volume; shake with twice its volume of 90 per cent. alcohol. Set aside to clear, filter and evaporate on water bath to the consistency of an extract.

The backing mixture consists of one weight-unit of the purified ox-gall, four weight-units of gum arabic mucilage, and one weight-unit of vegetable black water-colour, as sold in a collapsible tube, these being well mixed after the containing pot has been warmed in the water bath for a few minutes. A rather stiff, flat brush, a string or wire across the mouth of the pot for striking off any excess from the brush, and a larger pot to cover the whole closely, complete the equipment for backing, but a cover plate for the backing is desirable. This at best is a plate of matted black glass, with corner-pieces of thickish microscopic cover glass, cemented on with Canada balsam, to prevent contact and inconvenient adhesion, but an old negative with four corner-pieces of thick paper gummed on is a substitute. Obviously only one sensitive plate can be used in an ordinary double back under these circumstances, but two sensitive plates may be used in the double slide if a thin sheet of black celluloid is laid on the adhesive backing of each plate and the two celluloid backs are placed together in the slide.

A note on the thin black, flat celluloid, a remarkably useful material in the photographic work-place. Thin celluloid is stained, first green with an alcoholic solution of acid green, then red with an alcoholic solution of magenta, in such ratio as to produce the best of all blacks, a mixed black. After washing in water to remove any soluble remainder of either colour, the celluloid is ironed flat between sheets of stout paper.

A very small quantity of the backing is required if the layer is uniform, say, 4 grains for a quarter-plate, and it is seldom or never desirable to apply the backing quite up to the edges of the plate.

Ordinarily the protecting or covering celluloid should be peeled off before the plate is put into the developing solution, and it is more convenient to drop the plate through the developing solution than to put the plate in the dish first and then pour the developer on; as in this latter case the backing is so immediately and uniformly softened that a touch with the finger or a soft brush will clear a place at once, should back views or through viewing be desirable.

There is, however, one case in which it is desirable to leave the protecting celluloid on, or to use an adherent protecting plate at the back, that is to say without the corner-pieces for giving distance. This is when the so-called "Aktinal" system of desensitising and subsequent daylight development is adopted (see article "Aktinal," p. 13 of 1912 edition, Cassell's "Cyclopædia of Photography.") In this case the protecting plate or celluloid is of use in preventing the soiling of the desensitising fluid (4 per cent. potassium iodide solution), which if thus protected may be used for several or many plates in succession.

The developer which I prefer to use, and one which I regard as a near approach to a universal developer, whether for plates or paper, is a rather strong hydroquinone developer with sodium sulphite and sodium carbonate:—

Hydroquinone	45 grs.
Cryst. sodium sulphite	2 ozs.
Cryst. sodium carbonate	2 ozs.
Water	5½ ozs.

(Total volume about 8 fluid ozs.)

This keeps well, has a Watkins factor of about 5, and I have never found it necessary to add bromide excepting under conditions like those of the "Aktinal" process or the Playertype process, when the film contains two grades of material, each developable, but in different degrees.

Even those professional photographers whose activities may be wholly confined to the studio, would do well to consider the service occasionally rendered by backing. The full lights and shades of a clear white dress cannot be rendered on an unbacked plate, and to copy an engineer's blue print is almost hopeless unless on a backed plate which should also be orthochromatic.

THOMAS BOLAS.

AMIDOPHENOL DEVELOPERS.—A recent patent specification, No. 154,198 (not yet accepted), of Hauff & Co. relates to photographic developers of the amidophenol or amidocresol class made with the addition of sulphite and soda or potash, and wherein alkaline salts of the carbo- or sulpho-acids of the ortho- or para-amidophenols or the orthoparadiamidophenols are present. In order to restore to such solutions containing carboxyl and sulpho-acids their original developing powers a further quantity of free caustic alkali is added. A developer instanced contained muriated paramidosalicylic acid (100 gms.), sulphite free from water (500 gms.), normal lye of 5-fold strength (210 c.cs.), and water (5,790 c.cs.). For use, this stock solution is diluted with an equal or double quantity of water, and a further quantity of ordinary soda lye added, according to the exposure and requirements.

EXHAUSTION TESTS ON DEVELOPERS.

A short while ago I was accorded the privilege of describing in the columns of this journal the method of preparing concentrated developer solutions by the help of caustic soda. The time of appearance of the image on bromide paper was taken as a measure of the activity of these solutions, and was always determined in a freshly-made solution, which solution was never used more than once. But this is not the way developers are most commonly used for the production of prints. On the other hand, print after print is put through the same solution, until this becomes too slow in its action, or begins to give bad coloured blacks, partly owing to the accumulation of soluble bromides and developer oxidation products in the liquor, and partly owing to actual destruction of the active developing agent, by aerial and chemical oxidation. Not enough is known as yet about the chemistry of development for us to be able to assign its proper value to these various factors separately, but their combined effect can be measured with some degree of accuracy by noting the time of appearance for a number of prints developed one after the other in a not too concentrated solution, if care is taken to keep the exposure and the temperature constant.

For this purpose I have used two types of developer formula: "Rodinals," containing 5 parts of developer per 100 of liquor, and solutions containing:—

Developer	2 parts.
Soda sulphite (anhydrous) ...	12 ,,
Soda carbonate (anhydrous) ...	12 ,,
Water to...	1,000 ,,

The carbonate solutions were used undiluted, the "rodinals" diluted with 24 volumes of water, so as to bring them to the same strength as the former. Quarter-plate Kodak Platino-Matte bromide paper was given such an exposure behind a Sanger-Shepherd test plate as was sufficient to produce faint image of the twelfth square. The temperature of the dark room was 65 deg., and 100 c.c.s. of developer solution was poured on to the dry paper, and allowed to act until no further image appeared to be formed.

The print was then taken out of the developer, allowed to drip into the dish for ten seconds, rinsed and fixed. The developer was then poured out of the dish into a beaker ready for the next print. One print after another was developed in the same (constantly diminishing) lot of liquor, until either the time of appearance became inconveniently long, or the last square failed to appear at all.

Six developers in carbonate solution were first compared:—

Para-amido-phenol Metol Dimethyl-para-amido-phenol	Fig. 1.
Para-amido-ortho-cresol (Monomet) Methyl-amido-ortho-cresol Para-amido-meta-cresol	Fig. 2.

On examining these curves we see that para-amido-phenol shows the longest time of appearance of any of the six bodies in the fresh solution (4.75 seconds), whilst methyl-amido-ortho-cresol and para-amido-meta-cresol have the shortest time, only 2 seconds, closely followed by dimethyl-amido-phenol (2.2 seconds), with metol and monomet between 3 and 4 seconds.

After 12 prints have been passed through the solution, methyl-amido-ortho-cresol still has a time of appearance of only 3 seconds, whilst metol, monomet, and dimethyl have risen to 6 seconds, the meta-cresol compound to 8 seconds, and amido-phenol 10.

After about 30 prints the developers are all practically exhausted: metol reaches 54 prints with a time of appearance of 22 seconds, monomet 25 seconds, whilst amido-phenol has fallen to 33 seconds, and methyl-amido-cresol, which began so well, only gives 29 prints with a time of appearance of 34 seconds.

Quinol and chlorquinol (chlorhydroquinone) were also examined in the same way, but at a concentration of 4 grammes per 1,000 c.c.s, instead of 2 grammes, so that their curves (Fig. 3) for the same concentration as the other developers should begin with times of appearance 22 seconds and 60 seconds respectively. It will be seen that these two developers are not only very slow at the start, but begin to fall off

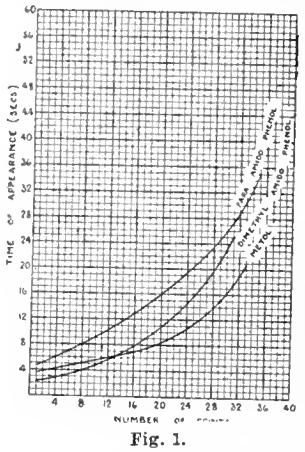

Fig. 1.

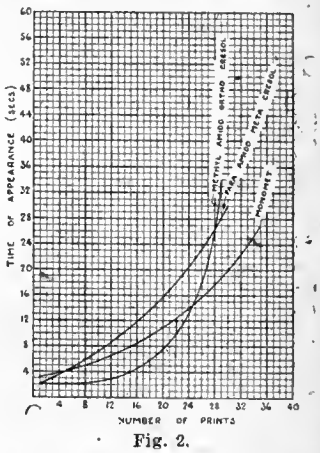

Fig. 2.

in speed right away at a very great rate, chlorquinol being much less easily exhausted than quinol.

On the same figure are shown the curves of decay given by metol and monomet in combination with quinol:—

Quinol	10 gms.
Monomet or metol...	5 ,,
Potass metabisulphite	45 ,,
Caustic soda	*q.s.*
Water to	300 c.c.s.

The first time of appearance for both these mixtures is again very short; but both fall off with great rapidity, the curves soon becoming almost straight lines, and the total number of prints obtainable is much smaller than in the case of carbonate solutions of the amido-phenols or cresols alone. Monomet can only give 17 prints, metol 24.

Fig. 4 shows the curves given by monomet and chlorquinol

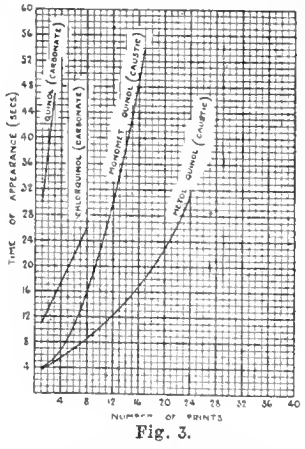

Fig. 3.

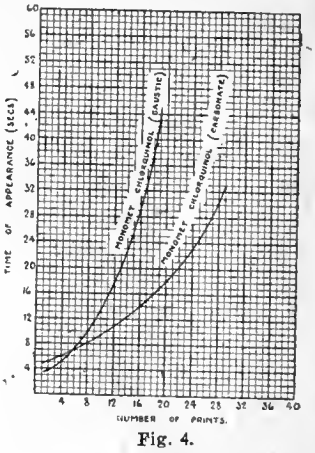

Fig. 4.

in caustic and carbonate solutions respectively. As one might expect from the behaviour of quinol and chlorquinol alone (Fig. 3), these mixtures fall off much less rapidly than those containing quinol and monomet, the carbonate solution being more stable and giving more prints than the "rodinal." I have mentioned above that all the prints were developed apparently to a standstill. Where the time of appearance was short the development factor was about 10, but as the

time of appearance lengthened the factor gradually fell, till it had reached a value of not more than 4.

The quality of the prints so produced cannot, unfortunately, be shown in an illustration, but, as a general rule, all the prints produced by one developer were very similar in strength and degree of contrast, with the exception of the last one or two of a series, where the high-lights began to fall off badly and the shadows looked weak and muddy.

There was very little difference noticeable between any of the single developer, carbonate, prints: all were inclined to be soft. Those containing quinol showed a stronger contrast, and altogether appeared to contain much more deposit. The heavy shadows were dense blacks and not merely dark greys. Chlorquinol alone was very similar to quinol in this respect, but was quite free from staining in the whites, whereas all the quinol prints were somewhat tinted.

Presumably a similar relationship between the different developers described above will hold for plates. I hope to be able to carry out this investigation at some future time.

W. Ermen.

DUPLICATED EXPOSURES FOR DIFFICULT SUBJECTS.

Occasionally one is called upon to make a negative of an extremely difficult subject, a subject which would perhaps cause the most experienced of us to pause and wonder whether a self-screen, ordinary, or a filtered colour-sensitive plate would give the best result, or, may be, whether an exposure of one hour or two hours is wanted, or, again, whether *f*/6, or, say, *f*/16, would give the better result. If the exposure of two plates is possible, and one is not limited as to time, the problem may be easier to solve, though the exposure of two plates becomes a very serious matter when the times of exposure are very long, as they generally are when working in dimly- or peculiarly-lighted interiors, the light coming through old stained-glass windows being at times very deceiving. Expense is also a consideration, especially when large plates are employed.

A professional worker of my acquaintance was called recently in great haste to a certain Royal residence where he was requested to make a negative of a room then vacant for about two hours, and although the exposure necessary was only about twenty minutes, he only exposed one plate, even though he had ample time to expose more. It was, however, quite certain that neither he nor anyone else would ever again have an opportunity to photograph the room as it had been left by men famous in the world's history. Blessed is the man who has such confidence in his abilities: unfortunately, I have no such confidence in mine, although a photographer of thirty years' experience in many parts of the world.

During recent years I have adopted a plan of dealing with difficult and uncertain subjects, a plan I can recommend, it not calling for much outlay, possibly none at all in many cases. I wish now that I had adopted it twenty years ago, when difficult subjects were for me the order of the day. I refer more particularly to the tasks of photographing the traditional scene of the Nativity and the Manger at Bethlehem, and the various sites in the Church of the Holy Sepulchre at Jerusalem. In each of these places, however, I managed to secure six exposures by flashlight before the priest custodians became alarmed, because of the fire and smoke, and bundled me and my tools most unceremoniously out of the buildings.

My present-day plan of dealing with extremely difficult subjects is more awkward to describe than to work. My apparatus consists of a double quarter-plate stereoscopic camera fitted with a pair of Dallmeyer's old C.D.V. portrait lenses, and I have also a pair of Petzval lantern objectives fitted with home-made stops of cardboard, as well as several other pairs of lenses of various foci. My idea, however, as I shall explain, is not to make stereoscopic pictures. I make this statement now in case my readers cease scanning these remarks in the belief that I am trying to revive stereoscopic photography.

I use the old Dallmeyer portrait lenses more often than any of the others, because they are invaluable for difficult subjects of most kinds. These lenses (made in 1868) are similar to the well-known Petzval instruments, the difference being in the shaping and arrangement of the back combination. These old Dallmeyer lenses are, I believe, fairly common to-day, and may often be picked up very cheaply. Such is my outfit, in which there is nothing new: my method of working, however, is, I believe, out of the common.

My aim, as I have said, is not to make a stereoscopic pair of prints, but rather to secure at one exposure two different results—two quarter-plate negatives of different qualities—and to make use of the better one, perhaps destroying the other. It is for this reason that a double quarter-plate camera is employed, one made by Chadwick, who was a strong advocate of the double-quarter size for stereoscopic work. The camera allows of two quarter-plates being used side by side, a thing the orthodox stereo camera does not permit of. The two quarter-plates I use side by side are rarely of the same brand, but of two different makes. Thus in cases of uncertainty when the use of, say, an ordinary plate or a self-screen cannot be decided upon one of each is used. One may also use ordinary plates of high and low H. and D. numbers to form a pair, a screened isochromatic and a panchromatic, and many other combinations, the worker selecting the two most likely to give the best results, rather than results which differ widely.

These differences in the sensitive plates, used on the same subject, are combined with the play one has with stops: changes may be rung to any extent. Sometimes particularly when stops are manipulated to make the exposures required about the same, there is little to choose between the two negatives, but in most cases one is better than the other, and from the better one the necessary enlargements are made.

Further differences in the quality of a pair of negatives on plates of different makes may be secured, if necessary, by developing with different developers. Most of my most difficult interior subjects are taken on an ordinary plate with a self-screen plate as its bedmate in the dark slide. Pyro-soda is commonly used as the developer for the self-screen plate, and M Q or Azol for the ordinary plate. I find the plate combination named the best for architectural "bits" in churches and old buildings, far better as a rule, than a pair of ordinary plates of different speed numbers, or a pair of like plates used with stops differing but little in their F values. In practice there is not a noticeable difference in plates of the same variety having different H. and D. numbers, unless, of course, the latter differ widely—a fact which speaks volumes for the extraordinary latitude to be found in modern dry plates. It is when using two plates of the same brand, if not of the same speed—that the use of a different developer for each comes in handy to give one a choice of negatives.

The choice of plate to make up a pair likely to give two good results depends largely upon the subject to be pictured, for although two perfect negatives are not to be scorned one only is necessary, as the worker is not making a pair of prints to illustrate an advertisement of a panchromatic plate; he is simply having two chances of taking something where

perhaps only one is possible when working in the usual way. And although my best results have been obtained on one or other of a pair made up of a self-screen and an ordinary, some subjects call for a self-screen and an ortho plate with a yellow filter, while others may suggest a self-screen and an unscreened panchromatic, and so on.

The old portrait lenses, as well as the Petzval lantern objectives, are really excellent lenses for difficult architectural "bits." The large apertures permit of easy focussing, and fairly large stops may be used when only the centre of the negative is wanted for enlargement. My practice is to get my subject within a 3-in. square marked upon each half of the focussing screen, and let the remainder take care of itself.

This plan of working calls for a double quarter-plate camera, or one of the orthodox type with plates cut to fit, and, as so many workers have stereoscopic cameras lying idle, it may be that my hints may be of service to those who desire to find a use for them, and who, like myself, are sometimes puzzled to know what plate, exposure, or method of development will give the best result.

P. R. S.

FORTHCOMING EXHIBITIONS.

January 22 to February 5.—Northern Photographic Exhibition, Walker Art Gallery, Liverpool. Particulars from the Hon. Secretary, Liverpool Amateur Photographic Association, 9, Eberle Street, Liverpool.

February 14 and 19.—Leicester and Leicestershire Photographic Society. Latest date for entries, February 5. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

February 19 to March 5.—Edinburgh Photographic Society. Latest date for entries February 10. Particulars from the Hon Secretary, G. Massie, 10, Hart Street, Edinburgh.

February 19 to March 12.—Scottish Salon, Dundee. Particulars from the Hon. Secretary, James Slater, Rosemount, Camphill Road, Broughty Ferry.

March 16 to 19.—Hackney Photographic Society. Latest date for entries, March 1. Particulars from the Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 13 to 23.—Portsmouth Camera Club. Latest date for entries March 31. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Latest date for entries, March 17. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Latest date for entries, April 16. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs.

THE AFFILIATION DINNER.—The annual dinner of the Affiliation of Photographic Societies was held on Saturday last, January 29, under the chairmanship of Mr. G. C. Weston. A large company, including many ladies, spent an enjoyable evening, interspersed with items from a lengthy musical programme arranged by Mr. George Hawkings. The speeches were few. Mr. T. H. B. Scott proposed the toast of the Royal Photographic Society, to which Dr. G. H. Rodman replied. Mr. J. Vacy Lyle, in an exceedingly witty speech, proposed the toast of the Affiliation, in responding to which the chairman, Mr. Weston, referred to the things which the Affiliation had accomplished, and briefly outlined some of the directions in which he thought it was necessary for it to advance. Mr. W. L. F. Wastell proposed the toast of the Visitors and the Artists, to which Mr. Hawkings replied.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, January 17 to 22:—

COLOUR PHOTOGRAPHY.—No. 2,720. Colour photography. L. Keller-Dorian.

PRINTING-FRAME.—No. 2,530. Self-masking printing-frame for photography. C. J. G. Goodman.

REPRODUCTION METHOD.—No. 2,822. Photographic method for pictorial reproduction of a solid. L. Lumière.

STEREOSCOPY.—No. 2,339. Method of producing stereoscopic phenomena. T. E. R. Phillips.

CINEMATOGRAPHY.—No. 2,835. Cinematographic apparatus. T. Baron, A. E. Bettles, R. Neil, and F. R. Parnell.

CINEMATOGRAPHY.—No. 2,795. Cinematographic apparatus. S. H. Crocker.

CINEMATOGRAPHY.—No. 2,813. Cinematograph lantern shutters. H. F. Edney.

STEREOSCOPIC PROJECTION.—No. 2,584. Producing or projecting pictures showing a stereoscopic effect. B. F. J. Day and J. F. Duke.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

TRIPLET ANASTIGMAT LENSES.—No. 155,640 (September 22, 1919). The invention relates to an improved triplet anastigmat lens comprising three single lens components, of at least two different dispersions, each of which components has a refractive index for the D-line greater than 1.61, where the middle dispersive lens is placed symmetrically or approximately symmetrically (to within 10 per cent.), between the outer, double convex lenses, the combination having an aperture-ratio of at least 1 : 3.

It is well known that the symmetrical form offers considerable advantages in the correction of distortion, coma and chromatic difference of magnification. In fact these aberrations are automatically corrected in a symmetrical lens working at unit magnification. A photographic objective, however, is usually used at magnifications varying from zero to unity, so that the best result is obtained by correcting the lens at some magnification less than unity. This leads to some slight departure from the strictly symmetrical form. In the lenses to which the present invention relates, the separations and lens thicknesses are practically equal (within 10 per cent.), but the lens curves in front of the mid point of the system, *i.e.*, nearer the object, are shallower than those behind, but the difference in the powers of corresponding surfaces is no more than 25 per cent. of the power of the complete system. A better correction is thus obtained by slight departure from strict symmetry, without losing the advantages of symmetry.

Previously lenses of this type have been made of three glasses, in which the positive lenses are of crown glass, of high n_D and

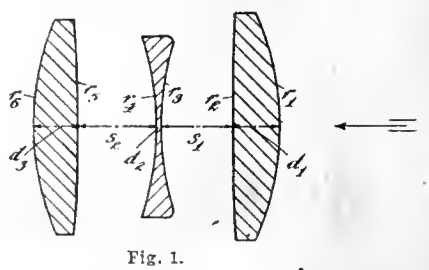

Fig. 1.

low dispersion, combined with flint glass of lower n_D and higher dispersion as described in Patent No. 15,107 of 1895, in which

the aperture ratio did not exceed *f*/6.5; also, in the case of a lens with aperture *f*/4 as described in Patent No. 22,607 of 1893, in which the positive lens consists of crown glass of low refractive index, combined with flint glass of higher negative index; also, in the case of a similar lens with aperture *f*/6, as described in Patent No. 4,714 of 1911. Also in the lens described in Patent No. 2,619 of 1911, where the mid lens is not placed symmetrically with regard to the outer lens, and these outer lenses are not double convex but plano-convex and meniscus respectively. Furthermore, in the first two cases it was stipulated that the coma ("diaphragm corrections") should be removed in all these lenses simultaneously.

Calculation has shown that this last condition is not necessary to the correct performance of a lens as a whole, and moreover, that to obtain a large aperture-ratio it is necessary to use glasses of high refractive index for both positive and negative lenses.

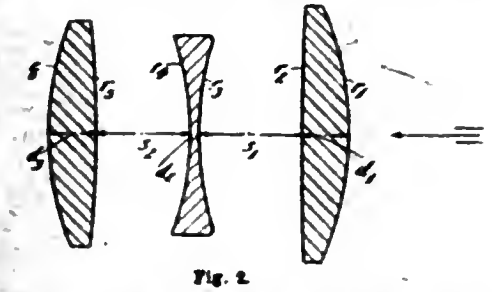

Fig. 2.

In a lens thus formed, the flatness of field is obtained by the use of highly refractive glass for the crown, and freedom from spherical aberration by the use of highly refractive flint.

Two numerical examples of lenses made according to the improved construction of the present invention, will now be described with reference respectively to fig. 1 and fig. 2 of the accompanying drawings; the letters PM. and C. referring to the catalogues of Parra-Mantois and Chance respectively.

EXAMPLE I. (Figure 1).

Equivalent focal length 1 unit; the radii, etc., being expressed in the same units. Aperture ratio F/3. Flat field of view 45 deg.

Radii	Thicknesses	Diameters	n_D	Nu-value	
$(r_1) + .4013$ / $(r_2) - 5.370$	(d_1) .06	.34	1.613	58. 5	PM.6540
Separation (s_1) .10			1.		
$(r_3) - .4702$ / $(r_4) + .4001$	(d_2) .01	.3	1.621	36. 2	C. 361
Separation (s_2) .1076			1.		
$(r_5) + 2.345$ / $(r_6) - .3794$	(d_3) .06	.3	1.613	58. 5	PM.6540

EXAMPLE II (Figure 2).

Equivalent focal length 1 unit. Flat field of view 35 deg. Aperture ratio F/3.

Radii	Thicknesses	Diameters	n_D	Nu-value	
$(r_1) + .4156$ / $(r_2) - 4.64$	(d_1) .06	.34	1.613	58. 5	PM.6540
Separation (s_1) .13			1.		
$(r_3) - .4266$ / $(r_4) + .3603$	(d_2) .01	.3	1.621	36. 2.	C. 361
Separation (s_2) .121			1.		
$(r_5) + 1.8138$ / $(r_6) - .3546$	(d_3) .06	.3	1.613	58. 5	PM.6540

—Taylor, Taylor and Hobson, Ltd., and Horace William Lee, B.A., Stoughton Street Works, Leicester.

The following complete specifications are open to public inspection before acceptance:—

AERIAL MAPPING.—No. 157,236. Process and apparatus for the production of maps from overlapping, oblique photographic views. Ipag. Internationale Aerogeodatische Ges.

COLOUR CINEMATOGRAPHY.—No. 157,196. Cinematograph projection of coloured and other images. E. Belin.

New Books.

Photographic Technique. By L. J. Hibbert. London: Sir Isaac Pitman and Sons. 2s. 6d. net.

MR. HIBBERT, in his preface, says the aim of this little book is "to deal thoroughly with the elementary stages of photographic technique." The editor of the series (of which the manual is one) declares that each book treats of fundamental principles "in a practical manner." Technique and fundamental principles! There you have a declared conflict of aims; for technique, even in the sense unrelated to fine art which it has come to have, may be (and usually is) empirical from beginning to end without reference to fundamental principles. We suspect that this little text-book has come to grief through these discrepant aims. Its obvious defect is unsteadiness of key, little flutterings between principles and technique. Flutter No. 1 is a spasmodic excursion into the wave-theory of light: a pretty subject, of course, but it soon has to be left in the lurch, because in such a manual you can't teach either the purely optical or the photo-chemical facts of photography in terms of that theory. Mr. Hibbert has a try at it, by way of "explaining" the formation of an image by a lens, but in the next paragraph (p. 23) he has exchanged the physical conception for a little flutter in geometrical optics, which adds nothing to the understanding of conjugate foci, and moreover contains a confusing literal error.

The fact is, he is trying to do a great deal too much in 115 small pages. He would have done better not to have gone so far back in the effort to relate fundamental principles to photographic operations. In the parts of the work where he is telling the student to do this or that, and is not over-anxious to assign a reason, he is altogether excellent—clear, concise, and technically correct without exception. We notice only one or two passages which invite a dissenting comment, *e.g.*, it is rather misleading to refer to bichromate as the "sensitive salt" in the carbon process; and the recommendation to use so strong a solution as 1 part of .880 ammonia with 3 parts of water as the darkening bath in mercuric intensification is surely a slip of the pen.

Bibliotheca Chemico-Mathematica. London: Henry Sotheran and Co. 1921. 2 Vols. £3 3s. net.

To catalogue over 17,000 books in any way whatever is a task of some magnitude, calling for a vast amount of clerical work and a large measure of skill in arrangement if the compilation is to be of service. What, then, must have been the total of the long and patient labour which has preceded the publication of this great catalogue of scientific and technological works? Though it is a commercial catalogue—the books are for sale—it represents the expenditure of precise scholarship on a scale without parallel in the sale of any other goods. Messrs. Sotheran have undertaken this great task as bookmen rather than book dealers, and have spared no pains to make the list a bibliographical work of great value. That such has been their aim is shown by the cataloguing of innumerable works which are offered at a shilling or two. On a mere sales basis it could not conceivably pay to compile or print the numerous entries for these latter. It can only have been done with the object of providing students and collectors with the knowledge gained at first hand by the sellers. The bibliographer is worthy of his hire; we hope that their courage in issuing these two large volumes will not go unrewarded.

Since the chemical, physical, and mathematical sciences provide the greater part of the subjects of the works here catalogued, an adequate review would be out of place in these pages. Even the photographic literature which is here represented we cannot discuss at the length it deserves in a notice of the "Bibliotheca," but we refer to it in an article on another page. Here, however, we must point some features of the catalogue. The arrangement is according to authors, and a great deal is done in giving the full names of authors identifying them with their chief discoveries or inventions, providing the key to pseudonyms, and introducing in the appropriate place, in the Appendix form adopted in the British Museum catalogue, particulars of books *on* as well as *by* a given scientific writer. The inclusion of the date of publication of

every work catalogued and the notes distinguishing different editions are other valuable features, but chiefly are to be mentioned the profuse annotations, some quotations from recognised authorities, others by the compiler of the catalogue. All this bibliographical commentary, as Mr. Sotheran very cordially acknowledges in the preface, is by Heinrich Zeitlinger, a German whose opinion of the modern Junker-dominated Germany may be gathered by such footnotes as "every book by a professor at Louvain will serve as a memorial of the irruption of the savages in 1914."

Exigencies of production have made it impracticable to make the catalogue one single alphabetical list. It comprises several such lists, viz., pp. 1 to 284 of vol. I., pp. 285 to 788 of vols I. and II., and a classified list, pp. 789 to 868 of vol. II. In looking up an author the student must therefore note that there are two main alphabetical lists. A key to the subjects treated in this vast collection is provided by a subject index which itself occupies nearly 100 pages, and is a highly analytical guide to the literature of the fields and sub-divisions of the mathematical, physical, and chemical sciences and their applications. Finally, the catalogue is enriched by 127 plate illustrations, reproductions of title pages of the classical books of science, drawings, diagrams, specimen texts and portraits. These add a relish, if such were needed, to the list. They serve to give prominence to the classical pieces of literature, but they are not necessary to the plan of this exceedingly valuable catalogue, which, without them, would still be a work both invaluable for reference and of inexhaustible interest to anyone dipping here and there in its pages.

News and Notes.

THE HACKNEY EXHIBITION.—Any exhibits sent to this Exhibition can be forwarded to Portsmouth and Hammersmith or other Exhibitions carriage paid.

TELECTRO PHOTOGRAPHY.—The current issue of the "World's Work," that for January, contains a long illustrated article describing the technics of the processes worked out by Korn, Belin, and others for the electrical transmission of photographs.

THE estate of Sir William Abney, K.C.B., D.C.L., D.Sc., J.P., of Measham Hall, Leicester, adviser to the Board of Education (Science Department) and an accepted authority on photography and the subject of colour vision, who died on December 2, has been proved at the gross value of £27,534, with net personalty £12,869.

DRAWING AND SURVEYING APPARATUS.—Messrs. Holmes Brothers (London), Ltd., Walthamstow, E.17, have just issued a catalogue of the drawing boards, T-squares, plane tables, and other appliances of the draughtsman and surveyor which are manufactured by them, and include also drawer cabinets for the storage of plans, etc., and printing frames for the making of photo-copies.

DEATH OF CAPTAIN G. R. ILLINGWORTH.—The many friends in the photographic industry of Mr. Thomas Illingworth will extend their sympathies to him and to Mrs. Illingworth in the death of their second son, Captain Guy Russell Illingworth, I.A., 91st Punjabis, who met his death in a motor accident at Poona, India, on January 21. Captain Illingworth was only 22 years of age.

Commercial & Legal Intelligence.

LEGAL NOTICES. Notice is given of the dissolution, by mutual consent, of the partnership between Ernest Foster and Joseph Thomas, carrying on business as sports and photographic dealers, etc., at 159, High Street, Poole, Dorset, under the style of Thomas & Foster. All debts due to and owing by the late firm will be received and paid by Joseph Thomas, who will continue the business.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, FEBRUARY 7.

Bradford Phot. Soc. "Natural History Photography." G. A. Booth.
Catford, Forest Hill and Sydenham Phot. Soc. Print and Lantern Slide Competition.
Cleveland Camera Club. Whist Drive.
Dewsbury Phot. Soc. "Amateur Photographer" Prize Slides.
South London Photographic Society. "Faking." M. O. Dell.
Walthamstow and District Phot. Soc. "Lantern Slide Making." E. Willcocks.
Willesden Photographic Society. "The Present-day Importance and Power of Photography." A. Dordan-Pyke.

TUESDAY, FEBRUARY 8.

Royal Photographic Society. "A New Method for the Measurement of Photographic Filter Factors." Raymond Davis. "A Description of a Monochromatic Illuminator Designed for a Special Purpose." F. C. Toy, M.Sc., A.Inst.P. "A New X-ray Plate, Reducing Exposures to One Twenty-Fifth; Its Special Applications to Radio-Metallurgy." Dr. Leonard A. Levy, M.A., F.I.C., and T. Thorne Baker.
Bournemouth C.C. "Blood Parasites." Dr. Coles.
Doncaster Camera Club. "Memories." C. F. Walker.
Exeter Camera Club. "A Loon in London." W. L. Wastell.
Hackney Phot. Soc. "Time and Tank Development." A. Dordan-Pyke.
Leeds Phot. Soc. "On the Track of the Raiders." R. Mackay.
Portsmouth Camera Club. Miss Kate Smith's Portfolio.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, February 1. Following routine business, the president vacated the chair in favour of Mr. E. W. Mellor.

Mr. P. King delivered a lecture on commercial models of cinematograph camera, illustrated by a large number of lantern slides, and also by exhibits of the actual apparatus. Like the photographer's stand camera, although in a different way, the cinematograph camera has its "movements," which from the nature of things are altogether different from those which in ordinary photography are contrived for the more effective use of a lens which may be of any focal length from, say, 5 to 20 inches. But in the cinematograph camera the optical system is of negligible importance, that is to say, in respect to the design of the camera. When it is remembered that a 2-inch lens on a cinematograph picture is

working at the quite narrow angle of 30 deg., whilst the cinematographer will rarely use a lens of greater focal length than 5 or 6 inches, it will be understood that it is not the purpose of the camera to help out, so to speak, the performance of the lens. On the other hand, the cinematographer requires to do a host of other things with his camera—view the picture whilst exposure is taking place, vignette the picture down to a vanishing point and back again whilst the film is running, combine accurately two exposures on each of the tiny film sections, run the film at speeds much less or greater than the normal 16 pictures per second. The list might still be added to and then not exhaust the "movements" which particularly for trick effect work is required of the camera. Mr King dealt very explicitly with the commercial patterns of camera on the market, explaining the different ways in which these various functions were performed, and showing the different degrees of complication of the respective mechanisms. He was fortunate in having persuaded to come to the meeting the makers or designers of a number of the instruments. Following his lecture, Mr. Van Neck explained and demonstrated the "Aeroscope" air-driven cinematograph hand-camera; Mr. Vinten showed the camera of his design; Mr. Arthur S. Newman delivered quite a little lecture on the almost human movements of the Newman-Sinclair camera; a representative of Messrs. Moy showed this firm's camera; Mr. Colin Williamson very clearly explained the technics of the cameras of his design; and lastly, Mr. King himself, on the suggestion of Mr. Colin Bennett, showed and briefly explained the De Brie camera.

Votes of thanks to the lecturer and to these demonstrators brought the proceedings to a close.

CROYDON CAMERA CLUB.

The annual general meeting was held last week, when, as anticipated, everything was found to be in a thoroughly satisfactory state. Mr. Ackroyd, the treasurer, announced a good profit for the year, apparently derived from ever-threatened deficits, for the rent alone of the club rooms about equals the subscriptions. The hon. secretary still sticks it, plaintively remonstrating at appropriate and disregarded intervals. He read a shorter report than usual, couched in congratulatory vein. Once again, right through the year the club has run a continuous round of lectures and demonstrations. Mr. Inskeep preserves the best traditions in the refreshment department, and the "office boy" continues his rest cure with unabated zeal.

As regards President John (surnamed "Keane"), under a rule limiting office to two years, resignation, desired by him, would have been secured automatically. This rule was made many years ago to meet the special case of a fixture in the chair. No further need for it exists, and it, and not the president, received the order of the boot. Right well has he served for four years with a gap midway, and has most materially helped to carry on during trying times. As a slight recognition of this, a few friends conferred with one another, and last Wednesday the conspiracy bore fruit in the shape of a presentation to him of a handsome clock.

Prior to the imposition of an entrance fee (the subscription remains unchanged) new members were rapidly roped in to the "house full" point. Subsequently the rush materially abated, though whether this be cause and effect or merely coincidence cannot be stated. As illustrating the peculiar lure of Croydon, one new member, whose initials are appropriately "O. D.," travels from Hendon; the latest hails from Battersea; and, to cap all, an application for membership was received from a sporting resident in Sarawak—a Britisher, not one of the wild men of Borneo, as might be expected.

At the end of the proceedings Mr. Salt sternly indicted the president and secretary, the charge being that, on divers occasions, they had discharged out of their own monies certain obligations which in fairness ought to have been met by the club. He regarded this misappropriation of liabilities as one of the worst cases which had ever been brought to his notice, and asked that the accused be severely dealt with. Thanks largely to a well-intentioned defence put up on their behalf by Mr. Harpur, both were unanimously found guilty, and the Council was directed to take all steps to prevent a repetition of the offence.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.

A general meeting was held at the Albion Hotel, Manchester, on January 26. Among those present were Messrs. F. Read, J. W. Stott, W. H. Baylis, Duke Dawson, F. Cummins, F. Kenworthy, R. H. Greswell, J. S. Browne, H. Taylor, W. G. Frisby, E. J. Carr, W. T. Carter, J. W. Berry, B. Goodman, A. Goodchild, and A. Walmsley.

Mr. Fred Read, president, took the chair. In the absence of the secretary, Mr. Hulse, Mr. J. S. Browne acted *pro tem.*

The question of Sunday closing was raised by a letter from Mr. Parkinson, of Warrington, and was discussed by Messrs. Goodman, J. W. Berry, R. H. Greswell, and F. Kenworthy, among others. Mr. Walmsley, in response to a request for his views, said that he had done a great deal more business since he adopted Sunday closing. On the proposition of Mr. Kenworthy, seconded by Mr. Carr, it was decided that all members should be asked to vote on the question.

The hon. solicitor, Mr. J. G. Mahaffy, then gave a short address on the Rent Restrictions Act as applied to business premises. He outlined the chief points of the amended Act which shortly comes into force, and pointed out that it provides a much greater degree of protection for tenants of business premises, since it gives greater security of tenure to the person who has established a profitable business and so enhances the letting value of premises occupied by him by creating a valuable goodwill. Moreover, the owner or agent was compelled to offer suitable alternative accommodation, a somewhat difficult matter in view of the nature of a photographer's business. Mr. Mahaffy advised any of those among his audience who might receive a blue form from the landlord to take no notice of it; if necessity compelled them, they might consult their solicitor, who, he thought, would be able to set their minds at ease. A hearty vote of thanks was accorded to Mr. Mahaffy for his address.

Mr. J. S. Browne then introduced a discussion on prices and price cutting. He quoted from letters and price lists received from manufacturers, one of whom stated that there was no immediate prospect of any reduction in prices owing to the continued high level of the cost of raw materials and wages, whereas another notified the introduction of postcards at a reduction of 10s. per thousand and with offer of a larger discount.

Mr. R. H. Greswell spoke at some length on the subject in special reference to photographers keeping up prices to a working level consistent with the prevailing figures for labour and materials. The general conclusion was one of deprecation of the British manufacturers in maintaining the enhanced prices which it was found necessary to impose during a period of great shortage under war conditions. Manufacturers were no doubt aware that at the present time the market was receiving foreign materials which were much cheaper, and the consumer could not be blamed if he bought in the cheapest market to the disadvantage of the British manufacturer.

A vote of thanks was accorded to Mr. J. S. Browne for his services in organising the meeting, which then adjourned to a larger hall and spent the rest of the evening in the enjoyment of a musical programme arranged by Mr. W. H. Baylis. A vote of thanks to the artists contributing the entertainment was proposed by Mr. F. Kenworthy and seconded by Mr. W. T. Carter.

DENNISTOUN AMATEUR PHOTOGRAPHIC ASSOCIATION.—Last week, members were treated to a most instructive and interesting "Elementary Talk on Lenses," by Mr. G. F. Burrell. The speaker gave a brief *resumé* of the principles of optics and the formation of images. Proceeding to the aberrations of lenses, he explained spherical and chromatic aberrations, astigmatism, curvature of the field and distortion, and indicated the methods used in their correction. The lecture was illustrated by means of apparatus devised by the speaker—a spectroscope and a lens-testing bench—on which the various aberrations were pointed out. Mr. Burrell promised to give a further talk on the subject this (Friday) evening, February 4, and members are asked to bring any lenses which may not be giving satisfaction to the meeting room, 27, Hillfoot Street, and have them tested.

RAILWAY PHOTOGRAPHERS.

To the Editors.

Gentlemen,—Mr. G. W. Atkins in his letter (published in the "B. J." dated January 21) throws an interesting side light on early railway-photographic history, his story of seeing Mr. Bridge at work at the North London Railway's Works in 1869-1870 proving Mr. Bridge to be one of the earliest railway operators.

Those of us, however, who are particularly interested in photographic history have always looked upon the elder Thomas Scotton as being the first of the really official workers, and talks with old photographic and railway hands at Derby and elsewhere have convinced me of the fact that Mr. Scotton was working—solely and officially—for the Midland Railway Company in July, 1876. There were, of course, photographers at work for railway companies long before this date, but they were called in from their own businesses to do the work—as Mr. Bridge probably was, and Mr. Scotton, too, before his appointment. Derby photographers before 1876 appear to have shared the Midland's work, for many of the early Midland engines (before 1876) were photographed by Mr. W. W. Winter of Derby.

The archives at Derby must contain an immense quantity of interesting photographic-railway material, the collection of which was begun before the days of Mr. Scotton. There is, for example, a set of 15 × 12 wet-plate negatives of plans showing the proposed St Pancras Hotel and station, and although not dated it is said they were made in 1855-1856 by a Mr. Warwick, who at that time was employed in the company's telegraphic department.

The Midland did not bring its railway to London until 1866, although it was talked of and preparations made many years before, the palatial terminus not being built until 1873-1876.—Yours faithfully,

L. Tennant Woods.

KEY INDUSTRIES.

To the Editors.

Gentlemen,—Your correspondent C. L. Smith seems to hit the nail on the head. We, as professional photographers, at the present time are very much imposed on by manufacturers of all sensitised surfaces.

It is a fact that an extremely strong arrangement exists between the makers of all these articles. It is certainly not a ring, as rings and trusts are not allowed by law for the purpose of controlling prices, but it is patent, owing to the fact that practically every maker of sensitised material in this country has identical price lists, identical terms, and wholesale and professional lists common to the whole of them, that the profession is up against a price maintenance arrangement.

During the war, when there was practically no competition, one did not trouble very much about this, and any costs were put on to the finished article, but matters are very quickly becoming different. We are up against lower selling prices, yet we get no consideration whatever from the controllers of British sensitised materials. A certain amount of foreign material is now coming into the country at prices in some cases a little more than half the war prices, which are still being maintained by British sensitisers. The cost of silver has come down, the cost of raw materials has come down, and many of our makers are actually getting baseboard, and even glass, from the Continent at very much lower prices than they had to pay for the home-made article during the war, and it is evident that they do not intend to give us any advantage until they are compelled.

It is rather surprising that they should wait until inquiry commences as to prices before they see fit to reduce their figures. "Much wants more" is very true in their case, for, looking round, it is easy to see that many of the firms with extensions, and their principals in evident affluence, are doing well. Nobody wishes them otherwise, but at the same time they ought to give a little consideration to their humbler brethren in the trade.

If the Professional Photographers' Association get busy at once they will have no difficulty in proving when the time comes that it is not to the good of the photographic profession of this country that they shall any longer be without the advantages of reasonable competition by foreign and allied makers.—Yours truly,

Alfred Jones.

26, Grange Terrace, Halifax, January 28.

MATT GROUND PLATES WANTED.

To the Editors.

Gentlemen,—Now that we are settling down to business again after the war, and getting most of the materials we are in need of—if we can afford to pay for them—may I, through your columns, ask the plate-makers to give matt ground plates another and a fair trial? We have now amongst us hundreds—possibly thousands—of new workers who have never heard of matt ground plates, and it is possible that such plates would become very popular.

The first matt ground (or surface) plates I met with were those made—experimentally, I believe—by Mr. E. J. Wall, a generation ago, and some years later the Leto Company placed an "Edwards" matt ground plate on the market, but these, I understand, were not a commercial success. Only last week I came across an opened box of these old plates (batch No. 5,890), and they are as perfect to-day as on the day of manufacture.

The advantage of having dry plates, with a ground glass-like emulsion, was appreciated by those who used them, and the advantage will be obvious to present-day workers who may have had no experience with them. I do not suppose for one moment that matt plates would replace the clear variety, but there should be a good sale for them among portrait and landscape workers. I do not suggest that all plate-makers should issue them, but they might agree that one firm should again give them a trial, the other firms following if the plates were found to be a success. Failing this arrangement, could such plates be made to order?—Yours faithfully,

H. Green.

WARMING THE STUDIO.

To the Editors.

Gentlemen,—I am sorry to have to disagree with my old friend, Mr. F. E. Jones, but when he expects us to accept his statement that 5 cubic feet of gas per hour, however consumed, will warm a studio, he is asking too much. It may do so just now when the temperature outside is higher than last July, but it is quite impossible to keep a fairly large studio really warm in frosty weather with two *large* gas radiators. The Ventiheta might keep an ordinary room, with small windows, from being chilly, but I am quite sure it would not make a studio comfortably warm. And a studio must be warm in winter. We cannot get a pleasing portrait of a sitter who is shivering with cold.

After some thirty years of constant studio work I ought to know something about it. And no one but a photographer knows the difficulties of making the studio comfortable at all times of the year. In the summer it must be kept cool, if possible. This cannot always be done; but in the winter it is possible to keep it warm, if adequate arrangements are made. Five feet of gas per hour is not adequate, especially with 2,000 feet of air pouring in from outside, when it may be freezing hard. I remember a stove which worked on that principle, but in cold weather it failed to keep even a small office warm unless we stuffed a duster into the air inlet.

I have tried many ways of warming studios—coke stoves, open fire places, plus gas radiators, hot-water pipes, and lastly an anthracite stove, the last has proved the best; but the ideal would

an open fire-place, plus hot-water pipes. A stove or a fire-place gives an air of cosiness to a stodio, which is a valuable asset in making a sitter feel at ease.

I work in a studio measuring 33 ft. x 21 ft., and, of course, there is a large area of glass, and the room stands free of the rest of the building, except at one end, so that the two sides and one end are outside walls, at the top of a building exposed to every wind that blows. Does Mr. Jones ask me to believe that 5 feet of gas per hour is going to keep that room warm?

During the sharp spell last December I had to use a gas radiator for an hour or so every morning to get the studio really warm, when the stove alone was sufficient. The moral of which is—always have some means in reserve of raising the temperature. I am quite sure that the most convenient, most efficient, and cheapest means of heating a studio, in the absence of hot-water pipes, is an anthracite stove.

Mr. Atkinson, I think, has misunderstood what I wrote about galvanised pipes, or perhaps I expressed myself badly. I did not mean that the flue-pipe should not be galvanised, but that the ordinary galvanised pipe of thin sheet iron, which is soon corroded into holes, should not be used, but one of cast iron. Aluminium paint can be used for such a pipe quite successfully, but it makes the ugly pipe rather conspicuous; ordinary blacklead would be better, especially if the stove can be fixed in a shady part of the room.—Yours, etc.,

COMFORT.

AN IMPROVED BOX PRINTER.

To the Editors.

Gentlemen,—It was with very much surprise that I read in Mr. Drinkwater's article on the box printer the words, "It seems as if there were no powers of control over exposure other than shortening or lengthening the period of contact. There are no means of locally intensifying or reducing the power of the light, to overcome inequalities in opacity in various parts of the negative, and this is a control that is at times very urgently needed." I am still wondering what kind of printing box Mr. Drinkwater has been using, because in all those I have seen the arrangements for control are excellent. The first printing box I used I made myself, and arranged so that any shading of the various parts of the negative could be done with ease.

A few inches above the lamps a sheet of glass is fixed, upon which sheets of waxed paper can be laid to diffuse the light, and these can be made of any shape necessary to reduce the light where required; if a part of the negative needs more exposure, the paper can be cut away to allow more light to reach the negative. But the means of shading is only used when broad spaces have to be controlled. For instance, in one 12 x 10 negative of a long, narrow picture six sheets of waxed paper were used at one end and only one at the other. The first sheet was laid upon the glass full size, the next was cut an inch or so shorter, and so on. For controlling the light for smaller parts a second sheet of glass is fixed about an inch below the piece of plate supporting the negative; on this tissue paper can be laid, cut to the necessary shape, and, if necessary, parts can be shaded by working on the paper with black lead or chalk. If still more exact shading is required, a piece of common ground glass can be laid immediately under the negative and worked on with black lead. If it is desired to give more light to some part, a little olive or other oil can be painted on the ground glass to make it more transparent. Surely here is control enough without moving the lamp at all.

I find that I get the best results by keeping, where possible, to an exposure of five seconds, with ordinary bromide paper. If the negative is thin more waxed paper is laid on the glass shelf, and if it is dense the paper is taken out; and if the negative is one that is likely to be used again a note of the number of sheets of paper used, and also the developer, can be made on the envelope.

Working with a regular time of exposure often prevents waste of paper through wrong exposure, because it is quite easy to forget the time, if it changes with each negative; for example, if a large number of prints have been receiving seven seconds and the next negative, after trial, is found to need only four seconds, an absent-minded printer (and there are such people about) may forget all about the four seconds after he has printed one or two and give the next seven seconds, quite unconsciously, and does not find it out until the prints are developed. I have done it more than once myself. Then it is easier to time five or ten seconds more accurately, owing to the divisions being more clearly marked on the clock face. It is not difficult with average negatives to control the light by adding or removing tissue paper so that five seconds may be the correct exposure.

Mr. Drinkwater's arrangement of having 17 lamp holders inside the box would need a huge box to take them, and the board on which they are fixed has to be moved up and down to secure control of lighting. This seems to me like putting the fire in the middle of the kitchen and making the joint revolve round it to cook it equally, instead of having a fixed fire and turning the meat round with a jack.

It appears to me to be better to arrange the lamp holders to give the most even lighting possible, and then control it locally when required.

To enable the 100 c.p. lamp to be lowered to 23.5 in. from the negative means having a box at least 30 in. deep. Altogether it would be a very big and clumsy thing for the printing room of the average provincial photographer. And I do not think it would be as effectual in securing control of lighting, nor so convenient to use, as a very much smaller box, such as those already on the market.—Yours, etc.,

BIFOCAL.

HUMOURS OF PHOTOGRAPHY.

To the Editors,

Gentlemen,—During the course of a discussion recently, a friend suggested that photographers, as a rule, lacked a sense of humour, and claimed as a proof of this statement the fact that there are no humorous photographic short stories or anecdotes to be found. Whilst disagreeing with the first statement I was bound to accept the "so-called proof" as true, at the moment, but merely because no effort had ever been made to record humorous photographic incidents. Are there any good stories of photographic humour to be found, amateur or professional? Surely some of your readers could supply at least one. It would afford me the greatest possible pleasure to compile a collection of such storyettes, etc., and to present a copy of the completed work to each person contributing to it: also, provided fifty or more are forthcoming, to offer a prize of £2 2s. for the best and most humorous contribution. I feel sure that such a collection is possible, and if you will grant space in the "B.J." for this letter, an interesting, entertaining and desirable book might be obtained.—Yours most faithfully,

WILLIAM A. RICHARDSON.

81, Rayleigh Road, Wolverhampton, Staffs.,
January 29.

THE P.P.A. EXHIBITION.

To the Editors.

Gentlemen,—May I, through the hospitality of your columns, inform members of our profession that the P.P.A. annual Congress is fixed to take place at the Royal Horticultural Hall, Westminster, in April next, and that my Council are arranging a very attractive programme?

The particular object of this letter is to call attention to one of its most important features, viz., the picture exhibition, which, for the first time, will include specimens of "technical" with that of "portraiture."

The Exhibition Committee are engaged drawing up the rules, which will shortly be in the hands of the members. My desire is to call attention to the importance of this opportunity to exhibit, from a "publicity" point of view, and to urge all those whose ambition it is to be "hung" to begin looking up suitable pictures, so as to be ready when "sending in" time arrives.

If any assistance or information is needed, a letter addressed to the honorary secretary, Mr. Marcus Adams, 83, White Knights Road, Early, Reading, will, I am sure, receive his courteous attention.—Yours faithfully,

LANO SIMS,
General Secretary.

THE POSITION OF PHOTOGRAPHIC SOCIETIES.

To the Editors

Gentlemen,—On the actual subject of this discussion we have nothing to add to our previous letter. We should, however, like to assure "L. P. W.," whose letter you published on January 21, that the details he gives of our origin are quite correct. At first we were composed of the president and his more enthusiastic pupils—a group of keen workers led by an expert, which is precisely the base on which one would suppose any photographic society would be built. As to the future, we hope by adapting our methods to changing needs we shall continue to grow and keep our members interested. We must apologise for thrusting these comments about ourselves into a correspondence which we were hoping would develop along lines likely to be of material assistance to any societies in the "moribund" condition described by "Fuller Hope."—Yours faithfully,

The Catford Camera Club,
F. COLEMAN,
Hon. Sec.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent. International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

G. B.—The makers of the metal frames known as "Arco" are Messrs. Whitehouse, Willetts & Bennion, Ltd., Tything, Worcester.

G. & Co.—A 10-inch lens of *f*/5.6 to *f*/6 aperture should be satisfactory, and practically any of the anastigmats of this aperture by leading makers should serve your purpose.

A. B.—(1) Certainly send in your bill when the print is published. (2) Presuming that you have definite permission, preferably in writing, you follow exactly the same course as regards charging for the right of reproduction granted by *you*.

K. B.—We think you will have to write to the original publishers of the "American Annual." Messrs. Murphy, of New York. Still it might be worth while trying Messrs. W. & G. Foyle, Ltd., 121-123, Charing Cross Road, London, W.C.2.

A. D.—You should apply to the Magna Gelatine Plate Co., 2, Eastborough, Scarborough, from whom you can get a little sixpenny book containing formulæ for developing-fixing. The company supplies the sensitive material, though whether in reels we do not know.

H. E.—In the absence of dimensions it is not possible to speak with certainty. If the side-light is 12 or more feet in height it will answer very well. The obstruction caused by the end walls if the glass were carried in depends on the length of the studio. As to cost of alterations you must consult a local builder.

C. K.—Put a teaspoonful each of olive oil and vinegar in a saucer and dip a soft piece of flannel in the mixture, rub gently on the frame and polish till quite dry with a soft clean duster. If there is any pattern use a very soft brush to finish polishing. This will take off the smoky look, but will not give a "treacly" surface like a varnish would.

C. L.—If you are limited as regards candle power probably engineer's tracing cloth would be a more suitable diffuser than paper or muslin. We should think, from what you tell us, that a single half-watt lamp of about 1,000 c.p. would be the best for your purpose. You can hardly do with less, but one lamp of this power is quite satisfactory for single figures.

W. R.—Aluminium is about the worst metal for a tank containing an alkaline solution such as a developer. Nickel steel is perhaps the best material, though somewhat difficult to work. We should not advise copper for a solution containing ammonia, although for almost all other photographic solutions it is quite the best for the purpose. Personally, we think a well-made hardwood tank is better than any of metal.

E. C.—A 7-inch lens (your No. 3) is about the best focal length for such an interior subject. You will probably need to use it at from *f*/8 to *f*/16 aperture. Difficult to say how much powder you would need, but probably, if the walls are of dark colour, ½ oz. would not be too much. If you have not a lamp, the powder should be laid in a train in some shallow metal trough of about 18 inches length, firing it by means of a piece of touch-paper or a tuft of gun-cotton placed about midway in the train.

W. T.—If, as we understand you, the camera extension, diaphragm aperture and other conditions, remained the same for the exposure of both the 8½ x 6½ and 24 x 18 plate, then obviously there is no cause, connected with these factors, for the difference in the light-action on the plate. It is not unknown, of course, for plates of the same batch number to vary in speed, but yours appears to be a regular occurrence, so can hardly be put down to that. So far as we can judge from the particulars given there is nothing to account for the difference.

A. W.—The double-pose photographs are very simply made by arranging the model against a dark background and exposing the plate twice, the model meanwhile moving over from one side of the background to the other. If you want any background other than a dark one, then you must use a shutter on the lens in form like a pair of opening doors, making one exposure with one door open and the other with the other door open. We think you can still obtain from some of the dealers a shutter for this purpose, but it is not a difficult matter to make one.

J. B.—(1) You might try easing the leaves of the iris with a little very thin oil, such as is sold for the lubrication of typewriters. But it is a rather delicate job, and you can easily damage the iris by using any force. We should think it is a case for having the iris overhauled, say, by Messrs. Fairbrother & Bowen, 9, Farringdon Avenue, E.C., which is a firm specialising in these kinds of repairs. (2) We have no doubt that at *f*/16 of *f*/22 the lens would cover a whole-plate quite well enough for groups, but we do not think you would be satisfied at larger apertures. The lens of the same series for whole-plates has a focus of 10½ inches.

W. A.—(1) There is no view-finder which you can fit to a camera which will provide a reliable means of keeping the subject in focus on the ground-glass after the dark-slide has been inserted. The only means of doing that with any degree of certainty is with a reflex or a twin-lens camera. (2) Yes, some wood, and particularly new wood with a good deal of resin in it, is liable to fog plates and in some cases to make them insensitive. We expect the wood you have is old and probably is free from this defect, but you could easily make sure of it by painting it with a fairly strong solution of permanganate and allowing it to remain in bright light, sunlight if you can get it, for a day or two.

Contents.

SUMMARY.

Regular receipt of the Continental photographic journals having been re-established, we are able to revive the "Foreign Notes and News," which in pre-war days were a regular feature. The first instalment contains notes on panchromatic sensitisers, bromoil, light-sensitiveness of collodion and colour toning with colloid silver. (P. 77.)

The incorporation is announced of Amalgamated Photographic Manufacturers', Ltd., formed by the fusion of the Paget Prize Plate Co., Ltd., Rajar, Ltd., Marion and Co., Ltd., Marion and Foulger, Ltd., A. Kershaw and Son., Ltd., the Kershaw Optical Co., Ltd., and the Rotary Photographic Co. (1917), Ltd.

The new company has an authorised share capital of £1,100,000, and is offering cumulative participating preference shares to the amount of £250,000 for public subscription. (P. 79.)

Other particulars of the amalgamated firm, of which Messrs. Gerald Bishop, of Marions, and C. F. S. Rothwell, F.C.S., of the Rajar Co., are joint managing directors, will be found on page 83. It is proposed to equip an existing factory of Messrs. Kershaw's at Leeds for the manufacture of popular plate and film cameras.

The Honble. Sir Charles Parsons, K.C.B., F.R.S., has acquired a controlling interest in Ross, Ltd. Mr. John Stuart, C.B.E., remains on the board. (P. 86.)

In a leading article we trace the stages through which the use of quinone in toning and intensifying has passed, following the first suggestion of it by MM. Lumière in reference to the hitherto unexplored field of the employment of organic substances for such purposes. (P. 74.)

Mr. A. Lockett gives some interesting particulars of the application of lens aberrations in the making of decorative patterns. (P. 76.)

In a contributed article Mr. Arthur G. Willis describes a simple scheme for discovering the direction in which studio practice, as regards exposure or development, can be improved. (P. 75.)

A reduction is announced in the price of half-watt lamps. (P. 86.)

Time-saving hints on the use of printing boxes are given in an article from "Rajar Trade Notes." (P. 80.)

A hand-drawn miniature, almost entirely monochrome, is something of a novelty in this style of portrait. (P. 74.)

Development in a tank with a specially weak solution is often of great advantage in the making of view negatives. (P. 73.)

Methods devised for the making of platinum mirrors are described in a recent patent specification. (P. 81.)

Mr. Chapman Jones is to deliver a memorial lecture on the work of the late Sir William Abney. (P. 81.)

Formulæ for warm tones in the development of lantern-plates were given by Mr. B. C. Wickison at Croydon. (P. 85.)

EX CATHEDRA.

Amalgamated Photographic Manufacturers Ltd.

The firms whose amalgamation into this company is announced are evidently following the example of many concerns engaged in such various industries as chemicals, engineering, glass and textiles. A prominent motive in consolidations of this kind is a reduction of the cost of selling goods; and we understand that this consideration applies in large measure in the present instance. The individual user in this country may perhaps think the means out of proportion to the end, but in overseas business, which is an important matter to all photographic manufacturers, a conjunction of interests has come to be an almost necessary condition of personal and adequate representation in foreign countries. What one firm alone could never afford to do at all, a union of firms can undertake at an economic rate. And as the volume of foreign trade is a factor which largely determines moderate home prices, it may be thought that the amalgamation, instead of being a movement to maintain or increase prices, as some may readily be disposed to regard it, has as an object the reduction of prices; or at any rate, the avoidance of their further elevation.

* * *

Stand Development and Contrasts.

Those photographers who sometimes undertake local view work will be aware that it is desirable that any cloud forms existent at the time of making the exposure should be retained in the original negative, in preference to printing in clouds separately. It is not an easy matter in the case of subjects containing the delicate high-lights of cloud forms at one end of the scale and deep shadows of trees or buildings at the other, to retain the clouds, while at the same time full printing detail is obtained in the shadows. Many photographers are not aware what a real help stand development, with a very dilute solution, can be in cases like these. Only the other day we were shown a negative that included the most delicate of cloud forms, though with full detail in its deep shadows. Subsequent conversation elicited the fact that the photographer used plates of the "anti screen" variety, and gave a full exposure. Stand development, with a very dilute solution, ensured the retention of the gradations of the high-lights, while the shadow detail was fully brought out. Ordinary development, with the normal strength solution, would have clogged up the high-lights long before the requisite density was obtained. The correct rendering of high-lights and deep shadows upon the same plate is, at the best, from the technical point of view, a compromise, but the stand method of development provides the finest results in cases like this. The hint may prove of value, not only to the outdoor worker, but also to the portrait or commercial photographer, when encountering difficult lighting and contrast in his subjects.

Monochrome Miniatures. We have recently seen some old miniatures drawn upon ivory in a sepia tint with the cheeks and lips indicated in colour, which would seem excellently adapted for imitation by photography. The ordinary miniature, if well coloured, is an expensive luxury, and unless the work is really well done is not acceptable to discriminating patrons. The tinted sepia on the other hand has a refined appearance and calls for little hand work. The ordinary warm sepia is not a suitable colour; a cold sepia or brown, of which several tints can be obtained, is very much better, even a warm black being suitable for some subjects. If the production of the print on ivory cannot conveniently be done at home, it is wise to entrust it to a trade firm at the cost of a few shillings. These little pictures should be shown either in the orthodox gilt rim or, what is perhaps even better, in the antique style of a square black frame with an oval opening with gilt rim.

* * *

Damp Materials. It is an established fact that dampness, even in a slight degree, is detrimental to the production of perfect results either upon plates or paper, and at the present season it is difficult to avoid it, unless a very dry and somewhat warm storage place is available. As a rule, a certain quantity of sensitive material has to be kept in the dark room, near a wet sink, and such a condition is inimical to quality. Damp may largely be avoided by obtaining an air-tight tin case—some of the Army boxes now on the market are excellent—and placing therein a perforated tin containing calcium chloride, the form used in the platinum process being the most convenient. As there is little dampness in the materials when received the calcium will keep active for a considerable time, but upon the slightest appearance of dampness it should be well dried either in a hot oven or even upon a fire shovel over a clear fire or gas ring.

* * *

Lighting Printing Boxes. Referring to recent letters upon modifying the light in printing boxes to suit negatives of various densities, a correspondent suggests the trial of an arrangement which he has found satisfactory. It is to fit as closely together as possible two or even three lamps of varying power, say a 16 c.p. carbon lamp, a 32 c.p. metallic filament and one of the smaller gas-filled or "half-watt" bulbs. A small three-way switch permits of the current being directed through any of these without interfering with the regular exposing switch, which always remains in use. The portrait photographer, whose negatives do not vary greatly, may not require such an arrangement, but for amateur work it is invaluable, as very dense or stained negatives cannot be successfully printed by a weak light, no matter how long an exposure is given. It also affords a ready means of shortening exposures with gaslight papers or weakening the light for thin negatives with bromide paper. In extreme cases waxed paper may be used to damp the light further, but this will rarely be found necessary.

* * *

Developing Tanks. Although tank development is growing in favour among professional photographers, there are still many who have given the subject but little consideration and have not grasped the difference between the amateur tank which is designed for daylight developing and the open tank which has to be used in the dark room, the type generally used for studio work. For service and economy a well-designed tank is absolutely necessary, and once such an appliance has been tried the owner will be loth to return to dish development. We are in favour of those models in which the rack is movable, so that the plates after being placed in the grooves need not be handled until they are put out to dry. It is advisable to have several extra racks, so that when a large number of plates have to be dealt with there is no delay in working. Necessarily washing takes longer than developing, and this keeps the racks out of use. If the tank is closely built and the grooves of the racks are fairly close together the minimum solution is needed, and a stronger developer than is generally prescribed may be used with a corresponding decrease in the time of development. If there are not sufficient exposures to fill the rack the solution may be kept up to its proper level by putting in a block of wood well coated with paraffin wax to fill the vacant space.

QUINONE IN REDUCING, INTENSIFYING AND TONING.

THE recent paper by MM. Lumière and Seyewetz on the use of quinone and other oxidising agents for the conversion of silver images into bromide or chloride marks the latest stage of a series of experiments, the first of which dates from more than ten years ago. Since the employment of an organic oxidising agent for this purpose represents a process which has been little applied to such photographic operations as reduction, intensification and toning, it may be of advantage to trace the stages through which it has passed. MM. Lumière and Seyewetz first drew attention to the use of quinone as a reducer of negatives in a paper[1] read before the International Congress of Photography at Brussels in August, 1910. They found that certain quinone bodies in acid solution act as reducers, giving effects similar to that of persulphate. The bath found most suitable was the following:—

Benzoquinone	5 gms. ...	45 grs.
Sulphuric acid	20 c.c.s. ...	3 drs.
Water	1,000 c.c.s. ...	20 ozs.

This is a solution of clear yellow colour at first, becoming brown in time, even in the dark, and then depositing a brown precipitate. It does not act on the negative at once. After some minutes, apparently after the solution has penetrated the film completely, the action commences, the denser parts being reduced before the lighter tones. The action is arrested by rinsing water and then placing the plate in 20 per cent. soda sulphite solution. This bath also dissolves the silver chloride which is formed in the film from the presence of chlorides (sodium chloride) in the wash water. So far as our knowledge goes, the quinone reducer, however, has never come into widespread use as a substitute for persulphate, although Stenger and Heller, in a paper in "Photographische Rundschau"[2] confirmed the French experimenters' observations as to the proportional reduction, in the persulphate manner, through a scale of densities, and further showed that an effect more akin to that produced by Farmer's reducer was obtained by cutting down the period of action or by increasing the proportion of sulphuric acid. Stenger and Heller also showed that by addition of chlorides to the reducing solution in small proportion, such as about .02 per cent., the action was almost exactly similar to that of the hypo-ferricyanide reducer of Farmer.

MM. Lumière, in a subsequent paper,[3] extended the application of quinone to intensification and colour toning. They pointed out that benzoquinone, as also its sulphonate, in conjunction with a bromide or chloride acts as an intensifier of the silver image. The plain quinone

2. "B.J.," Dec. 29, 1911, p. 989.
3. "B.J.," Dec. 16, 1910, p. 949.

compound gives greater density than the sulphonate; and bromide, better results than chloride. The following are the formulæ recommended for intensification:—

QUINONE.

Quinone	5 gms.	...	44 grs.
Potass bromide	25 gms.	...	220 grs.
Water	1,000 c.c.s.	...	20 ozs.

SODIUM QUINONE SULPHONATE.

Sodium quinone sulphonate...	10 gms.	...	90 grs.
Potass bromide	25 gms.	...	220 grs.
Water	1,000 c.c.s.	...	20 ozs.

This solution forms a single intensifying or toning bath. The image produced by it has a slight general opacity which disappears on immersing the plate, after a brief rinse, in a solution of ordinary ammonia of 10 per cent. strength. The quinone sulphonate gives a more yellowish and less intense action, and the first formula is preferable to the second, although the former has a slight sharp odour whilst the second is odourless. The intensifiers also exert a strong hardening action on the gelatine film. MM. Lumière pointed out that the intensification produced with this single solution is of considerable degree and is practically permanent, the intensified image only browning slightly under the prolonged action of direct sunlight. They also indicated the variations in the colour of the deposit which may be produced by the use of other subsequent baths than ammonia. Sodium or potassium carbonate, hypo, sulphite or bisulphite, and diamidophenol developer form baths which can be used for this purpose and permit of a distinct variety of tones being obtained. The process in this form is an excellent one for the toning of lantern-slides, the amidol bath yielding a fine purple-brownish black. At one time we made a great many lantern-slides in this way and were exceedingly pleased with the agreeable and rich tones. One of the best was obtained by following the quinone toner with a weak bath of ammonium thiomolybdate, which at that time was on the market as a solution sold as a substitute for sulphide. One recommendation of the process, which particularly appeals to makers of lantern-slides, is the avoidance of mercury compounds which, under the heat of a high-power projection light-source, are liable to undergo changes leading to the disfigurement of the transparencies The process of employing quinone for these purposes of intensification and toning was protected by patent by MM. Lumière.[4]

The use of quinone in intensification and toning was carried a stage further by Mr. John Goulding,[5] whose contribution, we must confess, we had unfortunately overlooked in adding a note to the paper in our issue of January 7 last. MM. Lumière first used quinone with acid as a reducer; then with bromide as an intensifier or toner. Mr. Goulding carried the process a stage further by employing quinone in conjunction with hydrochloric or hydrobromic acid as a bleacher. He pointed out that a mixture of quinone and hydrobromic acid allows of a stainless bleached-out bromide image being obtained from an ordinary black bromide print. The image can be treated in any of the customary ways, such as re-development or treatment with sulphide. And he further emphasised the advantages of quinone in the shape of its tanning action on the gelatine and its freedom from tendency to stain the high-lights. It will thus be seen that when employed in this way quinone is comparable with the many formulæ, such as ferricyanide and bromide, bichromate and chloride, or bromide, in presence of an acid, which serve to convert the silver image into a haloid compound. The interest of the question, and one that has been further set forth in the most recent paper by MM. Lumière and Seyewetz,[6] is that in this application of quinone we have a solitary example of the use of an organic oxidising agent for the conversion of the silver image into bromide or chloride; and in a form which is suitable for practical purposes. It is, however, hardly conceivable that there are not many other organic bodies which may perform this same function and may possess advantages of one kind or another not exhibited by quinone.

A PRACTICAL EXPERIMENT.

Most photographers are at present suffering from a "slack period," and it seems likely that the same state of things will continue until either prices drop considerably (a very distant prospect) or until the general level of photographic work is raised far above its present standard. It may therefore be an opportune moment to suggest to my fellow professionals a simple series of experiments, which, if carried out intelligently, can hardly fail to lead to a notable improvement in their routine work.

Since Studio work remains the backbone of most businesses, my remarks will be confined to that class of negative; but it will be perfectly clear that the same method of procedure will give equally valuable results in any other branch.

Without the least doubt the reason why so many of us fail to obtain satisfying results in the studio is that we do not really know the results of variations in exposures and development. The general facts, that short exposures give dark shadows and long development blank high lights, are pretty generally accepted, but unless one has investigated the matter by means of practical and systematic tests it is almost impossible to realise the more subtle, but none the less important effects of differences in treatment within what is known as the latitude of the plate.

As you are a practical worker, you have probably a decided aversion to "plate curves," "opacity logs," and the other stand-bys of the plate makers. You want to know, in short, how various things are going to effect your results. Very well, at the cost of one dozen plates you can get the finest possible lesson in photographic practice you could desire.

Get a patient assistant into the studio, light him according to your usual practice (a fairly contrasty head and shoulders is best perhaps), and fire away a dozen plates, as follows:—

We will suppose that under the circumstances of the test you consider 4 secs. as the normal exposure. First of all, then, expose six plates at this, with as little difference as possible. Make these plates A, B, C, D, E, and F. With the remaining half-dozen plates make a series of graduated exposures, say—½ sec., 1 sec., 2 secs., 8 secs., 16 secs. and 32 secs. Number these 1 to 6, and you are then ready to develop.

Let us suppose 8 minutes to be your normal time for development (whether you use dish or tank does not matter). The second series of exposures, those numbered 1 to 6, should be developed together for the normal time. The first series, A to F, having had the same exposure, should be developed for various times; with the 8 minutes standard a useful series will be 5, 6, 7, 8, 9 and 11 minutes.

You now have a dozen negatives as follows:—

Plates	A. B. C. D, E. F,	
Exposure 4 secs. ...	5. 6. 7. 8, 9. 11,	Development in minutes.
Plates	1. 2. 3, 4, 5, 6,	
Exposure in secs. ...	½. 1. 2. 8, 16. 32	Development 8 minutes.

Make no attempt to judge the results by the look of the negatives; send the whole batch to the printer with instructions to get the best possible from each negative on your standard paper. Have the prints marked to correspond to the negatives when they are made, otherwise you may have trouble in sorting them out.

You now have a most valuable series of prints. Let us examine them, and see what practical points they bring to light.

The first point to decide is if print D, that is, from the negative made with your standard exposure and development, is the best. Now I have introduced this series of tests to a number of photographers, and the proportion of "standard" prints which proved to be the best has been remarkably small. In my experience, it is usually print 5 or print C which proves nearest the ideal, that is, one with either more exposure or less development than the normal. It is obvious that, as the trials are systematic, it is easy to see what adjustments are advisable in your standards.

The most striking point in these tests is that although the variation in development is only 5 to 11, and that of exposure is ½ to 32, yet the former has the greater influence on the results. In fact, a difference of six times in the exposure may be hard to trace in the print, but so small a difference as one-sixth of the total time of development will be apparent at once.

This is fortunate, as development is under much more complete control than exposure, and can be made absolutely definite, while exposures, in the studio at least, can be obtained quite near enough to correct to give you a perfect negative very time.

It is more than likely that when examining the negatives side by side with the prints you will find that it is not your ideal negative which gives the best print. The best print usually comes from a somewhat "flat" looking negative, and since prints, not negatives, are your object, you will do well to adopt the new type as your normal.

A thing that will at once strike the keen worker about the set of prints is that the more exposure the negatives receive the less retouching they need. By making a difference of a couple of seconds in exposure you may save 50 per cent. of your retouching. This is not "theory," but a solid, business fact.

Time development is certainly the most practical for really big batches, and it can be relied on to get a very good average of good results. But there will be many who, like myself, like to see the negatives "come up." It is undoubtedly an advantage in one way to work with a dish, any difference in exposure being obvious at once, and therefore may be corrected before much damage has been done. Personally, I use the factorial method for all studio work (having various factors for the different types of lighting), and find it ideal.

If development is judged by inspection, and the trials have shown a new standard to be desirable, it is a useful tip to bind up your standard with tissue paper of such thickness that the high lights are of the same opacity as those of an unfixed negative. This will assist materially in obtaining uniform results.

In conclusion, I should like to suggest that when these tests have proved their value, as I am sure they will do, it may be worth while to make a similar, but less extensive series of negatives with other lightings. The ideal negatives for "sketch" and Rembrandt lightings, for instance, are absolutely unlike, except in their ability to give good prints, Always judge by prints, as the best negative is the best printer.

It may be objected that tests made in such a rough and ready way are valueless. To the scientist they may be, but to you, who want to know practical facts, they will prove the best invested dozen plates you have ever exposed.

ARTHUR G. WILLIS.

LENS ABERRATIONS USED IN DESIGNING.

It is well known that a simple uncorrected lens is subject to a number of optical defects, the most evident being chromatic aberration, whereby objects tend to be shown with a fringe of colour. Few, however, are acquainted with the fact that these faults are capable, in certain circumstances, of producing very beautiful patterns and designs.

This can be demonstrated with an ordinary reading glass, a metal-filament electric bulb, and a sheet of white cardboard. The writer used a bi-convex glass of 6 ins. focus and 2¾ ins. diameter, in conjunction with a 60-watt Osram lamp of the usual pear shape, run on 205-volt alternating current. The bulb should be brought within a short distance of the table by means of an adapter and flexible wire connection. With a lens of the focus stated, about 26 ins. from the bottom of the bulb to the table will be found most suitable.

On holding the reading glass in an horizontal position about 5 ins. from the bulb, with the white card directly underneath, as shown in fig. 1, an exquisite feathery design with a dark centre and blue spots, edged with tints of orange and red and shaded with delicate pearly greys, will be seen. This, of course, is a greatly aberrated and out-of-focus picture of the numerous incandescent filaments, viewed end-on.

On tilting the lens away from the horizontal, moving it out of the centre, or varying its distance from the lamp, many different patterns will result. Fig. 2 is an attempt, with some artistic licence, at recording one of these, though the drawing necessarily conveys little idea of the filmy softness and brilliant colouring of the original.

At a certain distance of the lens the design resembles a sun-

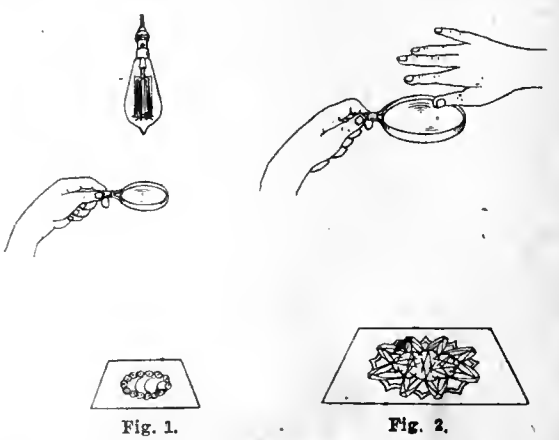

Fig. 1. Fig. 2.

flower, at another a dahlia is suggested. In some positions the minute veining and gauzy shimmer of a butterfly's wing will be indicated, or prismatic feathers worthy of a humming bird.

Obliquely used, the lens will produce strange, weird shapes which, if photographed, might readily pass for spirit pictures in psychical circles.

If the fingers of one hand are spread open and held above the lens, between the latter and the lamp, as seen in Fig. 3, the pattern increases in complexity and becomes of a more star-shaped character. On moving the fingers to and fro across the lens the design will change and coruscate, something after the style of the old lantern chromotrope. A few narrow strips of cardboard laid across the lens like bars may also be used to vary the device.

For a more leisurely inspection of the patterns, it would be easy to make some kind of stand to support the lens, with provision for adjusting it at any desired distance or angle.

The designs possess a blended softness which, though an added beauty in itself, renders them difficult to copy by hand, but the artist or draughtsman should be able to gather many hints of dainty outline and subtle colouration by studying them attentively. If the lamp were mounted horizontally and the reading glass vertically, so that the image could be thrown on an upright screen of finely-ground glass placed a suitable distance in front of the camera, it should be possible to obtain colour photographs of the patterns, by working from the back.

The result is much improved by affixing an opaque disc of card or paper, about 2 ins. in diameter, over the centre of the lens, which reduces the spherical but increases zonal aberration, and also heightens the colour effect. It may be pointed out that the late Professor Silvanus P. Thompson treated the subject of zonal aberration exhaustively in the Traill Taylor Memorial Lecture for 1902 (see "B.J.A.," 1903), but he naturally dealt with a point source of light (an arc lamp),

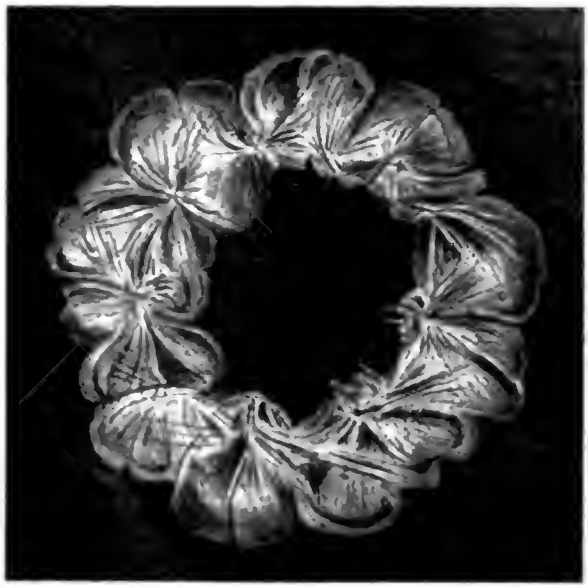

Fig. 3.

which, though giving many interesting and curious figures, does not lend itself to decorative designs like a multi-filament bulb

A. Lockett.

FOREIGN NOTES AND NEWS.

Panchromatic Sensitising Dyes.

In a recent note in the "Bulletin" of the French Photographic Society MM. A. and L. Lumière and H. Barbier describe the properties of a new series of dyes for colour sensitising which have resulted from experiments previously made by M. Barbier and communicated to the Paris Chemical Society. These dyes have been obtained on the one hand from the cyanine group of which ethyl red, pinaverdol and others are members, and, on the other, by prolonged boiling of an alcoholic solution of a mixture of di-methyl-amino-benzaldehyde with an iodo-alcoholate of quinaldine or lepidine in the presence of a condensing agent such as piperidine. The dyes thus contain one or two dimethylamino or diethylamino groups. A large number of the dyes have been prepared and tested, the most notable among them appearing to be one to which the name "Pantochrome" has been given. This sensitiser is obtained by the condensation of iodo-ethylate of dimethyl-aminoquinaldine with dimethylamino benzaldehyde. It is found that its absorption spectrum contains two bands from 490 to 530 and from 660 to the end of the spectrum. Its spectrum sensitiveness shows a maximum about 480, and then a remarkably even band from 520 to 630, with progressive fall to the limit of the visible red. "Pantochrome" thus sensitises for the whole spectrum, whilst exhibiting a small minimum about 500.

The Bromoil Process.

A recent issue of the "Bulletin" of the Belgian Photographic Association contains an abridged translation of papers by Professor R. Namias in "Il Progresso Fotografico" on recent improvements made by him in the technique of the Bromoil process. Signor Namias repeats the bleach formula which he has found satisfactory, viz.:—

Copper sulphate cryst.	10 gms.
Potass bromide	8 ,,
Chromic acid, pure cryst.	1 gm
Water	1,000 c.c s.

As regards inks, their composition should be solely of lithographic varnish, pigment and dammar resin. An ink of this kind, softened, if need be, by means of a little litho varnish, allows of excellent results provided that a paper of good quality is used. As the ink keeps well only in a sealed metal tube, it is convenient to make it up of a somewhat greater degree of fluidity for convenient filling of the tubes. This may be done by adding a volatile solvent such as essence of turpentine, toluene or benzene. In this case, after the ink has been spread on the pallette, sufficient time should be allowed for the solvent to evaporate completly. Turpentine requires about half an hour; benzene or toluene only a few minutes.

The qualities emphasised by Namias for a bromide paper for Bromoil printing are:—(1) Hard and well-sized paper base. (2) Emulsion rich in silver and gelatine, and somewhat thickly coated. (3) No hardening substances to be introduced in manufacture, and (4) opacity of the sensitive film. According to Namias, the bromide paper which best fulfils these conditions is that issued as "Bromoil" by Messrs. Illingworth.

For swelling, Namias describes a new method yielding better results than the ordinary process. It consists in subjecting the paper to the action of water, so that only the gelatine film is wetted. The print is secured to a sheet of glass by means of a 10 per cent. gelatine solution, or with a mixture of one part commercial fish-glue and five parts of water, to which is added, after the glue has been allowed to stand for some hours in the water and then dissolved by the aid of heat, 300 c.c s. of denatured alcohol. The mixture should be cooled before the alcohol is added, but the adhesive is warmed on a water bath immediately before use.

The bleached fixed and washed Bromoil print is made surface-dry with filter paper, and the back then coated with the 10 per cent. gelatine solution or with the above fish-glue mixture, the print being fixed to a slightly larger sheet of glass and left to dry. When dry it is swollen to the usual

way or by means of the following mixture, such as is employed in collotype:—

Water	100 c.c.s.
Glycerine	100 c.c.s.
Ammonia	4 to 10 c.c.s.

The advantage of this bath is that the gelatine film does not dry during inking. After inking, the glass plate, with the inked print attached to it, has only to be immersed for a short time in cold or tepid water in order to remove the print.

Measuring Gloss or Mattness.

Herr K. Kieser has described in the "Chemiker Zeitung" a method and instrument for rating the surface, as regards gloss, or mattness, of photographic papers. The process is based on the property of rectilinear polarisation of light. The degree of gloss is measured directly by the angle of rotation of the analyser of a Martens polarimeter. The surface to be measured may be slightly coloured, a somewhat bright colouration increasing the degree of gloss, apparently in correspondence with the proportion of black in the colours. Highly glossy photographic papers yield, by this method, a value of 30 deg., equal to that of glass. Those of semi-glossy surface yield a figure of about 20 deg.; matt papers, about 10 deg. In the case of papers of dead matt baryta surface, the figure may be as low as 1 or 2 deg. Uncoated papers of fine surface are rated at from 3 to 12 deg. The instrument for these measurements has been made by Messrs, Schmidt & Haensch.

Light-Sensitiveness of Collodion.

Dr. B. Homolka, in a paper in "Photographische Korrespondenz," deals with the phenomenon of sensitiveness to light possessed by pyroxyline, as observed many years ago by Gladstone and Hofmann. The action of light is to liberate extremely minute quantities of nitric acid. The reaction which takes place requires the use of a highly delicate test for nitric acid, such as is now available in the substance 9-aminophenanthrene. By the use of this reagent the decomposition of collodion in sunlight, with formation of nitric acid, can be quickly and plainly shown. If a sheet of baryta paper, coated with a collodion film containing this substance, is exposed under a negative, a positive of red colour is immediately obtained, and may be fixed by dipping in benzene in which the aminophenanthrene is soluble, whereas the compound formed from it by reaction with nitric acid, viz.:— 9-9¹-azoxyphenanthrene, is insoluble.

This experiment can be made as follows:—A mixture is made of 10 c.c.s. alcohol and 10 c.c.s. ether, in which is dissolved 1 gm. of 9-aminophenanthrene and 0.2 gm. of citric or other non-volatile organic acid. The filtered solution is mixed with 20 c.c.s. of 4 per cent. collodion and coated on baryta paper. Exposed under the Chapman Jones plate in diffused bright light for a minute or a minute and a half, a red positive print is obtained, and can be fixed by one or two successive dips in benzene.

The experiment may be done in a different way, allowing of the production of a visible from a latent image. The baryta paper is coated with a pure collodion film without addition of the aminophenanthrene and, when dry, exposed under the negative. No visible change is produced, but a kind of latent image, owing to the greater or less loss of nitric acid by the collodion film in the exposed portions. If the exposed sheet is saturated with a solution of aminophenanthrene in benzene and again exposed after drying, but this time under a clear glass plate instead of a negative, there appears a negative in red, that is to say, a duplicate of the scale of tones used for the original printing. The experiments show that the decomposition of collodion in sunlight comes within the possible conditions of print-out processes, and cannot be neglected. While perhaps its photographic importance is limited, the phenomenon provides an interesting comment on the use of collodion for the protection or decoration of metal articles. Owing to the production of nitric acid by exposure to light, the collodion coating may give rise, in a much worse form, to the very evil which it is intended to prevent.

Warm Tones with Colloid Silver.

In "Photographische Rundschau" Dr. Felix Formstecher has a paper on the production of prints in a range of warm colours by suitable (chemical) reduction of a silver chloride image. He recalls the process in which such results are obtained by restrained development of a gelatino-chloride emulsion and prescribes a method based on the conversion of a developed image into chloride and its subsequent exposure to light in presence of reducing agents appropriate to the production of tones ranging from blue to red chalk. The tones thus obtained are much more vivid in colour than those resulting from the sulphide process and others dependent on the conversion of the silver image into a different metallic compound. The mixture found most suitable for the conversion of the developed image into chloride is:—

Copper chloride	30 gms.
Hydrochloric acid, sp. gr. 1.17 ...	3 c.c.s.
Ammonium persulphate	10 gms.
Water	1000 c.c.s.

This causes the image to disappear completely, other bleachers, such as ferricyanide and mercuric chloride, leaving a faint visible residue. The print is washed for a few minutes, treated in one or other of the following baths, and exposed to light:—

For red to yellow colour:—

Stannous chloride	10 gms.
Hydrochloric acid, sp. gr. 1.17 ...	1 c.c.
Water	100 c.c.s.

The print should not be washed after exposure to light; the stannous salt may remain in it without ill effect.

For blue colour a solution of hydrazine sulphate is used, but prints must be washed after immersion in it, otherwise they turn yellow.

Hydrazine sulphate	10 gms.
Water	500 c.c.s.

Nitrite yields a colour intermediate between those produced by the two foregoing baths:—

Potass nitrite	10 gms.
Water	500 c.c.s.

Papers coated with unripened chloride emulsion are most susceptible to this process. Gaslight papers, as a rule, are more suitable than bromide, and yield good results, particularly with hydrazine and stannous chloride. With some chlorbromo paper the hydrazine is found to yield a remarkably bright colour, but the print must not be left too long in the bath, otherwise the tone becomes degraded with black in time. Washing out the hydrazine sulphate scarcely affects the tone; and with some gaslight papers the process yields a violet blue tone scarcely obtainable in any other way. With stannous chloride, on the other hand, the tone is red-chalk, becoming brownish purple. Both tones are fairly permanent.

A necessary precaution in the use of the process is to avoid too strong a light when bleaching and treating in the subsequent bath. The prints should be handled and dried in a darkened room, and not exposed to bright light until dry. If so exposed whilst wet, spotted points with yellowed whites are obtained. The process leads to a certain loss of contrast, though this can be avoided by omitting the persulphate from the bleach, which then leaves a slight residual image. Dr. Formstecher does not anticipate extensive use of the process, owing to the time required for exposure, but puts it forward as the most convenient method for the special purpose of obtaining vivid tones. The process, of course, is not new (cp. Gamble and Woolley, "B.J.," December 26, 1913, p.p. 987-991), but the particular formulæ given above have their practical interest.

Removing Uranium Intensification.

An alternative to the use of soda carbonate or ammonia for the restoration of a uranium-intensified negative to its original state is recommended by Karl Gander in "Wiener Mitteilungen." The negative is washed by soaking in successive

changes of still water until the water shows no yellow tint after the plate has remained five minutes in it. The plate is then placed (not in bright light) in a 2 per cent. solution of silver nitrate in distilled water which is allowed to act until the negative on the glass side has no brown colour, i.e., is completely black. The plate is then washed. It is not evident what advantage this method has over the much more rapid treatment with alkali.

AMALGAMATED PHOTOGRAPHIC MANUFACTURERS, LTD.

Issue of Participating Cumulative Preference Shares.

As announced in our advertising pages this week, a fusion has taken place of seven photographic manufacturing firms, viz., the Paget Prize Plate Co., Ltd., Rajar, Ltd., Marion and Co., Ltd., Marion and Foulger, Ltd., A. Kershaw and Son., Ltd., the Kershaw Optical Co., Ltd., and the Rotary Photographic Co. (1917), Ltd.

The company formed by the purchase of these businesses is Amalgamated Photographic Manufacturers, Ltd., having an authorised share capital of £1,100,000, divided into 100,000 7 per cent. cumulative preference shares, 600,000 10 per cent. participating cumulative preference shares, and 400,000 ordinary shares, each of £1.

Of these shares, 98,000 of the 7 per cent., 322,000 of the 10 per cent., and 330,000 of the ordinary have been issued in payment to the seven vendor companies. The following table shows the terms upon which directors of the new company are being paid (in shares of Amalgamated Photographic Manufacturers, Ltd.), for their holdings in the respective vendor companies in which they hold shares :—

Vendor Company.	*Shares of £1 in Amalgamated Photographic Manufacturers, Ltd., received as purchase consideration by the directors of vendor company.*
Rajar, Ltd.	
Each preference £1 share	1 10 per cent. Pref.
Each ordinary £1 share	.487 10 per cent. Pref. + .662 Ord.
Marion and Co., Ltd.	
Each preference £1 share	.757 7 per cent. Pref. + .319 10 per cent. Pref.
Each ordinary 10s. share	1.640 10 per cent. Pref. + 2.726 Ord.
Paget Prize Plate Co., Ltd.	
Each preference £1 share	1 7 per cent. Pref.
Each ordinary £1 share	2 10 per cent. Pref. + 1.750 Ord.
Marion and Foulger, Ltd.	
Each ordinary £1 share	.345 7 per cent. Pref. + .898 10 per cent. Pref. + 1.243 Ord.
A. Kershaw and Son, Ltd.	
Each ordinary £1 share	1.254 7 per cent. Pref. + 3.263 10 per cent Pref. + 4.517 Ord.
Kershaw Optical Co., Ltd.	
Each ordinary £1 share	.270 7 per cent. Pref. + .702 10 per cent. Pref. + .972 Ord.
Rotary Photographic Co., Ltd.	
Each ordinary £1 share	6.611 10 per cent. Pref. + 7.632 Ord.

The amount payable in shares to each of the vendor companies under the said sale and purchase agreements is as follows, viz. :—To Rajar, Ltd., £200,554; Marion and Co., Ltd., £70,898; Marion and Foulger, Ltd., £41,706; the Paget Prize Plate Co., Ltd., £168,314; A. Kershaw and Son, Ltd., £218,953; Kershaw Optical Co., Ltd., £28,350; Rotary Photographic Co. (1917), Ltd., £71,216; in addition to which the Company undertake to pay, satisfy, and discharge all the debts, liabilities and obligations of the respective vendor companies as at September 30, 1920, as follows :—Rajar, Ltd., £73,869; Marion and Co., Ltd., £25,969; Marion and Foulger, Ltd., £43,467; the Paget Prize Plate Co., Ltd., £49,566; A. Kershaw and Son, Ltd., £27,784; Kershaw Optical Co., Ltd., £2,661; Rotary Photographic Co. (1917), Ltd., £56,325.

An issue to the public is now being made of a further 250,000 10 per cent. cumulative participating preference £1 shares at par, which, if fully subscribed, will bring this denomination of issued shares to a total of 572,000.

It is hardly necessary in these pages to say anything by way of description of the constituent firms of the combined company; particularly as we understand that for the present, at any rate, each will be carried on as hitherto. All of them, with the exception of the Kershaw Optical Co., which is a war-offshoot of Messrs. A. Kershaw and Sons, Ltd., are of considerable, though very different establishment. Messrs. Marion, and, next to them, the Paget Co. being among the oldest firms at present in the photographic industry. The prospectus on another page briefly signalises the manufactures most prominently associated with each, and photographers will need no reminder of the distinctive and meritorious goods of theirs, which have long been well known in this and many other markets.

Moreover, the affairs of the combined company and of its constituent concerns are to be managed by a board composed exclusively of directors of the former companies, viz. :—Messrs. G. Sidney Whitfield and L. D. Whitfield, of the Paget Prize Plate Co.; Mr. Gerald Bishop, of Marion and Co.; Mr. C. F. S. Rothwell, of Rajar, Ltd., and the Rotary Photographic Co.; Messrs. Abraham Kershaw and Cecil Kershaw, of A. Kershaw and Son, Ltd., and the Kershaw Optical Co.; Mr. H. C. Rich, of Marion and Foulger, Ltd.; Messrs. A. E. Parke and T. L. Parke, of Rajar Ltd., the Rotary Photographic Co., Ltd., and Wiggins, Teape and Co.; and Mr. F. G. Thomas, of Marion and Co., Ltd.

The chairman of this board is Mr. A. E. Parke; Mr. Gerald Bishop and Mr. C. F. S. Rothwell are joint managing directors. As set forth in the prospectus, they and certain other directors have entered into service agreements with the new company for a period of five years.

The amount of the issue now offered for subscription by the public is to be applied in the equipment of the recently-built factory of Messrs. Kershaw for the production of popular plate and roll-film cameras, for developing the sale of roll and cinematograph film, and for the general purposes of the company.

The prospectus contains a chartered accountant's certificate of the aggregate profits of the various vendor companies for the years ended December 31, 1918, and December 31, 1919, viz., £193,636 and £131,179, respectively. The aggregate profits for the nine months ended September 30 last have been ascertained at £106,961, and on this basis the average annual profits for the 2¾ years ended September 30 last are obtained as £157,009, after charging for depreciation and providing for bad debts, but before charging interest, directors' remuneration, income and corporation taxes, excess profits duty, and non-recurring items.

In estimating the future profits and dividends the figure of £36,478 is set down for excess profits duty, corporation tax, directors' fees, and salaries, leaving a balance from the above average of £120,531. Possibly the removal of excess profits duty may permit of a lower value being given to the charge just mentioned.

For the payment of 7 per cent. interest on the preference shares of this class and of 10 per cent. on the 572,000 cumulative preference shares (in which total is included the present issue) a sum of £64,060 will be required, leaving a balance of £56,471. A dividend of 10 per cent. on the 380,000 ordinary shares would absorb £38,000, leaving a sum of £18,471 for further distribution between shareholders and directors. It is anticipated that the profit from the manufacture of plate and roll-film cameras and from that of paper to be manufactured at the extensions of works not yet in operation will amount to £75,000 per annum, and with the above balance of £18,471 will be available for further dividends on the participating cumulative preference shares and the ordinary shares, and for the establishment of a reserve fund. The Articles of Association of the company provide that one-tenth of the balance, that is to say, after the payment of the fixed dividends on the preference shares and a dividend of 10 per cent. on the ordinary shares, is payable to the directors as further remuneration for their services. The remaining nine-tenths is to be applied by the directors in payment of futher dividends, as may be judged advisable, to the holders of the 10 per cent. participating cumulating preference shares and the ordinary shares *pari passu* in proportion to, and not exceeding, 2 per cent. upon the amount for the time being paid up upon such last-mentioned preference shares and ordinary shares.

Further surplus profit may be applied in payment of dividends to holders of the ordinary shares.

It will thus be seen that the preference shares which are now offered for subscription have only the prior charge in front of them of the 7 per cent. issue which at the most can claim only £7,000 from the profits. The statement of recent profits certainly shows that there is ample to pay the 10 per cent. on the preference shares of this class, and there may easily be a balance permitting the payment on these preference shares of the additional 2 per cent. by way of participation in further profits. Photographers who may have been inclined to look with somewhat envious eyes upon the profits made by manufacturers of photographic materials now have the opportunity presented to them of sharing in such profits. The prospectus states that in making allotment preferential consideration will be given to applications from customers and employees of the vendor companies. The subscription list closes on Tuesday next, February 15.

EXPOSING BROMIDE AND GASLIGHT PRINTS.

(From "Rajar Trade Notes.")

ALTHOUGH electric-light is now obtainable in most towns there are still some photographers who have perforce to use gas, or oil, for exposing bromide and gaslight papers. The question of exposure is so important that we think a few suggestions on the subject may be helpful.

Dealing first with bromide printing, we find there is a tendency amongst some printers to use an exposing light (electric) which is far too powerful, necessitating very rapid exposures. In some cases this is done to "speed up" the work, but we doubt if there is any advantage in quickness when we take into consideration the time occupied in re-printing "spoils." It is easy to make a 50 per cent. error in very short exposures, and we strongly advise printers to screen down the light, or use a lower candle-power lamp, so that the exposures average 3 to 5 seconds. Those who print in strips will appreciate the point of correct and even exposures.

Exact data as to exposure cannot be given as there are so many factors to consider, but a great deal of help can be obtained if the negatives are graded by the printer himself who should also choose the grade of printing paper. When possible the grading of negatives should be done in daylight so as to make allowance for the colour of the image. Printers will find this task very difficult in cases where, owing perhaps to a careless assistant, less than the usual amount of sulphite has been put in the pyro developer used for the development of the negatives, thus causing the image to be of a yellowish colour.

In printing by electric-light, the exposing box should be fitted with a switch which is either worked by the foot, or by the contact of the pressure pad. The switch must be of a definite make and break type somewhat similar to the ordinary house switch, but we do not recommend the type of switch that is inclined to "arc" or burn up. The exposing box should have a "spy hole" so that the printer can be quite certain of the correct action of the switch, and it also acts as a guide in counting the exposure seconds. In some towns the electric-light loses some of its intensity about the time when theatres are lighting up, and allowance must be made for this.

Printing on gaslight paper offers no difficulties to those who have electric-light, but the printer who has only gas or oil at his disposal can use daylight by fitting up a room with a simple exposing device.

A window can be blocked up completely, with the exception of a space of say 20 inches square, and against this space can be put a printing box open at the back but containing a reflector at an angle of 45 degrees.

There should also be a reflector outside the window at an opposite angle to the reflector in the printing box. The exposures should be made by a shutter similar to the roller-blind shutter.

In conclusion, we should remind our friends that the first essential in bromide printing is correct exposure, and every possible device or precaution should be used to ensure correctness. In gaslight printing, which has been prophetically described as the "contact paper of the future," there is more latitude in exposure.

Photo-Mechanical Notes.

Intaglio Printing Plates.

A PROCESS of preparing the plate for intaglio (photogravure or rotary photogravure) printing is described in a recent patent specification, No. 156,420, of Ernst Sauer, Schloss Kaibitz, near Kamnath, Post Kastl, Oberpfalz, Germany.

The object of the process is to give to printing plates any required depth by a method of printing without hand work, and also to prevent the ink being dragged out of the printing block by the roller when the ink is removed from the surface of the block by the roller.

According to the invention a printing block is formed by coating a more or less transparent material, such as "cellon," celluloid, or paper on one side with a film of chromated gelatine, 0.06 to 0.08 millimetre thick, in such a way that the gelatine adheres firmly to its support, this film of gelatine forming the printing surface. The screen plate (which has transparent lines and black dots) is laid over the gelatine film and exposed until the lines of the screen have become tanned on the gelatine, an operation which in full sunlight requires an exposure of about 3½ to 4 minutes. The screen plate is then removed and the printing plate exposed from the other side through a transparency, that is to say, the transparency is laid over the transparent support of the film of chromated gelatine, so that the light passes through the transparency and the support on to the film of chromated gelatine. During exposure the rays of light pass through those places in the transparency which let strong light through right to the upper surface of the film of chromated gelatine so that it becomes completely tanned. The less transparent places in the transparency let only so much light through that a portion of the film of chromated gelatine is tanned, and as no tanning takes place under the highly opaque parts of the transparency when the film of chromated gelatine is exposed, it follows, when the film is washed with warm water, that the front of the printing block remains level in so far that the screen lines lie at the same height all over the entire surface of the picture.

On the other hand, however, the exposure from the back of the printing plate forms a relief corresponding exactly to the picture, so that the hollows which are to hold the printing ink are formed on those parts of the picture where less light has penetrated and between the screen lines. At the upper surface of the film of chromated gelatine the screen lines are of the same width as they are in the screen plate, but are thinner in the depths of the gelatine film, because the light during the printing of the screen cannot act so intensively in the depths of the gelatine sheet. These extremely fine lines in the depths of the gelatine film are fixed in the bottom of the gelatine sheet by the exposure of the transparency from the back of the printing plate, so that they cannot fall together when the plate is washed. In consequence of the lines in the depths being thinner, they form hollows between the screen lines, which are wider in the depths of the gelatine film than at the upper surface. By this means the printing ink is retained better in the hollows of the printing block when the surface is cleaned off. In order to enable the printing block formed by the upper surface of the gelatine film better to withstand the action of the roller the surface is lightly moistened with acetic acid and then coated with a film of zapon varnish.

The following patents have been applied for :—

PRINTING.—No. 1,527. Photographic printing presses. Graphische Kunstanstalten F. Bruckmann Skt.-Ges. and H. Kühn.

PHOTO-LITHOGRAPHY.—No. 156,692. Process for the production of negatives from the originals that cannot be photographed by transmitted light, for use as patterns for photo-lithography. F. Ullman Ges.

PRINTING PROCESSES.—No. 157,216. Photographic printing processes. H. Kuhn and Graphische Kunstanstalten F. Bruckmann Akt.-Ges.

REPRODUCTION SCREEN.—No. 766. Screen for photo-chemical and photo-mechanical reproductions. Herbst and Illig.

REPRODUCTION SCREEN.—No. 156,718. Screen for photo-chemical and photo-mechanical reproductions. Herbst and Illig.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Some Practical Hints.

In almost every photographic workroom one sees some practical dodge or other for the more efficient carrying out of the work. They have usually been evolved to suit the special conditions of a particular business; many are of general application. A few are collected here. If their publication will induce others to give the fruits of their experience to their fellow workers in the same way a great many most practical hints might be made generally available.

When it is desired to dry a batch of prints quickly without recourse to spirit, an excellent tip is to squeegee lightly each print on a sheet of glass before placing it on the drying net. In this way a full two-thirds of the water is removed. It will not affect the most delicate of surfaces as long as the squeegee is used lightly.

Don't be bothered with weights for chemical of bulk, such as carbonate and sulphite. Providing you always get them in the same form, measuring can be done with quite sufficient accuracy by cutting down a round cardboard canister so that it holds the required amount. One canister for each chemical must be the rule, and it may well be kept in the cask in which the chemical is stored, so that all one has to do is to scoop up enough crystal to fill it.

If you use crystal carbonate much time may be saved in dissolving if it is crushed before being added to the water. A roughly made bag of stout, well-washed canvas and a wooden mallet are the most practical tools.

There is no need to throw away "spirit" that has been used for drying negatives or prints; it is a wasteful thing to do in these days. Add some "dry" potass carbonate to it—the water will combine with the chemical, sinking to the bottom, when the clear and dried spirit may be poured off.

When retouching by artificial light it is almost essential to have some means of softening the glare if eye-strain is to be avoided. Blue is the most restful colour to work by, but blue glass is not satisfactory as a rule. The most effective filter in my experience is a solution of copper sulphate. If contained in a thin glass flask or beaker it may be well diluted, and will give a most pleasing working light if placed just between the illuminant and the reflector.

For sharpening retouching pencils I have found a much more satisfactory surface than glass paper, that is, a fine grade hone, such as is used for sharpening small knives. It never wears out, has just the right "grip," and can be washed when it becomes much used.

ARTHUR G. WILLIS

ROYAL PHOTOGRAPHIC SOCIETY.—At the request of the Council Mr. Chapman Jones, F.I.C., has consented to deliver a memorial lecture on the life and work of the late Sir William Abney. The date of the lecture has been provisionally fixed for Tuesday, April 26.

DEATH OF REV. J. B. MACKENZIE.—We regret to hear of the death of the Rev. J. B. MacKenzie, F.S.A., minister of the Perthshire parish of Kenmore. Mr. MacKenzie, who was in his 83th year, was one of the oldest amateur photographers in the Kingdom, and had practised photographic processes from the year 1860. For a very long period he spent much of his leisure in carrying out a photographic survey of ecclesiastical remains and Celtic sculptures in the county of Argyll. His photographs, which have been deposited with the Scottish Society of Antiquaries, have frequently been used for the illustration of publications, and have served to record many Celtic carvings which have suffered very greatly from exposure to the weather.

FORTHCOMING EXHIBITIONS.

February 14 and 19.—Leicester and Leicestershire Photographic Society. Particulars from the Hon. Secretary, W. Bailey, Cank Street, Leicester.

February 19 to March 5.—Edinburgh Photographic Society. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

February 19 to March 12.—Scottish Salon, Dundee. Particulars from the Hon. Secretary, James Slater, Rosemount, Camphill Road, Broughty Ferry.

March 16 to 19.—Hackney Photographic Society. Latest date for entries, March 1. Particulars from the Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 13 to 23.—Portsmouth Camera Club. Latest date for entries March 31. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

April 15 to 23.—Professional Photographers' Association, at the Photographic Fair, Horticultural Hall, Westminster, S.W. Hon. Secretary, Marcus Adams, 83, White Knights Road, Earley, Reading.

April 15 to 23.—Photographic Fair, Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Latest date for entries, March 17. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Latest date for entries, April 16. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, January 24 to 29:

STEREOSCOPY.—No. 3,502. Means for imparting stereoscopic effect to photographic negatives, prints and projections. F. G. and J. McKim.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PLATINUM MIRRORS. No. 156,472 (September 16, 1920). Hitherto the method adopted for coating glass with platinum or other metal is to spread some viscous, usually oily, mixture containing the metal salt on the glass. After burning off, the resulting metallised surface shows a certain granularity and want of homogeneity in the structure of the metal coating, which diffuses a good deal of the light falling on it, and renders it inapplicable for many optical purposes, for instance for first surface mirrors for prisms or reflex cameras.

The improvement consists in electrically depositing a platinum salt, or salt of one of the other metals of the platinum group in a solution of collodion. The glass plates are coated with this solution, which forms a dry, structureless collodion film, which, on being brought to a suitable temperature in an electric furnace leaves an absolute mirror-like structureless metallised surface free from grain and practically free from irregular diffusion of the light impinging on it.

The collodion is prepared by dissolving any suitable form of soluble gun cotton, such as collodine or pyroxyline in methyl alcohol and then adding to it a solution, preferably in ethyl

alcohol, of the platinum salt, or the salt of a metal in the platinum group. Some of the salts suitable for the purpose are platinum chloride, chloroplatinic acid, palladium chloride, iridium chloride, chlor-iridic acid. The collodion coating mixture may, if desired, be conveniently thinned down by a further addition of ethyl alcohol. These salts may be used singly or in combination.

The temperature to which the glass is subsequently raised in the furnace will determine whether the structureless mirror surface is (1) in the form of a loose deposit, (2) an adherent deposit, (3) a deposit partially adherent and partially incorporated within the surface layer of the glass (partial burning in), or (4) completely incorporated within the surface layer of the glass (completely burnt in). These four stages are reached successively at successive increases of temperature, but the actual temperature required for each stage depends likewise upon the composition of the glass, and has to be determined experimentally. The temperature to attain stage (1) does not exceed 500 deg. C., for any kind of glass; to attain stage (4) the temperatures in general range from 600 deg. to 750 deg. C. Ordinary kinds of plate glass, for example, attain to stage (4) at temperatures from about 690 deg. to 740 deg. C., whereas for ordinary kinds of crown glass the temperatures average about 30 deg. C. lower.

In order to avoid disturbances of the glass surface itself, and to keep it as near as may be optically flat in the case of a plane mirror, or true to its curvature in the case of lenses, it is very desirable that the temperature to which any glass should be raised should be the minimum possible, and a further improvement in the process therefore consists in the addition of a very small proportion of a lead salt or a bismuth salt, preferably bismuth chloride, to the collodion solution, which enables the temperature to be reduced frequently by as much as 30 deg. C. The exact reduction of temperature achieved has to be established experimentially for every kind of glass.

The bismuth chloride solution is conveniently made up as a 5 per cent. solution in industrial spirits, adding 5 per cent. hydrochloric acid. This solution is further diluted with industrial spirits immediately before use.

A typical platinising coating mixture would be made up as follows:—

6 per cent. celloidine dissolved in methyl alcohol. 3 parts by volume.

12 per cent. platinum chloride (chloro-platinic acid) H_2PtCl_6 dissolved in industrial spirits. 3 parts by volume.

Ethyl alcohol. (Industrial spirits.) 3 parts of volume.

1 per cent. bismuth chloride solution in industrial spirits. 1 part by volume.

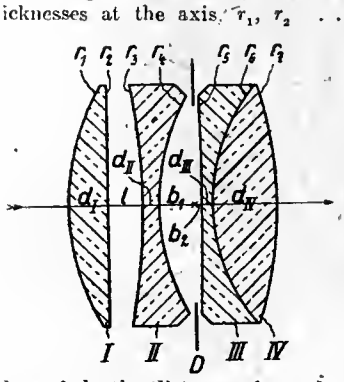
The platinised surface mirrors resulting from this process are structureless and transparent, and have a neutral grey tint. The depth of tint can be nicely regulated by varying the proportion of the platinum in the coating mixture, but it is not practicable to produce beyond a certain depth of tint in a single coaling. To increase the depth of tint, the metalised glass is re-coated and the process gone through again. It is feasible to repeat the process as often as three or four times, but in practice it is rarely necessary to give more than two coatings for fully-metalised surface mirrors, or a single coating for semi-metalised mirrors.—Julius Rheinberg, 57, Holborn Viaduct, London, E.C.1.

FOUR-LENS ANASTIGMATS.—No. 146,211 (October 15, 1917). The invention relates to spherically, chromatically and astigmatically corrected objectives consisting of four lenses, two of which are joined in a collective cemented surface, while between the other two, which are disposed at one and the same side of the cemented lenses, and of which the outer one is a collective lens and the inner one a dispersive lens, there is an air-space, and they form a pair of facing surfaces having a negative power.

The arrangement of the lenses as it is chosen for objectives of the present type, which are principally designed for the purposes of photography and projection, and which are described for instance in Patent Specification 13,061/02, is specially suitable for obtaining a spherical correction even in types with a large aperture ratio of the objective, whereby, in addition, a relatively large area of anastigmatic flatness of the field may be attained. However the obtaining of such a correction in the desired measure seemed to be possible only in the event of glass with a high refractive index being employed for the single collective lens to be made of crown glass. This restrictive condition meant a disadvantage for the objectives in so far as crown glasses with a high refractive index, as is well known, cannot easily be made homogeneous and free of bubbles, and offer little resistance to chemical influences. The heavy baryta crown glass, for instance, is such a glass, the employment of which frequently seemed necessary for the collective lens.

However, calculations made of late have shown, that it is possible to use for the single collective lens glass with a more favourable refractive index of less than 1.57, which may be done without impairing the hitherto attainable state of correction of the objectives in question. From the glasses with a refractive index of less than 1.57, such may always be chosen, as do not show the disadvantages alluded to, so that these disadvantages are at least avoided as regards the single collective lens, which as a rule will form the front lens of the objective, and which is therefore specially exposed to detrimental influences.

In the drawing, which is elucidated in the table appended below, between the two lenses marked I and II there is an air-space, and they are separated from the two cemented lenses marked III and IV by a diaphragm D, the outer lens of the two cemented lenses being a collective one and the inner lens a dispersive one. This object is to be introduced into the path of the rays in such a manner that the single collective lens faces the object. The example is spherically corrected for a relative aperture of about 1 : 4.5 and the anastigmatic flatness of the field extends to about 60 deg. Furthermore, the letters d_1, d_{11} . . . . . signify the thicknesses at the axis, r_1, r_2 . . . . . the radii



of curvature, b_1 and b_2 the distances from the diaphragm D to the adjacent lens vertices, and l the central thickness of the air-lens between the two lenses I and II. The numerals given are proportional numbers and relate to the focal length of the whole objective of 100 units. The glasses used are characterised by the refractive index for sodium light, n_D, and by the reciprocal power of dispersion γ. The numerals for the example are as follows:—

Radii.	Thicknesses and distances.
$r_1 = +\ 21.64$	$d_1 = 3.49$
$r_2 = \pm\ \infty$	$l = 3.12$
$r_3 = -\ 57.88$	$d_{II} = 1.44$
$r_4 = +\ 20.36$	$b_1 = 3.19$
$r_5 = -\ 257.18$	$b_2 = 0.25$
$r_6 = +\ 17.04$	$d_{III} = 0.98$
$r_7 = -\ 36.23$	$d_{IV} = 5.76$

NEOL.—No. 408,742. Photographic developers included in class 1. J. Hauff and Co., Gesellschaft mit Beschränkter Haftung, Stuttgarterstrasse 333, Geusrbach, near Stuttgart, German Republic, chemical manufacturers. October 15, 1920.

New Books.

Pictorial Photography in America, 1921. New York: 63, Cliff Street. J. D. Drew $3.

THIS is the second annual volume of reproductions of American pictorial photographic work produced by the body which calls itself "The Pictorial Photographers of America," and has Mr. Clarence H. White on its editorial committee. The work which it has chosen to exhibit in this way has been highly selected. There are not three-score of reproductions, but nothing has evidently been spared as regards engraving, paper, and printing to ensure a truthful transcript of their qualities. They include some delightful works; eccentricities are commendably few in number; and the globe or ball, so long the hall mark of "art" among American pictorial photographers, seems at last to have been abandoned. The literary portion of the volume does not occupy many pages. The opening feature is a review of the year's progress in the pictorial sense elicited from Mr. Clarence H. White by Henry Hoyt Moore. Perhaps we are strangers to American methods of labelling literary output of this kind, but it seems remarkable that the text should be headed "By Clarence H. White: An interview with Henry Hoyt Moore." However, Mr. Moore asks all the questions, catechism fashion, and Mr. White is ready with the answers, so why should we quarrel with the form in which their relations are stated? Mr. White thinks that the most prominent element in pictorial work is the use of the *soft-focus* lens, but with moderation; it must give softness, not fuzziness. He looks with modified approval upon what has been done with it for cinematography, but hopes for better things from this application. We are not surprised that Mr. White should take the conservative attitude of regarding photography as a monochrome art. His own sense of tone values must constrain him to that view, so that for the present he is quite content to leave colour processes out of consideration. But why Mr. Moore should intrude into this esthetic conversation a question on the value of the "Photostat" passes our comprehension. But Mr. White was not to be caught; he answered that he had only heard of it. A feature which no doubt will greatly appeal to the pictorial aspirant is a collection of short articles by those whose work is exhibited, giving the technical particulars of camera, lens, plate, and printing process concerned in their respective productions. British materials and apparatus figure frequently in these confessions, and some of the works are of truly cosmopolitan origin for example, one made in a Lancaster reflex, on a Scul plate with a Goerz lens and printed in Bromoil on Wellington paper.

R. P. S.—The group formers seem to be active in the R.P.S. It is announced that a pictorial group has been formed and will hold informal meetings on the first and the third Friday of each month at 6 p.m. Prints are to be exhibited and criticised, and discussions held on subjects related to pictorial photography. There is no doubt that such a group as this can serve a really useful purpose to many of the members of the Society. And we hear also, by a side-wind, of a dark-room group, formed in the interests of those whose chief purpose in becoming members of the Society appears to be the use of the facilities in the way of dark room and enlarging work. The extension of these facilities has recently been made the subject of a little pièce of political propaganda within the Society in connection with the forthcoming election of Council.

New Materials.

Desensitol for White Light Development. Sold by Ilford, Ltd., Ilford, London, E.

THE Ilford Company is to be congratulated in giving photographers the opportunity of making practical trial of the process of desensitising plates for development in full light, which was introduced to the notice of those in this country by Mr. Raymond E. Crowther in the article which we published in our issue of January 7 last. The phenosafranine dye, by which the sensitiveness to light of an exposed plate is reduced to a degree ranging from 200 to 800 times, has been placed upon the market in solution form which requires simply mixing with water in order to form the desensitising bath. Messrs. Ilford, Ltd., recommend the use of such a 1 : 50 solution applied to the plate for a minute or so before development in preference to the addition of the solution to the developer. The plate has simply to be soaked in this solution for a very short time either in darkness or by the light of the ordinary dark-room lamp. It can then, without any further treatment, be developed by ordinary light, which in the case of a non-colour sensitive plate may be a 15 c.p. incandescent lamp at a distance of 6 or 8 ft. With panchromatic plates a weaker light, e.g., that of an ordinary candle, requires to be used. Although the dye forms a strongly coloured solution, its action does not depend upon its absorption of actinic light. After the plate has been treated in the separate dye bath, or has remained for a minute or more in a developer containing the dye, it may be handled in light of the strength indicated above without fear of fog, and the progress of development watched just as when working in the ordinary way. The only modification in the ordinary procedure which the process involves is the washing out of the red colouring matter from the gelatine. In many cases the dye will be completely discharged by the customary process of washing, but if washing for the normal time leaves the gelatine film still stained, the latter may be cleared by soaking in a bath of

Hydrochloric acid	5 parts
Alum	2 ,,
Water	100 ,,

This is applied after the plate has had, say, at least 15 or 20 minutes' washing after fixing, and requires to be followed by a short wash in order to complete the process. "Desensitol" is supplied in 3 oz. bottles, price 2s., post free in the United Kingdom, 2s. 9d.

Commercial & Legal Intelligence.

NEW COMPANIES.

BAGSHAW, REYNOLDS AND DIX, LTD.—This private company was registered on January 31, with a capital of £10,000 in £1 shares. Objects: To carry on the business of lithographers, photographic printers, engravers, etc., and to adopt an agreement with H. S. Dix, W. W. Hull and F. E. Baddeley. The permanent directors are H. S. Dix, 51, Chatsworth Road, Croydon, Surrey; W. W. Hull, 35, Marchmont Road, Wallington; F. E. Baddeley, Lenton, Cecil Road, Cheam, Surrey. Registered office: 11, St. Matthew Street, Westminster, S.W.

AMALGAMATED PHOTOGRAPHIC MANUFACTURERS, LTD.—Amalgamated Photographic Manufacturers, Ltd., has been registered with a nominal capital of £1,100 in £1 shares: 100,000 "A" pref., 600,000 "B" pref., and 500,000 ordinary. The objects are: To acquire all or any of the businesses carried on by Rajar, Ltd., at Mobberley, Cheshire, and elsewhere, by Marion and Co., Ltd., at Southgate, at Soho Square, London, and elsewhere; by Marion and Foulger, Ltd., at Bedford, and elsewhere; by the Paget Prize Plate Co., Ltd., at Watford, and elsewhere; by the Kershaw Optical Co., Ltd., at Leeds, and elsewhere; by A. Kershaw and Sons, Ltd., at Leeds and elsewhere; and by the Rotary Photographic Co. (1917), Ltd., at West Drayton, and elsewhere; and to carry on the business

of manufacturers, exporters and importers of and dealers in photographic cameras, plates, films, papers, mounts and frames, cinematograph projectors and films, optical lenses, prisms, binoculars and optical glass, astronomical, surgical, scientific and technical instruments, post cards, show cards, advertising specialities, etc. The minimum subscription upon which the directors may proceed to allotment is 7 shares. The first directors are: A. E. Parke, Edgehill, Wadhurst, Sussex, paper maker; G. S. Whitfield, Little Cassiobury, Watford, dry plate and paper maker; L. D. Whitfield, Northlawn, Cassiobury Park, Watford, dry-plate and paper maker; C. Kershaw, 25, Mexborough Avenue, Leeds, engineer; A. Kershaw, O.B.E., Raincliffe Avenue, Scarborough, engineer; T. L. Parke, Withnell Fold, near Chorley, paper maker; F. G. Thomas, C.M.G., 115, Baker Street, W., barrister; H. C. Rich, Barsham House, Bedford, frame and mount manufacturer; G. M. Bishop, Clere, Welgarth Road, N.W.11, photographic plate manufacturer; C. F. S. Rothwell, F.C.S., Thornedge, Spring Road, Hale, Cheshire, photographic paper and film manufacturer. Qualification £100. Remuneration £250 each per annum, with £250 extra for the chairman and a share in surplus profits as shown below. The profits of each year available for distribution are to be applied (subject to provision for reserve): (1) In payment of a fixed cumulative preferential dividend at 7 per cent. on the "A" pref. shares; (2) in payment of a fixed cumulative preferential dividend at 10 per cent. on the "B" pref. shares; (3) in payment of a non-cumulative dividend at 10 per cent. on the ordinary shares; (4) in payment of 10 per cent. of the remaining profits to the directors as extra remuneration; (5) in payment of dividends to the "B" pref. and ordinary shares *pari passu* in proportion to and not exceeding 2 per cent. upon the amount paid up thereon respectively; and (6) in payment of the surplus by way of dividends on the ordinary shares. In a winding up, the "A" and "B" pref. shares take priority in order named for return of capital and arrears of cumulative dividend, and the ordinary shares take the remaining surplus assets. The directors may borrow and raise money and issue debentures or other securities, provided that the amount at any one time owing shall not, without the sanction of a general meeting, exceed the amount of the issued capital. Each share confers one vote, provided that the "A" and "B" pref. shareholders may only attend and vote at general meetings when their fixed dividends are three months in arrear or their interests are directly affected.

Wheeler, Fisk-Moore, Ltd.—This private company was registered on February 3, with a capital of £3,000 in £1 shares. Objects: To take over the business of a photographer, photographic artist, and portrait or minature painter, etc., carried on by P. S. Lankester, at 36, High Street, Tunbridge Wells, and to adopt an agreement with H. D. H. Wheeler. The permanent directors are—H. D. H. Wheeler, 7-9, Church Street, Folkestone; Grace H. Wheeler, 7-9, Church Street, Folkestone; J. Fisk-Moore, St. George's Tate, Canterbury; W. Fisk-Moore, St. George's Tate, Canterbury. Registered office: 7 and 9, Church Street, Folkestone.

Flexible Films.—A recent German patent specification, No. 154,902 (open to inspection but not yet accepted), of F. Schoepp and O. Dorendahl, relates to photographic films. As a substitute for celluloid or transparent paper, what is known in Germany as "Glashaut-papier" (glass-skin paper) or "Zellophane" (cellophane) or "Zellstoffglashaut" (cellulose glass-skin) is used. The material is obtained from viscose and forms a flexible and tough skin similar to celluloid and gelatine, and it is not inflammable.

The Prize of £1,000, offered by the "Scientific American" for the best short paper explanatory of the Einstein theory of relativity, has been awarded to Mr. L. Bolton, one of the senior examiners in the Patent Office. Mr. Bolton is a student of the scientific side of stereoscopic photography, and some years ago read a paper on this subject before the Royal Photographic Society. Reverting to Einstein, our contemporary, "Nature," in its issue of February 17 next (Macmillan: 1s.) is publishing a large number of special contributions by scientific men, dealing with the theory of relativity from various standpoints of present-day thought.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Monday, February 14.

Bradford Photographic Society. "Preparing the Exhibition Print." T. Lee Syms.
Cleveland Camera Club. Exhibition.
Cripplegate Photographic Society. "Personal Practice in Pictorial Printing." E. C. Perry.
Dewsbury Photographic Society. "The Churches of Holderness." F. Atkinson.
Glasgow and W. of S. Amateur Phot. Assoc. Competition slides.
South London Photographic Society. "Truth In and About Photography." T. H. B. Scott.
Walthamstow and District Phot. Soc. "Gum Bichromate." F. D Hunt.
Willesden Photographic Society. "A Chat on Snow Photography." S. Brigden.

Tuesday, February 15.

Royal Photographic Society. "Picture-making on the Cornish Coast." Walter Thomas.
Bournemouth C.C. R.P.S. Affiliation. 1919 Competition Prints.
Exeter Camera Club. "Satista Printing." T. W. Melhuish.
Glasgow and W. of S. Amateur Phot. Assoc. "With a Military Bacteriological Laboratory in East Africa." Dr. J. Hume Patterson.
Hackney Phot. Soc. "Bromoil." J. J. Beasley.
Leeds Phot. Soc. "A Naturalist and His Camers." Riley Fortune.
Manchester Amateur Phot. Soc. "The Production of an Illustrated Newspaper." F. G. Curson.
Portsmouth Camera Club. "Amateur Photographer" Prize Lantern Slides.
Rotherham Phot. Soc. Members' Lantern Slide Evening.
Sheffield Phot. Soc. "Lincoln." J. Tremayne Blackshaw.
Stalybridge Phot. Soc. "Car-bro." J. Kershaw.
Walthamstow and District Phot. Soc. "Pictorial Work in Grest Cities." A. H. Blake.

Wednesday, February 16.

Accrington Camera Club. "Photographic Chemistry." J. Hill.
Borough Polytechnic Phot. Soc. "Flashlight Photography." A. Dordan-Pyke.
Croydon Camera Club. "Enlarged Negative Making." R. H. Lawton, F.R.P.S.
Dennistoun Amateur Photographic Association. "The Art of Picture Making." Dan Dunlop.
Glasgow and W. of S. Amateur Phot. Assoc. Competition slides.
Halifax Scientific Society. "The D.I.P. Process." J. A. Wade.
"Self-Toning Papers." J. W. Smith.
Ilford Photographic Society. Whist Drive.
Partick C.C. "The Evolution of the Book." J. McBeth.
Rochdale Phot. Soc. "Carbon Process." A. E. Cooper.
Woodford Phot. Soc. "Picture-Making in Northern Africa." P. B. Dannatts.

Thursday, February 17.

Birmingham Phot. Soc. "Bromide Toning." E. A. Bierman.
Brighouse Phot. Soc. "Life of a Dragon Fly." W. Cliffe.
Camera Club, The. "The Ruin and Restoration of Belgium." Sir Cecil Hertslet.
Everton and District Photographic Society. "Portraiture: A Few Tips on Posing." W. Brinsley.
Gateshead and District C.C. "Negative Making." G. A. Keen.
Glasgow and W. of S. Amateur Phot. Assoc. "With the 7th Cameronians on Five Fronts." Lieut.-Col. R. Blair.
Hammersmith (Hampshire House) Photographic Society. "One Man Show." Walter Selfe.
North Middlesex Phot. Soc. "Photography—Its Present-day Importance and Power." A. Dordan-Pyke.

Friday, February 18.

R.P.S. Pictorial Group. "Hands in Portraiture." C. P. Crowther.
Bedford Camera Club. "Java: Its People and Temples."
Birmingham Photographic Art Club. "The Romance of the Gunpowder Plot." A. Clark, F.R.P.S.
Edinburgh Photographic Society. Social Evening.
Glasgow and W. of S. Amateur Phot. Assoc. Competition slidea.

Saturday, February 19.

Glasgow and W. of S. Amateur Phot. Assoc. "With Allenby through Palestine." W. Butcher and Sons.
Walthamstow and District Phot. Soc. Visit to National Gallery.

South Suburban Photographic Society.—Mr. J. W. Hodges, of Blackheath, lecturing last week, spoke very highly of the Eastman portrait films for difficult and harshly-lighted interiors. Mr. Hodges dealt first with cameras, lenses, etc., for architectural work, and afterwards showed about one hundred of his best pictures in the form of lantern slides—many of them medalled—depicting all the well-known cathedrals, abbeys, etc. The collection included a very fine series taken recently in and around Ludlow, the Kodak flat film being used for them; the results were of a particularly high quality and quite free from halation.

News and Notes.

Half-watt Lamps have been reduced in price, as from February 1. The General Electric Company's latest price list shows reductions of 5s. for the 1,500- and 1,000-watt lamp; 4s. for the 500-watt; and 3s. 6d. for the 300-watt. The respective new prices are 32s 6d., 25s., 20s., and 16s. 6d.

Pure Chemicals.—The Cooper Laboratory, Watford, have issued a price list of certain pure chemical re-agents prepared by them, consisting chiefly of indicator dyes, but including a number of pure inorganic substances, such as potass, bichromate, sodium oxalate, and sodium thio-sulphate.

L.A.P.A. Prints.—On Monday next, February 14, a collection of prints by members of the Liverpool Amateur Photographic Association will be on view at the house of the Royal Photographic Society, 35, Russell Square, London, W.C. The exhibition will remain open to the public, daily from 10 to 5, until March 14.

Cinematographic Technique.—The New York Institute of Photography, of 141, West Thirty-sixth-street, New York, is publishing "A Condensed Course in Motion Picture Photography." The volume will have special chapters by research specialists of the research laboratories of the Eastman Kodak Company. There will be many illustrations.

Ross, Ltd.—The Honble. Sir Charles Parsons, K.C.B., F.R.S., having acquired, as from January 1, 1921, a controlling interest in the old-established optical and scientific instrument firm of Ross, Limited, will shortly join the board as chairman. Mr. John Stuart, C.B.E., who has been head of the firm for over 50 years, remains on the board.

21-year Sittings.—Messrs. William Spencer and Son, of Pudsey, Yorks., have just finished an interesting series of photographs. They have taken a photograph for 21 consecutive years of a Mr. Bradley since birth to his twenty-first birthday, the exposures having been made on his birthday each year. The series forms a remarkable collection of portrait work. The prints have been mounted all on one card.

The Photographic Journal of America.—Mr. Frank V. Chambers, publisher of the "Bulletin of Photography," has taken over in addition "The Photographic Journal of America," formerly published in New York by Mr. Thomas Coke Watkins, who has had to retire through illness. The "Journal" will now be published in Philadelphia, where it was originally started as "Wilson's Photographic Magazine," by the late Edward L. Wilson, in 1864.

Paget Process Plates.—Messrs. Hunters, Ltd., 16-18, St. Bride Street, London, E.C.4, have just issued an illustrated circular descriptive of the series of Paget plates manufactured for half-tone and three-colour photo-engraving. The advantages of a dry-plate over wet collodion for half-tone work are set forth, and particulars given of the red-sensitive, green-sensitive, and process panchromatic plates made by the Paget Prize Plate Co. for three-colour reproduction. The circular is obtainable free on application.

Classical "Views" of London.—Some "Daily Chronicle" readers have been discussing the question of the spot from which the most pleasing view can be obtained, and naturally (writes a correspondent) opinions differ widely. One writer of a literary rather than a photographic turn of mind states that the finest view in London was, according to Thackeray, the Serpentine seen from its own bridge. Robert Browning preferred the Regent's Canal from Maida Vale; the view from the windows of St. Stephen's Club excited the admiration of Alma Tadema; while both Dickens and Marcus Stone selected the view of St. Paul's from Bankside (across the river). Walter Crane's ideal view was obtained from Waterloo Bridge, looking down the river, and Lord Leighton's artistic eye found most beauty in Trafalgar Square.

Mr. Henry Stevens, the present head of the eighteenth-century auction rooms in King Street, Covent Garden, has recently added a further inducement to visit these premises. He has arranged on the walls of the inner room, where goods are chiefly displayed prior to the sales, a collection of his photographs of flowers and animals. It must be nearly fifteen years since these were last publicly shown, viz., at the offices of the "British Journal." For their technical quality, and particularly in respect to their extraordinary rendering of texture, they rank with the best things ever done in photography. Mr. Stevens has rendered a service by thus reminding the present generation of what the older technicians could do — and without colour-sensitive plates, too. We understand that the photographs are to remain permanently in their present position.

Correspondence.

****Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

WARMING THE STUDIO.

To the Editors.

Gentlemen,—I have been interested in the correspondence relating to the warming of the studio, and perhaps my own experience may help undecided purchasers to form an opinion. I write as a country photographer, where electricity (unless made on your own premises) does not exist, and where gas, though procurable, does not happen to be laid on. I have tried oil stoves and various kinds of coke and coal, but at last I have hit upon the most satisfactory of all—the Methuen Sawdust Stove, which can be procured in my own town, and is now being sent all over the country. It is clean, very economical, and easy to fill and prepare each day. Another great advantage to users of wooden studios, garages, etc., it is *safe*, being completely enclosed, and can be left with confidence either by day or night. Different kinds of sawdust vary somewhat in the degree of heat given, the fine, brown kind being slightly fiercer than the coarse white, but if kept dry, either kind is satisfactory, and if one wishes, the contents of the waste-paper basket, dry leaves, or vegetable refuse can be mixed with the sawdust, and burns well. If there is a chimney already in the studio, the stove can be placed to it at once; otherwise, some piping must be put in, and will increase the heating surface. Solutions can be warmed conveniently on the top,—Yours faithfully,

Herbert Spackman.

Priory Street, Corsham, Wilts.

KEY INDUSTRIES.

To the Editors.

Gentlemen,—I have read with interest the correspondence with regard to "Key Industries," and as an old professional photographer certainly do consider that our plate makers and paper makers are taking a mean advantage of their strong position to-day. I noticed in the Press only last week that a combination had been formed consisting of a number of important photographic manufacturers with a capital of £1,000,000. This and the Kodak combination seem likely to "rule the roost" as far as the photographic trade in England is concerned, and particularly when one bears

in mind that all the rest of the English makers are of the same opinion. Worse than this, I believe that they have actually managed to get several of the big foreign importers with works on the Continent into their way of thinking, and they also have increased their prices, for they are afraid if they give an advantage to the "wee" professional photographer that the Board of Trade may do something ultimately under the head of "dumping prevention" to make business awkward for them.

In pre-war days I know that our professionals were underpaid, and it was largely our own fault that we were. We ought never to come back to the old days of insufficient pay, and I am inclined to think that the material makers are trying to raise the standard of pay for work done by keeping their prices so high. But I contend there is no need for this. They ought easily to be able to give us a 25 per cent. cut in price of materials, and there is no necessity for any of us to lower our prices at all for work done, for we cannot be considered profiteerers, even during the boom war period, as far as photographic work was concerned. Whoever heard of a professional photographer retiring in affluence? I never did, and most of us go along to a hoary old age and sometimes manage to retire in a somewhat low fashion. Sad to relate, the majority appear to die "in harness," and not too well off at that.

These notes will undoubtedly come to the notice of the secretary of the Photographic Manufacturers' Association, and will be brought before their notice, and this correspondence will probably serve to show him that we are not taking this matter "lying down," and our P.P.A., which is certainly a strong body (if it shows its hand), is in a position "to do something." They have their own solicitor, and he ought to be instructed by the P.P.A. Council to keep well in touch with our Government authorities with regard to any restrictions of imports.—Yours truly,

JOHN ROBINSON.

MATT GROUND PLATES.

To the Editors.

Gentlemen,—With reference to the letter in your columns of February 4 and signed H. Green, regarding matt ground plates, it may interest your readers to know that we have made arrangements with Messrs. Elliott and Sons, Barnet, Herts, to supply us with such an article, and, in fact, we have tested samples and found them most satisfactory indeed. They undoubtedly are a great boon, to the earnest pictorial worker especially, and we feel sure Messrs. Elliott and Sons will supply to any of your correspondents.—Yours truly,

T. BAIRD AND SONS.

71, Queen Street, Glasgow,
February 5.

FACTORIAL DEVELOPMENT.

To the Editors.

Gentlemen,—In reply to Mr. Hall's letter (p. 59), if the error in observing the "time of appearance" is caused entirely by slowness of mental decision, such indecision is for a fixed time (varying perhaps from half a second for a skilled motor driver to half a minute for a man of no active occupation) and is multiplied by the factor, giving much the least total error for a short factor developer.

But if the cause is entirely poor sight, or a poor dark-room illumination, the error will be a percentage one on the time of appearance. And as this last is short in long factor developers, and long in short factor developers, the total time error in length of development will be about the same, whether a long or short factor developer is used.

Probably in most cases of difficulty of observing the "time of appearance" it is a blend of two or three of the above causes. Developers with long factors, say 20 or 30, and very short times of appearance, should be avoided. But I do not thing that with an ordinary observer there is greater inaccuracy with a developer of factor twelve than with one of five.

I think that motor and cycle driving have quite altered the quickness of mental decision in this generation. A remedy for not seeing when the image appears is to make the dark-room light copious and efficient. The plate should not be exposed to it all the time, only for a few seconds when observing.—Yours truly,

Hereford, February 6. ALFRED WATKINS.

To the Editors.

Gentlemen,—Mr. Watkins's invitation to practical photographers who are familiar with factorial development to publish factors for different developers and make their knowledge available for others is not meeting with the response that it deserves. I can remember that similar appeals from him in the past have been met with the same silence. A list of factors suitable for use in the development of bromide paper is given below :—

	Factor.
Amidol (Kodak formula), normal strength	12
Amidol (Kodak formula), ½ normal strength	15
Amidol (Kodak formula), ¼ normal strength	18
Amidol (Wellington formula), normal strength	8
M.-Q. (Wellington formula), normal strength	6
Tabloid Rytol, normal strength	6
Azol (1 in 30), normal strength	15

In general, a suitable factor for bromide paper development is from a half to two-thirds of the negative factor given in the Watkins Manual and the "B.J." Almanac. In my opinion the suggestion in the Wellcome Exposure Diary to divide the negative factor by three yields a factor which is too low and leads to under-development. With amidol of the normal strength, Kodak formula, a factor of five is particularly useful as a guide to the development of a bromide print destined for bromoil. This low factor necessitates the requisite amount of over-exposure in the bromide print appropriate to this process in order that sufficient depth may be obtained with the low degree of development.

Mr. Hall points out the possible error in timing the first appearance of the image. It is fallacious, however, to apply the data derived from experience with plates in order to make critical deductions in the case of bromide paper. The accuracy with which the time of the first appearance can be judged depends almost entirely upon the strength of the light under which examination is conducted and the rapidity of the growth of the image. Admittedly, a dark-room illuminated with an orange safe-light suitable for bromide paper is more happily conditioned than one illuminated with a red safe-light suitable for plates, and undoubtedly the image upon a piece of bromide paper grows more rapidly than it does upon a plate whose total development time is five minutes. This rapid growth and good inspection light makes the appearance of the image *a very clearly defined event*, and I am satisfied, as the result of many experiments relating to temperature coefficients, that an error of more than one second need not be feared. Under average conditions (not the 65 deg. F. of the instruction leaflets, which is only normally present in England upon a few days in each year), the time of appearance of the image upon bromide paper is usually about 15 seconds, yielding a total development time of three minutes. An error of 12 seconds in this total time of three minutes can readily be shown to make no appreciable difference to the depth of the finished print.—Yours faithfully,

B. T. J. GLOVER.

THE NORTHERN EXHIBITION.

To the Editors.

Gentlemen,—Now that the exhibition is closed, one may safely raise at least one point in connection with the management at Liverpool, and one which is of vital interest to exhibitors, and to the well-being of the standing of the "Northern" itself. It has been a tradition at this exhibition that the judges only selected the pictures to be hung. This is a safe policy, not only for exhibitors themselves, but as a safeguard to the managers and directors of the exhibition.

This year at Liverpool a self-constituted body of judges of members of the local society took upon themselves the duty of making a first selection of the pictures prior to the judges' work being undertaken. If the judges saw the whole of the prints and marked them afterwards I do not know, but we all realise it is a dangerous proceeding to act in this way if the confidence of the exhibitors is to be maintained. It is reported that many pictures selected by the

local committee had already been hung before the visit of the judges.

Having the above fact in view, I paid a visit to one of the Manchester society delegates, who told me he did not know what had happened at Liverpool, and would not commit himself, but he assured me it was a "landmark," that the selection of pictures be in hands of the judges, and it was usual to submit all prints and slides to the judges first, and who saw them marked A, B, or C. These prints to be disposed of as follows:—

A.—Must be hung.

B.—May be hung if wanted to fill walls or help in scheme of spacing of the prints.

C.—Must not be hung.

I hope with these few remarks to indicate that there is some feeling of dissatisfaction with exhibitors at least on this point. There are others, but to me the one mentioned above is the most vital to exhibitors, and it is hoped any wrong impression will be removed before the next Northern exhibition, which, I understand, is to be held in Manchester.—Yours truly,

NORTHERN EXHIBITOR.

[Several letters received at the time of going to press have had to be held over for appearance next week.—EDS. "B.J."]

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent. International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

G. E.—There is not at present a standard rate or minimum of reproduction fee. Portrait photographers in London have united to charge the minimum fees set forth in the "B.J." of December 24 last, page 790, that is to say a fee of 10s. 6d. for reproductions up to 4 sq. in.; 14s. up to 14 sq. in., and 17s. 6d. up to 30 sq. in. Also some of the large press photographer firms have likewise joined together in enforcing a minimum fee, which we think is 14s. 3d., as against the previous 10s. 6d.

G. S.—Presuming that the negatives have really been thoroughly fixed throughout we should first of all try soaking in a bath made up of chrome alum, ½ oz.; citric acid, 1 oz.; water, 20 ozs., for say 20 minutes. If this does not clear away the greenish stain we doubt whether it can be cleared so as to give a uniform colour of negative, but supposing that the above clearing bath is not sufficient for the purpose, we think the best thing to do would be to pass the negatives through the chromium intensifier, that is bleaching in the usual mixture of bichromate and hydrochloric acid and re-developing with amido[1]

F. T.—The amount of caustic soda required depends not only on the quantity of paramidophenol, but also on that of the potass metabisulphite, since both of these are neutralised by the caustic soda. We think it will probably be near enough for your purpose if we put the relative quantities in round figures as follows:—One part of paramidophenol hydrochloride requires 0.3 parts of caustic soda; one part of potass metabisulphite requires about 0.4 parts of caustic soda. Thus, supposing you use three times the weight of potass metabisulphite relative to the paramidophenol you will require a quantity of caustic soda equal to 1½ times the weight of the paramidophenol.

J. B.—We do not understand what you mean by "copyright number." It is not necessary for the word "copyright" to be marked on a copyright print, and to the best of our recollection, even in the days before the present Act came into force, it was not customary to assign a number to the works registered at Stationers' Hall. We think you can take it as practically certain that any photograph of recent date is copyright. The only question is, to whom does the copyright belong? If it does not belong to your customer, both you and he are equally and separately liable in respect to any action which the owner of the copyright may take on account of its infringement.

T. and R.—The Dallmeyer 3B lens has an intensity of about *f*/3.16, therefore it should require rather more than one-third the exposure of a lens working at *f*/5.8, not ⅛ as you state. You cannot do better than use the 3B, unless the field is not sufficiently flat. In that case one of the new Aldis *f*/3 lens would probably answer your purpose. It would work rather faster than the 3B. A 4.5 lens would only be about half as fast again as the 5.8. With 4,000 cp. and this aperture (*f*/4.5) good negatives can be made on 500 H. and D. plates in about ¾-second. It must be remembered that the distance between sitter and lamps is an important factor. Try placing the sitter nearer the lights.

G. D.—Try a mixture as follows:—Strong gum solution, 1 oz.; crystal caramel, 1 oz.; lamp black (previously ground in the minimum quantity of water), 1-2 ozs.; alcohol, 2 ozs. The crystal caramel is the special make of Litchtenstein, Silvertown, London, E., obtainable from large chemists, such as Johnson's, if you want only a small quantity. About the best method of applying the backing is to put the plate, glass side outwards, in an ordinary printing frame with a soft piece of pure filter paper between the emulsion side and the back. You can then hold the frame with its back to the safelight and apply the backing with the minimum of light-action and without risk of any of the backing getting on the emulsion surface.

R. T.—(1) The only effective means of avoiding reflections from the tablet is to fill the space on both sides between the camera and the tablet with screens of dark material. Professional copyists regularly do this by taking with them large screens of dark cotton stuff, which can be rolled on bamboo rods and extended by strapping these latter to chairs, or getting the help of assistants to hold them in position. It depends, of course, on the available light whether you should use such screens on one or both sides of the tablet. Smearing with oil would no doubt do a little good, but not much. (2) Impossible to say what the lens is. The photograph you mention was not enclosed, but even if we had it we do not think we could identify the lens from it. Some doublet lenses are not rectilinear, but it is unusual to find marked distortion in any doublet lens. Stopping down makes no difference whatever. You are quite right, for general work the R.R. type of lens is the most suitable. (3) In making a block from a photograph it is possible to enlarge just as in ordinary copying, but engravers do not care about doing it as the result is not so good. Still, it can be done up to, say, two diameters.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3172. Vol. LXVIII. FRIDAY, FEBRUARY 18, 1921. Price Fourpence.

Contents.

SUMMARY.

In a further article we deal with early and out-of-print works on special branches of photography which are listed in Messrs. Sotheran's large catalogue, "Bibliotheca Chemico-Mathematica." These include some notable books on studio lighting, photo-micrography, stereoscopic photography and photographic optics. (P. 90.)

Formulæ for a wide range of light-filters, published in the early part of the war by a Herr Hnatek, have become available via a French translation by M. L. P. Clerc. (P. 95.)

A thoroughly characteristic address by Mr. Pirie Macdonald, of New York, on a suggested code of ethics for professional photographers has received somewhat belated publication. It would seem that from the Scottish ancestry which his name suggests, Mr Macdonald derives the stern moral sense of the Shorter Catechism, combined with the worldly wisdom of modern Americanism. (P. 92.)

In a contributed article "Thermit" endeavours to signalise the factors in the making of portrait photographs which chiefly contribute to a life-like presentation of the sitters. (P. 91.)

Heroic methods for securing "life" in canine portraits have recently been mentioned by a correspondent. (P. 90.)

For washing a considerable output of prints there is no better system than the cascade washer which a photographer can readily have made from the description in a paragraph on page 89.

The view of a leading dealer in amateur photographic requisites is that the present scale of charges for dry-plates is accelerating the adoption of roll-film and roll film cameras by amateurs. (P. 89.)

We regret to record the death after a short illness of Mr. John R. Griffin, director of the well-known firm of John J. Griffin and Sons. (P. 97.)

Brief particulars have been published of the settlement of the dispute between the Eastman Kodak Company and United States Government in reference to the anti-trust legislation in that country. (Pp. 90 and 102.)

Lenses of "rusty" appearance which are occasionally found among the surplus instruments now being sold are best left alone rather than subjected to a re-polishing process. (P. 90.)

Hints on the use of the Pointolite arc lamp in enlarging and on routine in the making of enlargements with a lantern are contributed to "Assistants' Notes." (P. 98.)

Details of the production of dye colour images and of anastigmat lenses of *f*/2 aperture are published in recent patent specifications. (P. 98.)

A method of intensifying finger prints with aluminium powder prior to printing therefrom on to a photographic plate or film is described as an important improvement in the technique of criminal investigation. (P. 102.)

EX CATHEDRA.

Cascade Washers. We were recently asked for advice upon the selection of a system of washing prints and enlargements which were coming through all day at irregular intervals. In these circumstances we unhesitatingly recommended what is generally called the cascade method. It is based upon an old idea which has stood the test of time, and it is simple and not wasteful of water—a matter of some importance nowadays. The installation consists of a series of wooden troughs, each large enough to accommodate the biggest prints likely to be dealt with in quantities. These are arranged like a shallow flight of stairs, the water flowing into the uppermost one through a perforated tube at the farther edge. When the first tray has filled, the water overflows through a series of openings into the tray below and from that in the same way through the others. In most cases a convenient arrangement would be four trays, each about 24 x 20 and five inches deep, and if space be limited the trays may slightly overlap. The prints, after a preliminary rinse from the hypo, are placed in the lowest tray, and after five minutes in this are successively placed for the same time in each of the higher ones. If a large number of prints have to be dealt with the number of trays may be increased, so that the longer time will compensate for the crowding in each tray.

* * *

Plate Prices and the Amateur. The continued high level of the prices of dry-plates is the subject of an appeal—or perhaps we should call it a warning—from one who has his finger on the trade in amateur photographic requisites. When it is said that it comes in the shape of a letter from Mr. Oglesby, of Messrs. Sands, Hunter, and is moreover printed in the "Photographic Dealer," and endorsed by the editor of that journal, it cannot be dismissed as mere idle comment. Mr. Oglesby's diagnosis is that the present scale of prices of plates contributes to a movement which has been notable among amateurs during the last few years (in part as the outcome of other circumstances), namely, the choice of roll film and roll-film cameras instead of plates and plate cameras. The position appears to be that the users of roll-film cameras form the large and a growing majority of a dealer's customers, and, further, even though they do no more photography than the making of the exposure, are individually better customers than users of plates. On these grounds only, the dealer's interests lie more and more with film. Discounts, likewise, enter into the question of the sale of the respective materials, and give rise to the wish on the part of dealers that their own interests and those of dry-plate makers could be brought more closely into correspondence. We know Mr. Oglesby to be a shrewd judge of the trade tendencies which his position gives him the occasion to observe, and there seems good reason to confirm his view that the present

conditions are those for transferring amateurs' purchases of sensitive negative-making materials from plates to film in increasing volume.

* * *

The Eastman Kodak Trust. Assuming the correctness of the report telegraphed to the "Times," which we reproduce on another page, the long drawn out action by the United States Government against the Eastman Kodak Co., under the Sherman Anti-Trust Act, has had a very tame ending. The Company has been ordered to separate from itself that part of the undertaking connected with the manufacture of Premo and Century cameras, representing, so it is stated, less than one-twentieth of the capital value. It can be understood that this is the branch grafted on to the parent tree which can be most readily lopped off again, for the manufactures are distinctive products which have experienced little change at the hands of the Eastman owners. It has been different with other businesses, particularly those engaged in the manufacture of sensitive materials. These have been not merely absorbed by the Kodak organism (as Dr. Mees might perhaps express it), but digested to a state defying restoration to their original shape. An example of the saying of Pierpont Morgan that one may as well expect to dissolve a trust as unscramble an egg.

* * *

Rusty Lenses. Just now quite a number of high-class lenses, demobbed from Government service, are finding their way into the hands of photographers, and in some of these which we have handled the glasses are rather badly tarnished or rusted upon the surface. This has little detrimental effect upon their performance, especially with isochromatic plates; the only danger to be apprehended is from attempts to re-polish the surface. Some photographers imagine that friction with rouge or putty powder, the materials used in polishing, may be done with impunity, but there is a great risk of spoiling the definition of the lens by using such means. Moreover, it is as likely as not that the rust will persist in spite of the polishing. We have seen a lens in this condition which had been reground with emery and re-polished by the maker on which the stains were still evident. The best thing to do is to let well alone, and to keep the lenses in a perfectly dry place when not actually in use. The defect is caused by damp and will never occur if any condensation upon the surface is immediately removed. Tightly fitting caps for both ends of a lens are the best safeguards.

* * *

Canine Portraits. Any photographer who has ever had a single specimen, or worse still a group, of the canine species to photograph will admit that neither is to be regarded as an easy proposition, especially in the case of show dogs, where the particular "points" of each animal have to be emphasised in the photograph. Without these being clearly discernible the best technical photograph is worthless in the owner's opinion. Different photographers have each their own methods of attracting the attention of their sitters at the critical moment, with a view to securing good poses and interesting expressions. One worker of our acquaintance has found cat calls highly effective, but we are not all gifted with the necessary vocal ability to make these sufficiently realistic. Some time ago we were told by a dog-loving friend of a method of procedure which displayed not only originality of mind but an infinite capacity for taking pains. He arrived, in this particular instance, with a stuffed cat upon a pole, and he took an assistant with a violin. At the crucial moment the "sitters" were called out, and presumably while they were investigating the presence of the cat, the violin gave a scream that ensured upraised heads and the "alive" expression so desirable in a good dog portrait. That such a method is successful every time we should doubt, but the hint may have its application. The only other items essential are a reflex camera with large-aperture lens, fast plates; plus plenty of patience and a knowledge of dogs and their characteristics

THE EARLIER LITERATURE OF PHOTOGRAPHY.

II.

Returning to the notes on the many out-of-print books on photography contained in Messrs. Sotheran's "Bibliotheca Chemico Mathematica," to which reference was made in our issue of February 4 last, we may make allusion to some of the works dealing chiefly with processes which followed wet collodion, or with particular branches of photographic work. But first we should point out that Messrs. Sotheran's list includes copies of some of the old books relating to the pre-photographic history of the camera. Notable among these is the celebrated "Magiæ Naturalis," of Giovanni Battista della Porta, of 1585, in which is described a camera obscura, but one without a lens. Porta's description of a camera fitted with a lens occurs in a much later and greatly different edition of this work, and though he has often been popularly described as the inventor of the camera, the instrument may be traced to a much earlier date, for example, to the writings of Daniel Barbaro; and Messrs. Sotheran's commentator puts its first description in a work by Levi ben Gerson, translated in 1342 under the title "De Sinibus et Cordis." The student wishing to obtain an idea of the state of knowledge of the camera obscura and other scientific instruments in the seventeenth century may turn to "Collegium Experimentale," by Johann Christoph Sturm, of 1676, a review of the chief scientific discoveries of the time. Works on the camera obscura belonging to the eighteenth century are, of course, plentiful. One of these is that of Georg Friderich Brander, "Kurze Beschreibung einer Neuen Art einer Cameræ Obscurie," a rare work published in Augsburg in 1767.

But turning to the later processes of photography, two early works of Abney on dry-plate emulsions are "Emulsion Processes in Photography," of 1878, the only native treatise on emulsion making, and one which has been out of print for many years, and "The Practical Working of the Gelatine Emulsion Process," of 1880. A notable manual on processes of printing is "Elementary Lessons on Silver Printing," by W. M. Ashman, of 1888. Unfortunately, the valuable contributions which Ashman in collaboration with Offord made to the working out of formulæ for print-out gelatine emulsions occur only in the periodical literature, and chiefly in the shape of the series of papers published in the "Photographic News" of the year 1885. A manual which is still to be purchased fairly freely secondhand—Messrs. Sotheran price it at only 3s.—and is one of the best ever written from the technical standpoint, is "Photographic and Photo-Mechanical Printing," by W. K. Burton, issued by Messrs. Marion in 1887. Although the photographic printing processes, such as albumenised paper, plain salted paper and others, have passed out of use, the volume is a rare storehouse of the expert knowledge of the subject possessed by Professor Burton, and even to-day, as regards the photo-mechanical methods, contains much of value for current instruction. We come to a somewhat later date in two large general treatises, namely, "La Photographie Moderne," by Albert Londe, of 1896, and "Photography: Its History, Processes, Apparatus and

Materials," by A. Brothers, issued as a second and last edition in 1899 by Messrs. Charles Griffin. The latter large treatise occupies a place by itself owing to its size and arrangement. No other book of the time afforded such a comprehensive review of the technics of photography, and it may be thought a pity that Messrs. Griffin have not continued to issue it with revisions in correspondence with current progress.

The chemistry of photography is represented by few works, for writers on this subject have been few in number, and the treatises, by authors both in this country and the continent, have been somewhat fragmentary. But a notable book is "The Chemistry of Light and Photography," by H. W. Vogel, a revised English edition of 1876. Another book containing a vast amount of information on photographic chemicals is "Materia Photographica: the Manufacture, Properties and Uses of the Substances employed in Photography," by Clement J. Leaper, published in 1891. Then there is the volume by Abney, "The Action of Light in Photography," the basis of which is a series of lectures delivered at the Camera Club. It contains an account of the author's sensitometric work, which is not readily obtainable in any other form. A little pamphlet which is deserving of mention is that by the late Dr. W. J. Russell "On the Action of Wood on a Photographic Plate in the Dark," a reprint of the author's paper of 1904, in which the fogging or desensitising action of many materials previously supposed to be inert was systematically examined. And, to take a jump back to the mid years of photography, there is a copy of the large and scarce treatise of Edmond Becquerel, namely, "La Lumière: ses Causes et ses Effets," a large volume describing the author's many observations on phosphorescence and the chemical action of light.

Stereoscopic photography is a branch which has a somewhat scrappy literature. Messrs. Sotheran catalogue an interesting work of which we had not previously heard, namely, "Teneriffe, an Astronomer's Experiment," by C. Piazzi Smyth, published in 1858. It is stated that the score of photo-stereographs in this volume constitute the first application of stereoscopic photography to book illustration. We are quite ready to believe it, for Piazzi Smyth was accustomed to look far ahead towards photographic possibilities, as witness his suggestion many years ago of cameras, which have only lately been realised, in those of the vest-pocket and smaller size. An early manual is "How to Take Stereoscopic Pictures," by William Ackland (1859); two French manuals, both having the same title of "Traité de Photographie Stereoscopique," are by A. L. Donnadieu (1892) and L. Mathet, of about 1899.

What we imagine to be the first manual of photomicrography is "Die Photographie als Hülfsmittel Mikroskopischer Forschung," by J. Gerlach, published in Leipsic in 1863. Other manuals on the same subject are "Photo-Micrography," by A. C. Malley, of 1885; "Lehrbuch der Mikrophotographie," by R. Neuhauss, of 1890, and "Traité Pratique der Photomikrographie," by L. Mathet, of about 1899.

Among these manuals of sections of photographic work we should not omit to mention one or two of the old books on portrait photography, volumes containing a great deal of information for the present-day portraitist; for while methods of negative making and printing may suffer radical changes, the art of lighting a sitter for a pleasing portrait remains essentially the same. These books are "Artistic Lighting," by J. Inglis, of 1897; "The Skylight and Dark Room," by Elbert Anderson, published in Philadelphia in 1872; "The Photographic Studios of Europe," by H. Baden Pritchard, of 1882, and also an early work on retouching, "Concise Instructions in the Art of Retouching," by Burrows and Colton of 1876.

We must conclude these already lengthy notes by reference to the more important volumes on photographic optics which figure in Messrs. Sotheran's list. A manual which for many years was widely read is "Photographic Optics," by Van Monckhoven, of 1867. There are also "Traité Elementaire de l'Objectif Photographique," by E. Wallon, of 1891; "L'Optique Photographique," by P. Moessard, of 1898; "Telephotography," the large treatise by T. R. Dallmeyer, issued in 1899, and "Theorie und Geschichte des Photographischen Objektivs," by Dr. M. von Rohr, the most comprehensive and authoritative work on the history and properties of photographic lenses. And to go back nearly fifty years, there is the rare work of the Abbé Francois Napoleon Marie Moigno, "Repertoire d'Optique Moderne," a large treatise on the history of modern optical theories during the first half of the nineteenth century, and containing a section dealing particularly with the optics of photography.

LIFE IN PORTRAITS.

I HAVE just been looking over a number of portrait photographs by different camera artists in diverse styles and qualities, and I am struck by the fact that only a few of them have a real "live" appearance. In the others, there is nothing to convince the spectator that they are actually from life and not from models or drawings. There are three in particular, which, when placed in a line, show very plainly the point I am concerned with at present. No. 1 is a bust of an obviously theatrical person. The head is certainly a round and solid object, but to know that it was photographed direct from a human being I must depend on logic. An identical result could be got from a wax model. No. 2 is different. A man's head, but certainly not solid. Looked at from some little distance it might have been taken from another photograph or from an engraving, but close inspection leaves one in doubt of either. I happen to know that it is a "direct," but it has neither the brilliance nor texture that always belong in some degree at least to human skin. Of No. 3 I know nothing except the bald statement made by the print itself. But that statement says decisively that the subject was alive—and fully alive—when the picture was taken. It is interesting to note that this photograph does not appear otherwise to be as expensive or "classy" a production as either of the others.

Now what determines this live appearance in a portrait photograph? It is governed by the same factors that rule the production of good work in general, and so is sometimes obtained unconsciously. But it can be made a regular thing by any good worker, and need not be left to our leading camera artists as an exclusive feature.

The first thing is, naturally enough, a live appearance about the sitter, and this goes a long way, but nevertheless is not a *sine qua non*. A live expression on the face is more important. Every operator has—or should have—his methods of getting desired expressions, but for the benefit of those who need a hint I can recommend the following. Having got

everything ready for the exposure we address the sitter, regardless of empty grins or bored looks, something like this. "Now, Sir (or Madam as the case may be), please keep precisely as you are for another moment. You look fine (or beautiful as the case may be)." The sublime expression which invariably dawns has to be seen to be appreciated.

A sitter's complexion also affects the results we are aiming at. There is little or no white in human flesh and skin, which may show red, pink, purple, brown, cream, blue, green and other tints, and on this account colour-sensitive plates are more likely to preserve the living appearance than colour-blind plates can. At the same time excellent results are obtained on plates and films which are not—or are not supposed to be—colour-sensitive. I have mentioned films; which reminds me that halation alone can destroy the live quality of a picture, and therefore a non-halative plate or film should be used.

Exposures should be as nearly exact as possible. Neither under or over exposure will get the best scale of gradation from the latitude of any emulsion, though the last is not so detrimental as the first.

Lighting, for general work, should be full and plentiful without being flat. An expansive and high supply of diffused light with a small point of direct light somewhere near its centre is a rough description of a simple and effective form of lighting. Reflected light must be controlled by very deliberate inspection, and if it can be done without, so much the better.

Great depth of focus and pin-sharp definition all over are not required. Soft focus and a suggestion of fuzziness around outside edges give an impression of movement which is almost essential. At the same time, decided unsharpness is not wanted or of any use. Any lens other than one designed for portrait work should always be used at full aperture to avoid "still life" definition as much as possible.

Provided we can develop intelligently, there is only one point to consider here. If we are not using a non-halative plate or film, quick development in normal developer is calculated to give cleaner high lights than very slow action in a tank of diluted solution. The former will bring up the picture before reaching the halation, the latter will penetrate the emulsion before getting to work properly on the image. The necessary amount of development will depend on the grade of printing paper favoured. If this is soft, a fair amount of contrast must be developed into the negatives; for vigorous papers the development should be somewhat curtailed.

Retouching has a lot to do with the final result, particularly if ordinary plates are used, and here are three points for the retoucher who is not an expert. First, there is usually a high-light within a high-light in nature, or, in other words, high-lights are not even spots or patches, but are composed of gradations. To emphasise this by inserting smaller "higher-lights" in the high-lights of a portrait will help considerably provided it is not overdone. Second, light playing on a person's eyeballs can give the spectator quite a decisive impression of life, and this applies also to portraits. If the whites of the eyes and the points or triangles of reflection in the pupils are inconspicuous in the negative, much can be done by the judicious addition of a little retouching lead. Third, the style of work is a factor. Retouching which prints like wire netting or a layer of dust destroys any impression of life. To use an Irishism, retouching is most useful here when it is absent, but if a negative really requires decisive retouching, the shape and direction of the strokes are important. I have always got the best results by restricting myself to short lines, straight and curved running in the (curved) directions that the grain of the skin seems to take—horizontal on the brow, vertical at the temples, oblique on the cheeks, circular round the chin, and across the hands. I find the nose is best treated with horizontal strokes though the inclination is to work vertically.

Of printing mediums, those of the slow development type are at least as good as any, and of surfaces, matt and semi for small heads, semi or rough for large and "Royal" or "Cream Crayon" for extra large. Warm blacks, warm sepias and prints on cream base are naturally suited to representing skin, though strictly speaking, the effect can be obtained on even the bluest black and white if the negative is very good. I have yet to see a harsh picture that was "alive" though Rembrandts and silhouettes are the easiest styles to produce with life. They can, however—and must—be soft, in spite of their brilliant lighting. I have seen flat pictures that were full of life, but softness without flatness would have improved them.

Colour, like warm tones, will add to the impression, but the colouring must be fundamentally correct. The cream must be there, and the reds and pinks must not be opaque or overdone, while touches of blue in the high-lights and blue and green in the shadows—although this may sound unnatural to those unacquainted with painting—are almost certain to be wanted.

In conclusion, I would like to point out that while it is not possible for everyone to emulate our photographic genii we can all strive to improve the quality of our work, and attention to such details as I have enumerated will greatly help.

THERMIT.

A PHOTOGRAPHER'S CODE OF ETHICS.

WE sometimes hear the opinion expressed that among photographers the sense of a professional standard of ethics is not very highly developed, and certainly many things occur which justify that view. It would seem that the need of wider recognition of an ethical code among photographers is realised as clearly in the United States as here, for at its Congress last year the Photographers' Association of America drew up one and devoted a meeting of a Congress to its discussion. For some reason, neither the code nor the discussion of it was adequately reported at the time, but our little contemporary, "Portrait," the organ of the Ansco Co. in America, has now printed it, and has supplemented it by the highly characteristic speech made by Mr. Pirie MacDonald in reference to it. Mr. MacDonald is an old friend of ours, whom, to our regret, we have not seen for a long time. A most successful business man, he, perhaps, among photographers in the United States is the chief spokesman for that American idealism which many people here find to be so strangely interwoven with American business instincts. Individualist as Mr. MacDonald is in the conception and management of his own business as "photographer of men," we are convinced that he means exactly what he says in his pleas for broader and juster relationships of photographers among themselves. While it is less our habit in this country to treat business relationships in language which suggests in turn Marcus Aurelius, Dr. Samuel Smiles and the late Colonel Roosevelt, nevertheless there undoubtedly is a large body of opinion among photographers which will respond to the arguments which Mr. MacDonald advances for a higher standard of mutual dealing among those following photography as a profession. Inasmuch as a great part of his address would be unintelligible without the "code" to which it refers, we place the latter at the head of his remarks. It runs as follows:—

1. My business standards shall have in them a note of sympathy for our common humanity. My business dealings, ambitions and relations shall always cause me to take into considera-

tion my highest duties as a member of society. In every position in business life, in every responsibility that comes before me, my chief thought shall be to fill that responsibility and discharge that duty, so when I have ended each of them I shall have lifted the level of human ideals and achievements a little higher than I found them.

The practice of photography, both as a science and an art, is worthy of the very best thought and endeavour of those who take it up as a vocation.

2. Having accepted photography as a vocation, the practitioner should, at all times and in all places, esteem it an honour to be able to say, "*I am a professional photographer.*"

3. Our brother photographer's name and reputation should be as sacred to us as our own. The off-hand slur, the unnecessary criticism of his work or methods or manners, the meaning smile or shrug of the shoulder, have no place in the daily life of a professional photographer.

4. The re-photographing of the work of another to achieve a saving of cost for a patron is inconsistent with the best interests of the profession, and is not in accord with the established rights of our brother photographer.

5. The cutting of prices in order to get business away from other photographers without any other legitimate excuse is inconsistent with the dignity of our profession and not in accord with the rights of every man to have a fair and open chance to do business.

6. Advertising in its many forms is essential in these days of commercialism, but the claiming of false or ungained honours, untrue statements of any nature, boastfulness of work better done than others can do, depreciation of the work of other studios, are unworthy of the professional photographer, and its consistent repetition should be severely and publicly condemned.

7. The best interest of the patron should at all times be the first thought of the professional photographer. A studio based on service to the patron and demanding fair pay for real service in following the best tenets and precedents of the profession.

8. It is a privilege to give aid and advice to those whose knowledge is less than our own and who come seeking our help, so that they may progress in the practice of photography. We learn most by giving to others of our own knowledge. By refusing to give of the gifts that have been vouchsafed to us, we impede the progress of the art.

9. True service to our patrons is founded on giving them what they desire at a price which leave a fair profit to ourselves. This is not possible without a knowledge of what it costs to do business, therefore we cannot reasonably be giving true service, unless we know what it costs us to sell, and unless we sell at a price which will give us a return proportionate to our skill and to our expense, so that both our reputation as photographers and our credit as business men may be maintained.

The code of ethics is rather hard to talk about, because it is all so obvious. To the code of ethics we, as honest and conscientious men and women, naturally subscribe, and it seems to me that it is a waste of time to go into it in any great degree of detail.

However, the only way to examine this subject is to do it from a cold-blooded, business man's standpoint, but I don't pretend that it must be treated in an unsentimental way, because I feel that there is no real, deep-seated prosperity in any business that is not founded on sentiment.

In the discussion of a matter like the code of ethics, we recognise the fact that there are two types of people, those who first ask the question, "Does it pay?"—and those who ask the question, "Is it right?" However, the whole code might be easily examined from the point of view of, "Does it pay?"

The first item doesn't need any discussion from the standpoint of, "Does it pay?" Of course, you have got to give the very best endeavour and the very best thought. Who would try to run any kind of a business, say a shoe shop or a printing office, and not give it his best thought? An item like that is really a very nice thing to have as a declaration of ideals. "Does it pay?" Of course it pays! It doesn't pay to do anything else.

The second item in the code, however, is rather different, and it is put this way: "Having accepted the profession of photography as a vocation, the practitioner should at all times and in all places deem it an honour to say, 'I am a professional photographer.'" If you are not proud of your job the people that buy your goods are never going to be proud of the goods after they have bought them. They will buy them on sufferance, and though they take them away with them, anybody can knock them. The only way that you are going to put your goods over so that they will stay "put" is to make goods that you know are good. Be proud of them, and let people know you are proud of them. How much good would it do a shyster lawyer, a man who is chasing ambulances and doing all sorts of nasty tricks, to say, "I belong to an honourable profession"? How much honour would the man get out of his profession? He wouldn't get much!

The honour in this profession is the honour that you give to it. The profession can't honour you. You honour the profession by being the men that you ought to be, and therefore, friends, do your job properly every time, and be proud of it.

The third item: "Our brother photographer's name and reputation should be as sacred as our own."

This is the thought that struck me when I read that from the "Does it pay?" point of view: Did it ever pay to let somebody else know that you are jealous? No! The very minute that you suggest, by your manner or by innuendo, that the man around the corner doesn't make quite as good work as yours, the customer has every reason to believe that you are conscious of the fact that he *does* do good work. The only way that you are going to make your customer sure of the quality of yours is to acknowledge the good things that the man does—freely, generously, fearlessly. Then when they think of you, they are going to realise that you are not only a good workman, but a big, broad-minded man! After all, you are the man. There is nothing in the world that is quite so despicable as a fearful person. When a dog comes along on the other side of the fence with his mouth full of bark, if you run, the dog will jump over the fence at you. It is exactly the same way with people. All you have got to do is to show that you are afraid of the man around the corner, and the public will immediate commence barking about him and telling how good they think he is, because they have got something on you, whereas, if you have no fear of him, you will admit that he is what he is. Admit it, it pays! And folk love fearless men!

This question in the fourth item, of re-photographing other people's work, is a foxy question—what? There are a lot of you perfectly dead sure that whichever way I talk you are not going to agree with me! It is true that it would seem at the outset that there are two distinct answers. But we are talking now from the "pay" point of view. Does it pay? The question is, "Does it pay to show that you lack principle?" Doesn't it pay to show your customer, at the expense of a three or five or even a fifty dollar order, half a dozen times a year, that you have principle, that you recognise that there is "right and wrong"—and you know devilish well what the right is! People trust folk that have principle. The only value there is in this world to me is to be able to look in the eyes of some of you folk and have you signify "Why, hang it, we know you are on the level." Principle! Principle!

I am not going to discuss with you, I am not going to lower you by discussing, the question as to whether it is right or whether it is wrong to copy the work of somebody else who owns a negative from which he can make original prints. His genius was put into that negative. No matter whether it is greater or less than yours, it is his genius, and it belongs to him. If you throw a piece of work down every now and again, if you say, not churlishly, of course, "Go back to the man who made the work originally—he is the man who has the plate, and can make you better things from it than I can, and, secondly, it belongs to him and it doesn't belong to me," when then, when those people want somebody who is trustworthy, they are going to think of the man who threw them down for the sake of principle. When they really want something faithfully and well done, do you suppose they are going to take it to a man who they know is a crook? No! They are going to take it to the man who has backbone enough to throw them down and refuse to take money in order to maintain a principle. Bear in mind I am talking only from one side of the subject, "Does it pay? Does it pay? Does it pay?" That is the only point of view that I am trying to show you.

We have pretty well discussed the right and wrong of this copying business while we have been discussing the question of whether it pays. But did it ever occur to you that one of the ways of finding out whether a thing is right or wrong is, before you take a thing from a man, to say, "Would I do it for him?" In these more or less unpleasant times when the cases are so far apart, if a man were to say to you, "Will you?" most of us would say nothing at all, but grab the man by the coat and walk along with him. But you know, really and truly, in these days when it is so awfully short, it would be very wrong not to say to ourselves, "Well, suppose I only had two of them, would I ask him?" And if you wouldn't ask him, cut it out, friend, you have no right to that drink. Exactly the same thing holds true in the copying of pictures. What right have you to copy the picture of another man if you don't want him to copy yours? If there would be any objection at all on your part to his copying any one of your pictures what moral right have you to copy his? Anything that is not fifty-fifty isn't fair. And it doesn't make any difference what he would do. You are the man—yours is the honour or the shame!

Fifth item, the cutting of prices. Pretty nearly as large a question as the other. The attack is rather different, however, as I see it. In ninety-nine cases out of a hundred the other man is making work that is so good that you realise that your stuff is not worth the money you are asking for it, and you cut your prices. You don't believe that your stuff is as good as the other man's or you wouldn't go down. For if you really and truly believe in it you will buck yourselves up and say, "Darn it, I will fight some other way, because my stuff *is* good." When men have a thing that they know is right they fight for it. They don't lie down—and cutting prices is lying down.

I went through a pretty badly fought-over region in France not so long ago, and I am full of the idea that people fight for the things that they believe to be right, and when they have a suspicion that they are not right they are very apt to welch and lie down.

It is always hard to put the prices up. There are men here that were youngsters with me who realise that there was a time in their lives when to raise the price of work a dollar was a something that gripped your heart and made you frightened. When you have got your price up, why have to take another fright? It is *very* hard to go up—it is very easy to go down. I remember going up a mountain once on the ice and in the snow, that took me three hours to go up, and only three minutes to come down. It cost the seat of our trousers, but it only took three minutes coming down. It is just the same way with the cutting of prices. It will take you three years to go up, and about three minutes to come down. Then you have all that fight on your hands to do over again to get the price up to where you know it ought to be. The man around the corner may be getting the business "because he is cutting prices"! No! He is getting the business because his work and your work can't be told apart, in the eyes of the people that are buying the stuff, and they do see a difference in the price. It is your fault. You have not made it sufficiently apparent to the public that your stuff is the best.

Now, it is true in nine cases out of ten that price-cutting comes because a man is afraid. The answer is not to get all the other men in town to sign a hard and fast contract. No, it is not the other men I am talking about. I am talking about *you;* you are the man who is making the work, you are the man who is to stand before your community as a photographer and a gentleman. And the only way that you are going to do it is to find out as to whether your work is really good enough, and if it is not good enough and you don't know how to make it good enough get out and find somebody that will tell you how to make it good enough—and I know that this whole country is filled with fellows who will be glad to help you. I was a youngster once; they were all almighty good to me when I needed help.

The "right and wrong" of price-cutting. In the first place, it is not sportsmanlike. It is like trying to win a race by offering to pay the judges in order to win, offering to put up coin instead of running like hell! There is nothing sporting about the idea of price-cutting. Just once more let us say it means that you have not got confidence in yourself.

But now here in the sixth item is one of those fool obvious things so wrong that they do not need discussion. Why we should have to have it in a Code of Ethics I swear I don't know. Unclean advertising and making untruthful statements—it pays or it doesn't pay. "Does it pay" to make untruthful statements about anything? Does it pay to be boastful in the statement that you put in a newspaper that another man can disprove?—where the person that reads laughs about it. I will tell you where it doesn't pay. The very minute that you make an untrue statement or claim it gets into your soul and makes you feel like a cootie when you look at yourself in the mirror. That is exactly what it does to you. It brings about a quality of moral decrepitude that leaves its stain. I never swear really except when I remember something I have done that wasn't the square thing to do. It makes me cringe, and a man who gets accustomed to doing crooked things is going to find that after a while his soul gets numb and the d——n thing *won't* cringe.

Here is another article in the Code, the seventh, about the running of your business without regard to the best interest of your patrons. Go on and run your business without figuring the best interests of your customers and find out how soon you will blow out. There will not be enough left of you to bother the undertaker. Unless you give more than they pay for, unless a something comes out of the heart, that can't be bought, you can't win. Why, I have seen people, and so have you, that were so stingy that they hated to give up the twelve photographs even after they got the money for them. I actually did see a man wrap up a dozen of fifteen-dollar photographs in a piece of newspaper so as to save an envelope when he had a lot of envelopes under the counter! But *service* doesn't mean giving away envelopes. Service means giving your heart—giving everything you have *every time!*

The ninth article in the Code that says you ought to have a knowledge of what your photographs cost! Does it pay? Does it pay to know what a thing costs? Sure! There is a funny feeling on the part of some people in our business, and I have often wondered about it. They act as though they were wearing a Christian Endeavour Medal or a D.S.C. because they can tell you about costs. "Why, yes, of course." "Do you always keep books?" "Yes, they always keep the books." Friends, if you don't know what stuff costs, you had a good deal better get out and work for somebody who will keep track of what things cost. You are safer with him

than you are with yourself. One of the price-cutting troubles comes very largely because people don't know what stuff costs. As to the right and wrong of knowing costs, it is unfair to yourself, of course, and if it is unfair to you it probably follows that it is unfair to your customer, if you don't know what things cost. For you might sell them for below what they cost, or you might easily sell them for so much above what they cost that you are not fair to your customer. If I am going to take money away from people in the form of profit, I want to know how much there is, so I will know that I am taking it. I want a diagram of what belongs to me and if I am charging so much more for my professional services than my fair share, more than by any possibility I could be entitled to, and I therefore am a crook, I want to know how much of the money belongs to me and how much goes to the crook that I am.

The worst of not knowing is that it breeds suspicion of everybody that you have in the house. If by chance you are making money you don't quite know where it comes from If you are not making money, then you might think perhaps that some of your help are stealing. Lack of knowledge results in lack of confidence; you can't win.

In article eight is another item that is always attractive to me. It is a great thing to be able to give advice to those whose knowledge is less than your own, and it pays to give aid and advice to other people. In the first place it sets you up with yourself. You have something to give, or they wouldn't come to you! It makes you feel bigger. You feel proud of yourself, and you become more capable because of the fact that you have been recognised as capable, and you acquire confidence. Does it pay? The more a man knows the more he will charge for his work, and the more he charges for his work the more money he gets, and the more money he gets the less temptation there is for him to push you! Nobody but a fool is a thief, if he has any money in his clothes, and the man that is really well off doesn't cut into your business and take away your bread and butter Make the man capable of doing really good things and he might outstrip you and charge more money than you do, and then you have no right to kick!

One of the best points about it is that when a man here and there commences coming around to ask advice on technical matters you wake up and say, "I don't know how to answer him. It is something that I have been doing, yet I don't know how to answer his question." It drives you right down into analysis and you find out the why of the thing in order to be able to tell the man, and it pays, because you have found yourself. You have found something that you know the other man thought that you knew, and that now you really *do* know. But don't get chesty, for some day he is going to ask you a "lallapaloosa," one of those "twisters" that you don't know the answer of, and you will have to get busy!

You must apply this code of ethics to yourself and forget the other man. If you don't, you had better tear it up—it is not any good. Don't work like an Anti-Saloon League on another man, and go around and try to smell whether he is making "near beer" on the kitchen stove. No, if you have any morality to spare, stay home and use it. Stay home and attend to your own business, unless you have something to give and if you have something to give, give it as though you loved to give.

The code of ethics isn't built for the government of the other man. A code of ethics is not the thing whereby you get a man into an association and get his name down on a piece of paper, with your hand over the subject matter, and then give it to him with a glad smile and say, "Here is something that you have signed, and you have got to live up to it." A code of ethics is a guide for you. It is not to protect you from the other man. You don't need protection if you have the kind of stuff in you that belongs to our kind of people. I am talking about our American kind of people. I have been over half the world since I saw you last, and I like our kind. I like our kind, because in America we are the greatest bunch of practical, working, every-day thorough-going idealists that the world possesses.

That is the true basis of a League of Nations, but the first league of nations that we want is a league inside of our own nation of men that are really on the level—the right-thinking, hard-hitting, hard-working sort of folk that love one another.

PIRIE MACDONALD.

LIGHT-FILTER FORMULÆ.

Among the doubtless numerous technical contributions to the Continental journals during the earlier period of the war which have escaped notice is one which we are interested in seeing has been resumed by M. L. P. Clerc, and published in an abridged form in a recent issue of "Le Procédé." It consists chiefly of a series of tables of the dyes and the quantities thereof required in the making of light-filters of a wide range of transmissions. The paper appeared in "Zeitschrift fur wissenschaftliche Photographie" in 1915, and is by A Hnatek. We translate M. Clerc's abridgment, and hope that it is easier to prepare Herr Hnatek's filters than to pronounce his name. The formulæ are given for filters consisting of dyed gelatine coatings on glass, the filter usually consisting of two such gelatine-coated glasses, each containing one (in some cases, a greater number) dye. Filters of this form are uniformly indicated in the tables as (*a*), (*b*), and in some cases as (*c*) where a third separate dye-film is used.

The first column in the table is the number of the filter, the second its region of transmission in Angstrom units. The third column specifies the dyes which are used, and the fourth the weight of dye in grammes per square metre of filter, that is to say, the "dye density," to use the term of von Hubl. The fifth column contains the number of c.c.s. of a stock solution of the dye which are to be added to 7 c.c.s. of a 12 per cent. solution of gelatine in order to provide the quantity of coloured solution for the coating of 100 sq. cm. of filter. The entries in the last column relate to the transmission of the filter in respect to the infra red. The property is unimportant in ordinary or visual work, but enters into consideration in the use of panchromatic plates.

The stock solutions of the dyes are of various strengths. The figures given in column 5 therefore do not bear the same relation throughout to those in column 4 as will be clear from the following particulars of the stock solutions which it is necessary or advisable to make.

2 *per cent. Solutions*

Cocaine, new.
Eosine.
Tartrazine.

1 *per cent. Solutions*

Solid red D.
Bordeaux red
Rose Bengal.
Naphthol yellow.
Filter yellow K
Auramine.
Naphthol green.
Lumiere green.

1 *per cent. Solutions, continued:*

Alkaline blue.
Carmine blue.
Hoffmann violet.

½ *per cent. Solutions:*

Brilliant orange.
Martius yellow.
Brilliant green.
Methyl green.
Methylene blue.
Toluidine blue.
Gentian violet.

¼ *per cent. Solutions:*

Acid green.

Filters transmitting approximately 1,000 *Angstrom* units.

No.	Region of transmission in Angstrom units.	Dyes employed.	Dye density gms. per sq. m.	Dye sol. per 100 sq. cm. ces.	Transmission in infra-red.

		(*a*) Tartrazine ..	2.0	1.0	
		(*b*) Carmine blue ..	2.0	2.0	

Filters Nos. 9, 29 and 32 are very dark, absorbing a considerable proportion of the light in the spectral region which they transmit; those of Nos. 10, 17, 28 and 31 are not quite so dark, but still have notable absorption for rays in the transmitted region. Monochromatic filters may be produced by combining suitably chosen pairs of filters in the list, but such combined filters are in every case of great depth of colour.

M. Clerc observes that in the formulation of the filters the attempt does not appear to have been made to obtain complete absorption of ultra-violet. With this object each of the filters, single or compound, could usefully be combined with one of æsculine, containing 1.5 gm. of this substance per sq. metre.

FORTHCOMING EXHIBITIONS.

February 14 and 19.—Leicester and Leicestershire Photographic Society. Particulars from the Hon Secretary, W. Bailey, Cank Street, Leicester.

February 19 to March 5.—Edinburgh Photographic Society. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

February 19 to March 12.—Scottish Salon, Dundee. Particulars from the Hon. Secretary, James Slater, Rosemount, Camphill Road, Broughty Ferry.

March 16 to 19.—Hackney Photographic Society. Latest date for entries, March 1. Particulars from the Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 13 to 23.—Portsmouth Camera Club. Latest date for entries March 31. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

April 15 to 23.—Professional Photographers' Association, at the Photographic Fair, Horticultural Hall, Westminster, S.W. Hon. Secretary. Marcus Adams, 83, White Knights Road, Earley, Reading.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Latest date for entries, March 17. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Latest date for entries, April 16. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs.

DEATH OF MR. JOHN R. GRIFFIN.

We much regret to record the death on February 9 of Mr. John Ross Griffin, director of Messrs. John J. Griffin and Sons, Ltd., from pneumonia after a very short illness. Mr. Griffin, who had been connected with the business which bears his name for practically the whole of his life, was the grandson of the founder of the firm, John Joseph Griffin. Though, perhaps, owing to his somewhat retiring disposition, he was less well-known in the photographic trade than many other members of it, he had always taken a close and active interest in the management of the business, both the photographic side of it and that connected with the supply of scientific instruments and materials. As the representative of the firm he was a member of the Council of the British Research Association, and on other committees relating to the photographic industry took a deep interest in matters affecting the welfare of the trade as a whole. By those who knew him, Mr. Griffin was greatly esteemed for his sound judgment and pleasant disposition. At the time of his death he was in his fifty eighth year.

The late John Ross Griffin.

A DEVELOPMENT TIME CHART.

The following note sent to us by Mr. W. B. Stokes, of the Forest Products Laboratories of Canada, McGill University, Montreal, may be recommended to the notice of users of time development who require a simple method of ascertaining the time at one temperature when that at another is known. It is, of course, limited in its application to a plate of one particular development speed and to a developer of one particular temperature co-efficient, and is thus comparable in its information with a table in which temperatures and corresponding times of development are set forth side by side, as has been done by manufacturers of both plates and developers for their products. But Mr. Stokes indicates a graphic means of ascertaining working data without arithmetical computation.

Development by time is the only practical method in scientific and technological work where panchromatic plates are used or uniform results are desired. Some plate makers give times for the development of their plates to certain degrees of contrast (specific values of gamma) at three temperatures, but the times necessary for intermediate temperatures must be guessed at. To guess a value which progresses geometrically and inversely to some other value would require the mathematical genius of a Bidder. By using the method about to be described, such a value would be found by inspection without any mental effort.

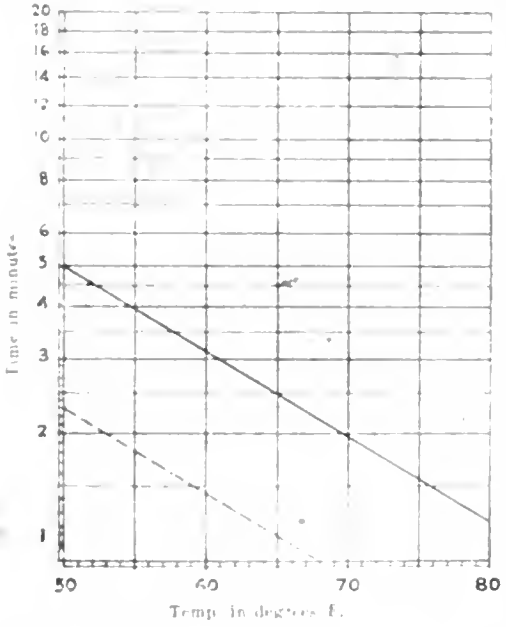
A chart is ruled in co-ordinate fashion so that the abscissæ represent temperatures, and are in equal steps. Any scale will do for this. The ordinates are divided by a logarithmic scale, and represent times of development. A slide rule will provide a series of graduations for the construction of this scale.

The loci of the times of development of a given plate with a given developer at different temperatures lie upon a straight line on such a chart. To draw such a line one needs either two given points or one point and a direction, *i.e.*, either the times for two temperatures or the time for one temperature and the temperature co-efficient. In the example the sloped unbroken line was drawn through two points plotted from the times given for development of certain plates in a certain developer at 50 deg. and 65 deg. F. *The time of development at any other temperature can be found by means of this line.*

Example: The time of development at 60 deg. F. is found by inspection of the line to be about 3.2 minutes and at 70 deg. F. the time would be nearly 2 minutes.

If a greater or smaller degree of contrast be desired the times may be shown by another line above or below the plotted line and parallel to it. If, for instance, by estimation or experiment it is decided that the time of development should be increased one quarter, then a line parallel to the plotted line is made to pass through points corresponding to one and a quarter times the times of development denoted by the plotted line.

That is the advantage of this form of chart. One chart may be used for a variety of plates, degrees of contrast and even different developers. With such a chart the temperature co-efficient is usually only a matter of curiosity, but may be of use when developing other plates, the correct time for one temperature only being known. It is found by drawing a straight line through the intersection of the co-ordinates of 68 deg. and one minute and parallel to the plotted line. This new line cuts the 50 deg. abscissa at a height (2.3) which is the temperature co-efficient, for it indicates the number of times



the time of development is multiplied for a drop in temperature of 18 deg. F. (10 deg. C.).

It is not pretended that the relation between times of development and temperatures is quite as simple as is assumed for the construction of this chart. It is, however, one which has been adopted for practical purposes by such authorities as Watkins, Mees and others, and the establishment of a more exact relation would probably not assist any but the research chemist. The chart, therefore, would appear to be an aid to correct development both as regards exactitude and avoidance of mental effort.

W. B. Stokes.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

The "Pointolite" Lamp in Enlarging.

We have just installed an Ediswan's "Pointolite" lamp in one of our enlarging lanterns, and as it seems to present advantages which are not obtained with any other one lamp, a few notes upon its use may be of advantage to those contemplating a change of light for enlarging.

The lamp is made for use on continuous current, and the one we employ is of 100 c.p. The source of light consists of a small incandescent globule of tungsten about 1/10th of an inch in diameter, and so for all practical purposes is a true point source of light. A special resistance and switchbox are necessary because the arc is struck by first exciting a filament for a few seconds, and then upon opening the exciting switch the arc strikes across to the globule and the lamp goes on them without any attention whatever.

The light is enclosed in a circular bulb very similar to the ordinary small half-watt incandescent filament lamp and can be fixed in a rising and traversing socket for centreing.

Enlarging from a portrait negative on Illingworth bromide paper to a scale of enlargement of two requires an exposure of about a second at *f*/6. With a thin "gaslight" type of negative the exposure to the same scale is simply cap off and on—about half a second. A lantern slide reduced from a half-plate on to an Imperial Special lantern plate necessitates an exposure of a second or two only, so that it can be seen that the lamp is fast enough for anything in the way of enlarging, and with thin negatives enlargements on to gaslight paper can be quite easily made.

And now how does it compare with the arc in use? There are no carbons to adjust and replace, and no spluttering, apparently, ever occurs—the light is as steady as any metallic filament. The spectrum shows a very large proportion of ultra violet, which probably explains its photographic intensity compared with its candle-power. The life of the lamp is given by the makers as between 500 and 1,000 hours, though upon that point I cannot speak. The only thing upon the contra side seems to me to be its cost. The 100 c.p. lamps themselves cost £1 10s., and the switchbox and resistance is priced at £5. The lamp itself consumes 65 watts, to which must be added, of course, that consumed in the resistance, and varying with the voltage of supply, which may be anything from 50 to 250 volts. —Arthur G. Williamson.

Routine in Enlarging.

The best routine when enlarging with a condenser enlarging lantern to various scales of enlargement is as follows:—

1. Insert negative.
2. Rough focus to the size required.
3. Take out negative and obtain an even circle of illumination as described below.
4. Re-insert negative and focus critically to make the exposure.

When two enlargements follow each other to the same scale of enlargement, Nos. 3 and 4 are not necessary, but as soon as a change of scale is made Nos. 1 to 4 must be gone through again.

To carry out No. 3, the following notes will help:—

1. If there is an orange edge to the circle of light the lamp is too far back, so rack lamp forward until a dark patch begins to appear.

2. Dark patch at top indicates the light is too high. Dark patch at bottom shows that the light needs raising. Patch at either side needs the light moving to the opposite side.

To get the most even illumination, stop down the objective somewhat and manipulate the lamp till the disc is even, then open up the aperture as large as possible consistent with obtaining the desired definition.

In the event of the filament of the lamp now being focussed on the easel, a piece of ground glass should be inserted between the lamp and the condenser.—A. G. W.

Photograms of the Year.—The originals of the photographs reproduced in the recently issued volume of "Photograms of the Year," after having been shown at the Northern, are on view at the Camera Club, 17, John Street, Adelphi, London, W.C.2, daily from 11 to 5 until March 12.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, January 31 to February 5.

Camera Attachment.—No. 4,112. Attachment to photographic cameras for production of changing pictures. Move-O-Graphs, Ltd., and A. H. F. Perl.

Changing Pictures.—No. 4,113. Method of producing changing pictures. Move-O-Graphs, Ltd., and A. H. F. Perl.

Photography.—Nos. 3,817 and 3,818. Photography. M. de Sperati.

Flashlight.—No. 4,025. Photographic flash-lamp apparatus. H. Lamplough.

Cinematography.—No. 3,799. Cinematograph apparatus. R. Hodges and T. H. Jones.

Cinematography.—No. 3,798. Cinematographic apparatus. S. S. James.

Cinematography.—No. 3,869. Cinematograph shutters. H. H. and S. H. Moon.

Cinematography.—No. 3,616. Films for use in cinematugraph cameras, etc., lanterns. A. W. Wyatt.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Dye Colour Images.—No. 133,034 (September 20, 1918). The invention relates to the production of coloured photographic pictures, and has for its object to provide a convenient and inexpensive process for the same.

The inventor has found that the finely divided silver in an exposed and developed photographic film has a catalytic effect on the action of reducing agents on certain dyes, which dyes, without this catalyser, can only with difficulty or only at a high temperature be bleached through reducing agents. According to the invention, this circumstance is taken advantage of for producing coloured photographic pictures. In one mode of carrying out the process the picture is developed and the dye bleached in one operation by the same reducing agent.

If, for instance, a gelatino-bromide plate is dyed with the new dye called oxamineechtrosa, manufactured by the Badische Anilin und Soda Fabrik, the plate being either soaked in a solution of this dye or the emulsion coloured before coating, and if such a plate is exposed in a camera, an ordinary black silver picture in a coloured gelatine film is obtained after developing with an ordinary developer and fixing. On subsequent treatment with a powerful reducing agent such as sodium hydrosulphite, stannous chloride, etc., it is found that the dye is bleached in such places of the film on which the silver is deposited, and the degree of bleaching is dependent on the quantity of the silver present, so that a picture with half-tones is obtained. A 1-3 per cent. solution of sodium hydrosulphite may be used. When the bleaching is finished, the silver can be dissolved and removed by known means, such as chromic acid, Farmer's reducer, etc., so that a clear colour picture remains.

Instead of developing the picture with one reducing agent and then bleaching with another reducing agent, the reduction of the silver and the bleaching of the dye can be effected in one operation. The developing and bleaching can, for instance, be effected simultaneously by means of the following solution:—

100 parts of water.
2 parts of sodium hydrosulphite.
2 parts of potassium bromide.

Thereafter the silver as well as the silver bromide can be removed by means of Farmer's reducer.

It should be noted that with some dyes, such as aurophenine,

some ordinary developers, such as amidol, will have a reducing effect when acting for a long time, but for practical purposes a much stronger reducing agent is required, such as hydrosulphite compounds.

These substances have a so great reducing power that a very considerable quantity of a restrainer, such as a bromide, must be used in order to prevent the reduction of the non-exposed parts of the sensitive film.

Instead of oxamineechtrosa, other dyes adapted for the purpose can be used, for instance, the so-called dianilreinblau, aurophenine, congo-reinblau, etc. Most of the dyes adapted for the purpose belong to the so-called dianile dyes. Some dyes, for instance, chicagoblau 6B, give a better result, when the reduced silver, before treatment with the bleaching reducing agent in the known manner, is transformed into another compound, i.e., is toned. The latter dye is thus specially well bleached when the silver picture in the known manner is toned to a prussian blue picture, and when the hydrosulphite solution is made alkaline.

By arranging two or more of the coloured sensitive films on each other or on opposite sides of a celluloid film (which sensitive films may be in a suitable manner sensitised for coloured light and lie directly on each other, or are separated from each other by suitable porous films), it is possible by direct exposure or by printing of a coloured picture, to produce a picture in more colours than one. Thus the method is also adapted for producing colour-prints.

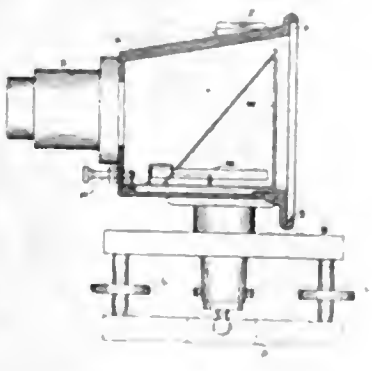
An example of this procedure will now be given:—

If a plate has been coated with a silver bromide emulsion which has been coloured red by oxamineechtrosa, and it is desired to place upon this coating another coating of a differently coloured emulsion, for instance, an emulsion coloured yellow by chrysamine, this cannot be effected without the dyes in the two coatings diffusing somewhat into each other. In order to prevent this, the first coating is coated by a thin porous film of collodion produced by pouring on the first dried coating some collodion containing 2 per cent. of celloidine and 2 per cent. of glycerine. After drying, the second emulsion can be poured on and the collodion film will prevent the dyes from diffusing into each other, but will not prevent the developer from acting upon both emulsions during the development and bleaching.

Some of the dyes used in carrying out the invention colour the gelatine directly and need no mordanting. With others, for instance, chicagoblau, a mordanting is desirable, for instance, by precipitating the dye in the film with metal salts in the known manner.

Chicagoblau can, for instance, be mordanted by soaking the coloured film in a 1 per cent.-containing solution of copper sulphate or in a 2 per cent. containing solution of chrome alum.—Jens Herman Christensen, Villa Sterrehus, Sovejen, Sollerod Holte, Denmark.

PHOTO-SURVEYING CAMERA.—No. 156,956 (November 5, 1919). Angle-measuring devices are dispensed with, the camera consisting of a conical or pyramidical body, fitted with the usual



fiducial means. In the drawing, A represents the body with lens D and plate carrier S. B is the support carried by the levelling screws L, and P is the attachment for tripod. E represents the level bubbles, W is the rectangular frame carrying the four node points, H the handle which moves the frame W on the slide, and M is the transparent vertical circle of the internal compass.—Stephen Mitchell Dixon, 18, Carlyle Mansions, Cheyne Walk, London, S.W. Reference has been directed, in pursuance of Section 7, Sub-section 4, of the Patents and Designs Acts, to Specification No. 14,460 of 1894.

F 2 SIX-LENS ANASTIGMATS.—No. 157,040 (August 14, 1920). The invention relates to an extremely wide aperture lens for photography, cinematography, micrography, and for all purposes for which a lens yielding an extended flat field at a large aperture is required.

It is well-known that the type of lens known as the Gauss lens (fig. 1) is particularly favourable for reducing the so-called spherical zones and is used therefore as a wide aperture telescope objective. Such a type of lens is well adapted for photography by proper choice of glass and of lens curves and thicknesses, whereby the field is flattened consistently with the correction of spherical and chromatic aberration. By the combination of two such lenses (fig. 2) a photographic objective is obtained corrected also for coma and for distortion.

A modification of this type of lens is described in Patent No. 27,635 of 1899, in which either or both of the single meniscus lenses (collective or dispersive) is replaced by a pair of lenses cemented together, of equal or nearly equal refractive index and different dispersions, the object being to achromatise the combination. The complete lens in the example there given had an aperture of *f* 4.

The present invention is an improvement of this type of lens whereby an aperture of *f* 2 is obtained. To attain this aperture great freedom from spherical zones is necessary. Exhaustive research and computation have shown that the desired result can be obtained by the use of dense barium crown glass for the collective components.

The form of present objective is then, two meniscus collective lenses of the dense barium crown glass, the refractive index of which for the D line of the solar spectrum is not less than 1.60 containing between them two meniscus disperative lenses. These disperative lenses are compound, and each consists of a plano, or nearly plano, concave lens of flint glass cemented to a plano, or nearly plano convex lens of the same or similar dense barium crown to that used for the separate collective menisci; where the separating surface is plano or slightly curved in the sense of being slightly collective in effect. It is essential that the components of the compound menisci should differ in refractive

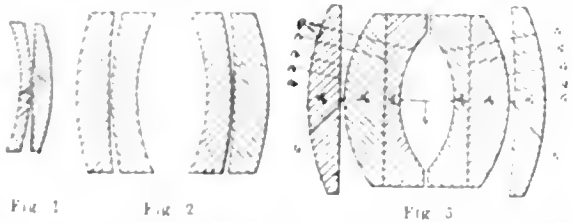


FIG. 1 FIG. 2 FIG. 3

index by an amount of at least .03 for the D line, the disperative lenses having the lower refractive index. The respective dispersions are so chosen as to produce achromatism for the system.

To obtain freedom from coma exact symmetry must be departed from. Calculation shows that the radius of the convex surface of the front compound meniscus, i.e. the one facing the incident light, must be approximately 10 per cent. greater than that of the corresponding surface of the back compound meniscus; also that the back single collective lens must have its shallow surface shallower than that of the front single collective lens, and in fact it is generally flat or only slightly concave.

In Patent No. 27,635 of 1899 mentioned above, use is made of this principle of disymmetry, but different glasses are used, in particular use is not made of dense barium crown glass. In Patent No. 12,329 of 1902, where again a modified type of Gauss lens is described, use is not made of the principle of disymmetry; on the contrary, the correction for coma of one-half

of a symmetrical combination is claimed. Now it is well-known that if two lenses, free from coma, are combined in a symmetrical combination, such a combination will not in general be well corrected for coma, except for unit magnification. To obtain a lens system capable of yielding an aperture of $f/2$ a far higher correction of coma and spherical zone is necessary, which is obtained according to the present invention by the use of dense barium crown glass and the unsymmetric form of the system, as above described.

An example of a lens made according to this invention is shown in fig. 3, of which the following are particulars :—

Equivalent Focal Length 1" Aperture $f/2$ Flat Field 50 Degrees.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, February 15, the president, Dr. G. H. Rodman, in the chair.

An old friend of the Society, and of many of its old members, in the person of Mr. Walter Thomas, delivered a lantern lecture on "Picture Making on the Cornish Coast." Cornwall is old and familiar ground for Mr. Thomas, who, we recollect, was accustomed years ago, when he was chairman of the Affiliation, to find congenial recreation and material for his camera on its picturesque coast. He showed an exceedingly fine series of lantern-slides, and interested a large audience by an informal and matter-of-fact talk on some of the aims and methods of his pictorial work.

On the proposition of the chairman, a most hearty vote of thanks was accorded to him.

CROYDON CAMERA CLUB.

Mr. A. Dordan Pyke paid a return visit last week with an illuminating exposition of "Flashlight Photography," a branch, apart from specialists in the line, hardly relished by photographers in general. Some of the examples of commercial flashlight work, particularly of social functions, such as dinners, are certainly triumphs of technical skill, for inherent difficulties are many. The intensity of the light rapidly diminishes with distance; the orthodox black and white costume of the masculine element could hardly be bettered for the worse; depth of field and rapidity contend vigorously, tempting, or necessitating, the use of a short focus anastigmat, which renders faces at the margins in correct plane perspective with no hope of repeat orders from their owners.

Mr. Pyke's demonstration, intended primarily for the beginner, was complete and practical, and carried through in first-class fashion. It was, however, approached with circumspection and considerable preamble, much in the same way as a fox terrier prior to actual business genially converses about the weather when perambulating around a watchful cat sitting in the open. He spoke sadly of the loss of many friends since he had taken up portraiture; of the peculiarities of various photographic societies, the Croydon Club being the only one with a half-time interval devoted to a specific purpose; of the merits of Ross' lenses; of other things too numerous to mention; and concluded the overture with a dissertation on astronomy. From what he said it is a duty to warn photographers that if they elongate their arms and fool about with the sun's *photosphere* it will take millions and millions of years before they realise they have lost a hand, and then it will be too late. The whole solar system, he added, is advancing at prodigious rate towards the constellation of Hercules. This sounds a bit uncomfortable, but as an important part of the solar system consists of the Croydon Club, some consolation can be derived from the reflection that dear old Hercules may be feeling more so, if he be aware of this fact.

The philanthropic demonstrator having seen to the higher education of his audience, and thus paved a way to a better understanding of what was to follow, then grappled with his subject, and with a measure of success adhered to it for the rest of the evening. A flashlight group of members was taken and a portrait of Mr. Sellors. Both negatives appeared quite good, every detail, including the tobacco smoke, being faithfully recorded. Naturally, Messrs. Johnson and Sons' powder was used, of which there are two sorts, the "ordinary" (for want of a better word) and the "professional." For amateurs the former is, perhaps, to be preferred, as being of more robust constitution; the latter gives a slightly more actinic light, but when mixed will not keep more than a day or two. The other, when mixed, keeps for months. An ingenious pistol-form igniter, supplied by his firm, was employed, and surprisingly little smoke resulted from the two exposures made. Messrs. Johnson issue a very handy table indicating correct exposures for varying subjects, with plates ranging from 200 to 500 H. and D.

In the discussion, Mr. Wadham alluded to a "dust-up with the missus" the morning after a flashlight night before in the drawing room. Mr. Rose wished to know the correct amount of powder for pinhole photography, and drew a blank. Mr. Hibbert had found Johnsons' powder excellent. The "office boy" pointed out that after combustion sufficient of the dust in the air should act as a gentle laxative. In reference to an uninflammable diffuser, Mr. Jobling suggested fine wire netting with interstices filled with aeroplane dope, which, he said, is on the market, though he did not know who supplies it. It costs about one shilling a yard, is flexible, and diffuses slightly less than ground-glass. A most hearty vote of thanks was accorded to the versatile demonstrator for a capital evening. The room was uncomfortably crowded.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held at 116, Hanover Street, on February 7. Present: Miss Bertram, Messrs. J. B. Johnston, J. Campbell Harper, E. D. Young, Norman Thomson, George Balmain, Fergusson, Swan Watson, Bambrick, and Melrose. Mr E. D. Young in the chair.

The chairman thanked Mr. Fergusson for the diffusing screen which he had given on loan to the lighting and posing class at the College of Art. He also thanked Mr. Ayton for his packet of films, and asked if any members could supply any cabinet or whole-plate heads; it would be of great service to the retouching class.

The question as to what arrangements should be made for the holiday season, 1921, was thereafter discussed, and several members expressed the great advantage which had been gained, both personally and professionally, from the adoption of this scheme. Mr. Bambrick asked his name to be added to those who had already agreed to close on the second fortnight in August. It was resolved to continue the matter until next meeting to give any other members an opportunity of joining the scheme.

The meeting thereafter discussed at considerable length the question of the enlargement prices of portraits. No finding was come to, and it was resolved to discuss the matter further at an informal meeting to be held next week. The meeting was, however, unanimous on the point that where the negative was given up the photographers should certainly make a higher charge.

The meeting next considered the proposal, which was supported by Mr Fergusson, that the Society should approach the Water Trustees and get the water rates payable by photographers put on an equitable basis. Mr. Fergusson pointed out that the majority of photographers in Edinburgh, owing to the position of their premises, could not put in a water meter, and that in these circumstances they were charged a special water-rate according to their rental over and above the water-rate paid thereon. Other photographers, whose premises were self-contained had had water meters placed therein, and their water bill was considerably more in amount than the other photographers. The Society, after considering the matter carefully, decided that it was not a question which they as a Society, could take up, but would leave it to the members affected to negotiate with the Water Trustees themselves.

It was agreed to hold an informal meeting of the Society at the Victory Café, on Tuesday, February 15, at 8 p.m., when the question of the enlargement prices of portraits would be fully and further discussed.

Mr Norman Thomson proposed that the Society should offer their congratulations to Mr. Swan Watson on his being nominated as President elect of the Professional Photographers' Association, London. The chairman associated himself with Mr. Thomson's proposal, which was unanimously agreed to, and the meeting conveyed to Mr Swan Watson their heartiest congratulations and good wishes. Mr Swan Watson, in returning thanks, said that the honour had been unsought by him, but he would do his utmost worthily to maintain the honour and prestige of that Association. It was remarked that this is the second occasion on which an Edinburgh photographer had been chosen to act as President of this Association the late Mr Frank P. Moffat having also attained that honour.

A vote of thanks to the chairman concluded the meeting.

Commercial & Legal Intelligence.

LEGAL NOTICES.—A first and final dividend of 3s. 10d. in the £ has been declared in the case of the Excelsior Photographic Company, Ltd., 49, King Street, Carmarthen. The dividend is obtainable at the Official Receiver's office, 4, Queen Street, Carmarthen.

EASTMAN KODAK COMPANY.—The usual quarterly dividends of 1½ per cent upon the outstanding preferred stock and of 2½ per cent upon the outstanding common stock will be paid on April 1 to stockholders of record at the close of business on February 28.

NEW COMPANIES.

H. G. MOURIN, LTD.—This private company was registered on February 5, with a capital of £5,000 in £1 shares (3,000 prof.). Objects: To carry on the business of opticians, ophthalmic and scientific instrument manufacturers, glass manufacturers and workers, camera and photographic dealers and manufacturers, etc. The first directors are: H. G. Mourin, 23, St. Mary Street, Weymouth, optician; F. Mourin, 29, Rue Mont Kemmel, Ostend, Belgium, optician (managing director), with £500 per annum and a percentage of the profits as remuneration. Registered office: 23, St. Mary Street, Weymouth.

News and Notes.

EMBOSSED SEALS AND LABELS.—Mr. F. G. Clarkson, 88, Charminster Road, Bournemouth, sends us a large variety of the gummed and coloured embossed seals and labels supplied by him for attachment to photographer's mounts, folders and stationery. These imitation seals are of effective design, and may be obtained with any brief wording, and in any shape, size, or colour. Application to Mr. Clarkson will bring a small sample packet of various styles and particulars of prices.

BRITISH LENSES. Dealers who have not already obtained a supply from their wholesalers should see that they have for distribution copies of an 8-page booklet entitled "The Photographic Lens," which contains authoritative opinions from expert and official sources on the superiority of the British-made photographic objective. It is shown that the British optician produces lenses of as high a quality, if not higher, than any made on the Continent, and, moreover, has not now to go to the Continent for his glass.

PHOTO-RECORDS OF FINGER PRINTS.—What has been described as the greatest step forward in the science of criminal identification in recent years is the new process discovered by Detective-Sergeant Fred. G. Sandberg, of the Washington Police Force, writes the "Scientific American." This process makes it possible to make finger prints from transparent objects without the use of a camera and lens. It consists of covering the finger prints with aluminium powder and then making a direct contact print on to a piece of sensitised film or photographic paper. This method has been adopted by the International Association for Identification, which numbers among its members some of the foremost finger-print experts in the world.

PHOTOGRAPHY AT THE LOUVRE.—Official regulations for the taking of photographs at the Louvre Museum and Galleries in Paris have recently been issued by the French Government. From January 1 last a photographic studio and several dark-rooms are placed under the management of a custodian, who is responsible for supervision of the removal of works from the galleries to the studio for photographic purposes, and in other ways is authorised to assist photographers in the copying of the many unique works of art contained in the museum. A maximum fee of 12 francs is charged per work photographed, 10 francs being the charge for permission to photograph and for use of the studio, and 2 francs for the cost of removal from the gallery.

MR. D. CHARLES, photographer to Marconi's Wireless Telegraph Co., Ltd., has some hints on the photographing of such difficult subjects as wireless apparatus, in the current issue of the "Wireless World." Remarking that lighting is of paramount importance, he writes :—"It is useless to stand beside the camera in order to judge of the lighting, or to observe whether surrounding objects are likely to show in the result, and the image on the ground-glass is often hardly brilliant enough to recognise easily all these things. The proper method is, first of all, to get the camera roughly focussed and then to remove the lens and open the focussing-screen, so that one can look right through the camera at the objects to be photographed. A little study will then discover any objectionable details in the lighting. It comes as a surprise sometimes how objects in all sorts of positions will be reflected in polished parts."

EASTMAN KODAK COMPANY.—According to the New York correspondent of the "Times" the Eastman Kodak Company of New Jersey withdrew its appeal to the United States Supreme Court on January 31, from the conviction entered by the District Court at Buffalo in 1915 under the Anti-Trust Act. On the motion of the Company's counsel Chief Justice White issued a mandate ordering the Company to abrogate its alleged illegal monopoly in photographic supplies. In consequence of the withdrawal of the appeal, Judge Hazel at Buffalo has entered a decree directing the dissolution of the Company by the sale and disposal of its Premo and Century plates and certain lines of photographic supplies. The settlement with the Government results in no substantial disruption of organisation, as the company is only required to dispose of about $4,000,000 (approximately £1,000,000) of its assets, which total $90,000,000 (£22,500,000).

WARMING A STUDIO.

To the Editors.

Gentlemen,—I have read with some interest the spirited controversy regarding the most efficient method of warming an average photographic studio, and I quite agree with "Comfort" in his contention that a Ventiheta consuming five cubic feet of gas per hour will not maintain the required temperature of a studio measuring 33 × 21 feet, but I do contend that two Ventihetas, consuming on an average 12 cubic feet of gas per hour, would give an agreeable warmth, plus a healthy and hygienic atmosphere in a studio of the dimensions named.

One fact is taken into consideration, that an ordinary gas fire with eight burners consumes anywhere from 35 to 40 cubic feet of gas per hour, and at the same time consumes to a large extent the oxygen of that studio, rendering it dry and unhealthy to work in, therefore the claims of Mr. F. E. Jones and the Ventiheta are well worth the closest examination.

Some 18 months ago I purchased a residence in the Thames Valley, and in a large reception room which was used as a dancing studio, and is 30 × 16 × 12 feet, with four large French windows facing on to a lawn leading down to the River Thames, one Ventiheta, consuming eight to nine cubic feet of gas per hour, effectively warmed and ventilated this studio in a manner which was not possible by any other means, and at a cost hardly conceivable until actually experienced.

Consequently, I consider the claims of Mr. Jones regarding the Ventiheta are thoroughly justified, as I have personally had experience of two winters in the studio referred to herein, and that the Ventiheta is well worth the very serious consideration of photographic artists as a modern and up-to-date method of giving the necessary warmth and comfort to the sitter.—Yours, faithfully,

HYGIENE.

February 8, 1921.

STORING SENSITIVE MATERIALS IN DAMP PLACES.

To the Editors.

Gentlemen,—I have read with the greatest interest your editorial note (page 74) on damp sensitive materials, and although agreeing with you as to the usefulness of calcium chloride as a damp-absorber, I think photographers might with advantage employ oatmeal for the work. Some years ago I was employed in one of the dampest studios within reach of the Seine floods, and my chief made it a rule to keep either oatmeal or sawdust—preferably the former—in the drawers in which our sensitive plates and papers were stored, and by so doing we never had damp materials to complain about. All the oatmeal was taken out of the drawers each week and dried, either in the sun or in an oven; the sensitive materials not being replaced therein until the oatmeal arrived at the normal temperature. Blotting paper is also very good, especially for packets of paper.

Experiments have proved that oatmeal dried at a fairly high temperature, and exposed in a damp place, will absorb 9 per cent. of its original weight in a week, whereas calcium will take up as much as 29 per cent. The simplicity of the oatmeal treatment, however, has much to recommend it. The common cardboard used for making plate-boxes and for stiffening packets of sensitive paper is a great absorber of damp, and I remember some experiments being made which showed that three half-plate pieces of such cardboard would absorb one-tenth of a grain of water in an hour, even when wrapped round with waxed paper, the ends only of the cardboard sheets being exposed to the atmosphere. The matter was, I believe, fully dealt with at the Croydon Camera Club about seven years ago, but I have no record of the lecture. However, those

who wish to keep their sensitive materials perfectly dry and in a good condition cannot do better than give oatmeal a trial, it being, in my humble opinion, an ideal and fairly cheap damp absorber, and one that will last for a generation if properly dried occasionally.—Yours faithfully,

L. T. W.

THE NORTHERN EXHIBITION.

To the Editors.

Gentlemen,—The criticism of the Northern Exhibition in the "B. J." of February 11, although anonymous, appears to have been written in a fair manner.

There are facts, however, unknown to the critic which materially alter the case.

Briefly, these facts are as follows:—

1. The Liverpool Corporation were obliged to reduce from three weeks to two weeks the time during which the Art Gallery was available prior to the opening of the Exhibition. During this period entries which ran into thousands had to be unpacked, recorded, classified, selected, judged for awards, hung and catalogued.

2. In order to save time, and by arrangement with the judges, a preliminary classification was undertaken by an executive committee—not self-constituted, but elected by the L.A.P.A. Council. It was a condition of this preliminary selection that the judges should have all the exhibits submitted to them and that they should have the right to withdraw or substitute any exhibit that they thought fit.

Every rejected print was seen by the judges.—Yours faithfully,

JOHN MACSYMON,
Chairman Executive Committee.

L.A.P.A., 9, Eberle Street, Liverpool. February 14.

AMALGAMATED PHOTOGRAPHIC MANUFACTURERS, LTD.

To the Editors.

Gentlemen,—We have received a prospectus to-day from the Amalgamated Photographic Manufacturers, Ltd., inviting subscriptions. We note that two directors of the company are to receive each per year £2,250, and to a few others payment will be made at slightly smaller rates per year. We ask professional photographers where is it that the A.P.M., Ltd., expect to get profits to be able to pay men at the rate of £41 per week? There is only one answer, and that is, out of ourselves alone.—Yours faithfully,

19, The Terrace, Penzance. LAWLEY BROS.

FACTORIAL DEVELOPMENT.

To the Editors.

Gentlemen,—Dr. Glover has earned the gratitude of many readers by giving so full a table of factors for various developers for developing bromide prints.

Might I appeal to Mr. A. G. Willis, whose excellent article upon making trials in development appears in your last issue, to favour your readers in the same way with the factors he finds right, also stating developer or developers? It will be noted that he says, "I use the factorial method for all studio work (having various factors for the different types of lighting) and find it ideal."

In further reference to Mr. Hall's difficulty, I overlooked some very exhaustive investigations made by Mr. A. Lockett, whose conclusions are given on page 464, "B.J." for 1906. Mr. Lockett made trials with five persons (three of them novices), observing the "time of appearance." His conclusions (in brief) were that the personal element in observation is of comparatively small importance; that a liberal supply of light in the dark-room is the most important item; that there is practically no greater fear of variable results with a large developing factor than with a small one.—Yours truly,

ALFRED WATKINS.

Hereford, February 12.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent. International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. E.—Messrs. Billcliff's address is Richmond Street, Boundary Lane, Manchester.

D. J.—We suggest that you select from the names of the old artists, such as Vandyke, Rembrandt, Rubens, Velasquez, Raphael, Romney, or Reynolds.

C. R.—(1) We expect it was a collodion print which cannot be glossed in this way. (2) Impossible to say what will remove the dirty marks. Probably there is nothing better for the purpose than rubbing with a very soft rubber or with bread crumbs.

E. C.—Probably the Wray lens has a present value of about £1 to a direct purchaser. Some of the Wray single lenses had a somewhat larger aperture of *f*/8. If the lens is of this type its value is about 30s. The Ross doublet is worth, say, from £2 10s. to £3.

G. W.—The Goerz "Hypar" was brought out not very long before the war. The 300 mm. lens is that of 12 inches focal length, of aperture *f*/3.5, and listed to cover a 6 x 4 or cabinet plate. The catalogue price in the latest list we have, one of 1914, is £27 10s.

A. S.—You cannot buy ammonia nitrate of silver, because it is not obtainable in the solid state. It has to be prepared in solution by adding ammonia in small doses to a solution of silver nitrate until the deposit of silver oxide, which is produced by the first additions of ammonia, redissolves, giving a clear solution, as you make further cautious addition of ammonia.

J. W.—In the case of some papers considerable benefit as regards tone is obtained by giving a short preliminary immersion in the sulphide darkening solution, then washing for a short time and then carrying out the ordinary bleach and sulphide process. In the absence of any indication of the kind of improvement you are seeking to make, this is perhaps the best hint we can give you.

C. and E.—The lighting of the groups is fairly satisfactory and the arrangement of blinds is good. A large white reflector (a white background would do) would help to equalise the light on the shadow side. The principal fault seems to be under-exposure. Give at least twice what you now give. We assume that you use the most rapid plates; if you do not, a change of plate may give the desired effect.

T. M.—So far as we can judge, there is no possible objection to your making and selling the attachment for use with a T.P. shutter. There are hosts of instances of the same kind of thing, both in photography and in other trades, for example, fitments for the Ford car. The only question is whether your attachment is an infringement of anybody's patent, but from what we can see that is not likely to be the case.

G. G.—A great many patents are taken out in the course of a month for cinematograph shutters, and most of them claim to reduce flicker. Unless you can ascertain the name of the patentee, or the number of the specification, we do not think you can obtain a copy of the latter. Any specification which is published is obtainable from 25, Southampton Buildings, London, W.C.1, price 1s., but you require to give the number.

M. E.—You are quite right, and have written a very good letter. Presuming that your invoices were in the proper form, that is to say, made it clear that you were charging for the supply of prints from negatives taken, the people have not the slightest ground for now obtaining the negatives. If there is any single thing in the law relating to photographers' dealings with their

customers which is clear, it is the photographer's right to the custody of the negative.

N. E.—(1) Quite reliable in changing. (2) There is a certain liability to static electric markings due to the friction of the films on each other, but in a moist climate like this they are comparatively rare. Certainly not a material objection to the use of the films. (3) We usually develop films like prints in a dish, after having rounded off the corners by snipping them with a curved pair of scissors, but the Kodak Company also supply tanks in which the films are held loop fashion and are very conveniently developed in quantities of a dozen or so.

G. H.—The better lens would be the 7½ inch, provided it covers the plate well to the edges, which probably it will if stopped down to *f*/16. But if there is plenty of space there would be no harm in using the 10½ inch also at *f*/16, and the covering power would probably be better. We should think you would want at least ¼ oz. of powder. You can fire it by laying a small fragment of gun-cotton (from the pharmaceutical chemist) about midway in the train, or you can obtain touch paper from Messrs. Johnsons, 23, Cross Street, Finsbury, London, E.C.2.

E. B.—(1) The aperture is probably somewhere in the neighbourhood of *f*/5.6, if the focal length and diameter of the diaphragm are as you state. It may be a little faster, but would not conceivably be as fast as, say, *f*/5. We say this on the supposition that when you focussed you focussed upon a very distant object. (2) There is no material difference as regards depth of focus between an anastigmat and a portrait lens of the same focal length and aperture. If the subjects are portraits in the studio, the advantage is probably with the portrait lens owing to its curvature of field.

F. E.—When using a large aperture lens, and particularly if there is a substantial distance, say anything above ¼ in. between the blind and the plate, there is both theoretically and practically a decided advantage, as regards efficiency of the exposure, in obtaining a given speed by a wide slit at a higher speed instead of a narrower slit at a lower. The theoretical reasons for this practice have been dealt with in a number of articles, among the most recent of which in our pages is that in the "B.J." of March 14, 1919, which we expect our publishers can still supply, price 5d.

G. M.—(1) We suppose you mean the formula containing mercuric chloride, potass iodide and sodium sulphite. If that is so probably the cause of the yellow deposit, which we expect is mercuric iodide, is insufficiency of sulphite. Your sulphite may be below strength, and therefore more of it required. You may be able to get the deposit to dissolve again by adding further sulphite and shaking, but that is rather doubtful. (2) The print is by rotary photogravure. Quite as good work as the specimen is done in this country, for example, by Messrs. Vandyk Printers, Ltd., Bristol.

H. M.—There are unfortunately no standards of prices for this class of work. For making a whole-plate negative and supplying one print therefrom many photographers at the present time would charge from 15s. to 25s., with perhaps a reduction in the case of a number of negatives taken at the same time, and in some cases plus out-of-pocket expenses. But we think you ought to be able to work out a satisfactory cost on the lines indicated in the article published in the "B.J." of January 21 last, page 30, particularly as regards including a due proportion of cost in respect to your own time and your overhead expenses.

W. G. G.—Ordinary calico or canvas with a coat of white distemper is about the best material for such a reflector as you require. A reflector is not needed above the head, a better arrangement being a sloping diffuser of thin paper or muslin, one edge of which is fastened to the window sash and the other to the ceiling. This gives a certain effect of top lighting. You cannot get over the retouching marks in enlarging except by using a soft focus lens in the enlarger or putting the image very slightly out of focus. It is a common practice to clean off the retouching before enlarging. You can easily do 20 x 16 or larger with an incandescent light unless your negatives are very dense or yellow.

W. D.—We do not know your burnisher by the name given, but it is probably of the ordinary type, a rough roller on top and a polished one below. To use it you must heat the polished roller until it is hot enough to fizzle when touched with a wet finger. The print must be prepared by rubbing with a weak solution of castile soap in methylated spirit, using a bit of clean flannel. You must not use too much soap solution, or the print will have a smoky appearance. Put on plenty of pressure, and pass the prints through three or four times. The prints should be mounted with a wet mountant, as the shellac would probably squeeze out if dry-mounted. This style of burnishing is quite out of date now. A squeeged print dry-mounted will have a much better surface.

J. T.—We find it difficult to discover any explanation of the foggy results from the particulars you give or from the negatives. Both of the latter evidently suffer from chemical fog, due either to bad emulsion or faulty developer. It seems unlikely that a plate of such slow speed could be fogged, and therefore it may be worth while to consider whether the developer is the cause. We think hydroquinone-caustic is, on the whole, the best developer for this type of plate, and the only suggestion we can make is that perhaps the solution may have been wrongly made up as the result of using too much caustic, or from excess of sulphite, or from faulty sulphite. Hydroquinone is somewhat sensitive to sulphite, and too much of the latter will give fog of the kind shown in the negatives.

N. E.—It is a somewhat complicated business, and our first suggestion is to refer you to the article in the "B.J." of January 21 last, page 30, in which we endeavoured to deal, as far as possible in a way to meet individual cases, with the methods of ascertaining the price to charge for such jobs. We think that if you followed the indications there given, particularly as regards the inclusion of charges for your own time and for your overhead expenses in due proportion, you would be able to arrive at a charge which would give you a reasonable profit. There is unfortunately no standard of charges for work of this kind. For taking a whole-plate negative and supplying one print therefrom many photographers would charge from 15s. to 25s. at the present time. Further prints from these negatives, say at Raines's catalogue prices. But unless you have made special contracts to the contrary it is perfectly clear that the negatives remain your property. If you now wish to make a charge for delivery of the negatives to your customers we think you may take it as a fairly reasonable standard that the charge would be about £1 1s. per negative. From what you say, it is evident that you have gone to an enormous lot of trouble to do this work, and if you render your account and cannot obtain payment we should think you would not have any difficulty in recovering the amount in the County Court.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3173. Vol. LXVIII. FRIDAY, FEBRUARY 25, 1921. Price Fourpence.

Contents.

SUMMARY.

In a contributed article Mr. P. M. Jones advocates a particular M.Q. formula made up with caustic alkali as a developer which is economical and convenient in use. (P. 107.)

The æsthetic, technical and business aspects of mounting portrait photographs are dealt with in a series of notes by Thermit. (P. 106.)

M. Louis Lumière, in a recent paper before the French Academy of Sciences, has set forth the theory of a process for the photographic representation of solid objects in apparent relief. The process consists in making several positive transparencies which are mounted one behind another and illuminated by transmitted light. (P. 110.)

In a contributed article Mr. H. J. Comley makes a strong plea for more general use of panchromatic plates, in portraiture as well as for photographing furniture, etc., and gives a number of practical hints on their manipulation. (P. 112.)

At the Royal Photographic Society on Tuesday evening last, Mr. D. Charles read a paper, accompanied by demonstrations, of flashlight photography, more particularly in reference to methods of firing the powder and of shaping the flash by appropriate form of the flash pan. (P. 116.)

A Rochester paper adds to the particulars published last week of the judgment in the Baltimore U.S. Federal Court in the action between the Eastman Kodak Company and the United States Government. It is further stated that the parts of the Company concerned in the manufacture of Artura paper and Seed, Stanley and Standard plates are to be separated. (P. 119.)

According to the "Times," progress has been made in the production of a map of London prepared from aerial photographs. (P. 114.)

A recent patent specification describes a more inexpensive construction of the Cooke lens. (P. 115.)

As a supplement to the ordinary field camera an instrument of quarter-plate or 3¼ x 2½ size serves such useful purposes as providing the means of making a duplicate exposure or of undertaking speculative work at a much lower cost. (P. 105.)

A recent query relating to negatives which had been sold by auction prompts us to refer to the very doubtful provision made in the 1911 Copyright Act for the transference of copyright when a negative is sold without written assignment of the reproduction rights in it to one party or the other. (P. 105.)

The usefulness of a vertical stand for the copying camera is experienced in obtaining any background in conjunction with a shadowless lighting. (P. 106.)

The permulphate reducer is at times a useful corrective of negatives taken of a sitter posed against a brightly lighted window. (P. 106.)

Some hints on the trimming of prints to be made with white margins are contained in a paragraph on page 106.

EX CATHEDRA.

The Mood of the Sitter.

Addressing a meeting of photographers, a few months ago, Mr. Pirie MacDonald made a point which is worthy of the consideration of all serious portraitists. He said it was his practice to ascertain for what purpose the portrait was required, and he then endeavoured to depict his sitter in such a way as would produce the desired effect upon the beholder. For example, if the portrait was to be reproduced in a trade or other newspaper, he would aim at a pose and expression which would convey the idea of intellect, energy and, perhaps, a little sternness, while a portrait intended for a fiancée or near relative would receive a softer treatment. We are afraid that the possibility of working on these lines has been overlooked by most photographers, who are content to produce a good average result without reference to its ultimate fate. It should, however, be obvious that the representation of the chairman of a great company as he appears at a public meeting, while suitable for press work, would not be so acceptable to his family as one showing him in a moment of relaxation when the business man gives place to the husband and father. It is worth remembering that Mr. MacDonald makes the portraits of men only.

* * *

Sale of Negatives and Copyright.

Under the Copyright Act of 1862 it was made clear (in Section 1.) that in the case of the transference of a negative the copyright was altogether destroyed, unless there was a written assignment transferring it to the purchaser. This is one of the important points in respect to which the 1911 Act is different: apparently, according to the present Act, nothing can cause the destruction of the copyright except the natural lapse of the time for which the copyright lasts. Apparently also, under the present Act, if a negative is sold without written assignment of the copyright to the purchaser, the copyright does not go with it, but remains in the possession of the vendor. So far as we are aware there has been no judgment in the Courts, since the coming into force of the present Act, which throws light upon this somewhat dark place of photographic copyright. The general intention of the present Act is that copyright in works of fine art, paintings, sculpture, etc., should not pass on sale of the work without special assignment, and it seems probable that the difficulties that must necessarily occur in applying the same principle to photographic negatives, engraved or etched plates, and similar originals have been overlooked. Obviously, the interests of photographers' customers are those which are chiefly involved in this question, but cases sometimes arise in which, for example, negatives are sold by auction, whilst prints from them remain in the possession of their maker by whom the copyrights were previously owned. In the absence of a judicial ruling the present position appears to be that although the original owner has parted with the negatives

he retains the rights in them, and the purchaser therefore is actually infringing those rights by the making of a single print from the negatives he has bought. Clearly a case of imperfect drafting which badly needs clearing up in the Courts.

* * *

Vertical Camera Stands The value of the vertical camera stand is not so generally appreciated as it should be, this appliance being rarely found except in studios devoted to commercial work. It is a great time saver in many classes of work, as it obviates much labour in arranging small articles or even copies, especially from illustrations, in bound volumes. It has also the advantage of enabling "shadowless" photographs of such subjects as flowers, medals and museum specimens to be readily made. In its simplest form it consists of a stout base-board to which is fixed by iron brackets a vertical board, say three-quarters of an inch thick and eight or nine inches wide, having down the centre a long slot to take the ordinary T screw of the camera. At a convenient height from the floor a glass slab or shelf is supported by blocks or boxes, and below the glass a few inches away is placed a card or sheet of paper of suitable tint, to serve as a background. This arrangement is very suitable for making up compositions of views and flowers, such as are used for birthday and local view cards, as no fixing is required. Also, it is much easier to obtain even lighting in this way than when the originals are fixed vertically as in ordinary copying.

* * *

White Margins. With most trimmers it is difficult to cut the white margin of a print to exactly the same width all round, as the margin is entirely covered while the cut is being made. A useful suggestion is to take a large celluloid set square, as made for draughtsmen, and rule one or more lines at a convenient distance from the edges. If this be placed over the corners of the print the desired width of margin can be marked with a fine hard pencil, and if this line be cut off in the trimmer the margin will be just what is wanted at the first trial. A grey or buff margin can be produced by tinting the paper with the Aerograph. The print being protected by a card, the method saves the expense of tint paper, shellac tissue and time. If an Aerograph be not available, chalk or powdered colour may be rubbed in as quickly and, as nearly all prints are now dry-mounted, without risk of shifting the colour. Blocking out the margins can be done quickly by using a drawing pen charged with any of the ordinary opaques for the inner edge and then filling up with the brush. This is a neater method than attaching strips of lantern binding as is commonly done. In any case the blocking out should be done on the film side of the negative, so as to ensure a sharp edge.

* * *

Window Portraits. Some of the most charming effects in portraiture are those in which a brightly-lighted window forms part of the composition. Many praiseworthy attempts in this direction are spoiled by halation, which is not always evident to the untrained eye. For such subjects backed plates or film should always be used. There is a natural tendency in such conditions to under-exposure, with the result that the high-lights are blocked up in the attempt to secure some trace of detail in the shadows, but this may be avoided if means are taken against halation; what is mistaken for over-exposure in a properly-exposed plate is really halation. A fair amount of reflected light is as necessary in this class of work as when working further in the room, although the necessity is not so evident to the eye. In addition, the persulphate reducer may often be used with advantage. Let it be tried on a hard portrait negative in which the sitter is placed with his back to a brightly-lighted window with white lace curtains, viz., a negative which in the print gives the effect of a quite plain white background. After reduction, not only will the pattern of the curtain be visible, but also all the details of the view outside.

THE SMALL CAMERA.

THERE is a very general distrust, on the part of most professionals, of any camera smaller than half-plate. In these notes we wish to put forward the case for the smaller camera as an addition to the general outfit. We do not believe in the practice of taking all negatives on small plates and enlarging them. Some absurd claims have been made for the small camera on these lines, and we cannot uphold them; but as an extra tool in the photographer's equipment the quarter plate or $3\frac{1}{4}$ x $2\frac{1}{2}$ instrument will prove of great utility. Let us briefly discuss some of its many uses.

Perhaps the outstanding advantage of the small camera is the fact that the lens fitted is, naturally, a short focus one. This, by an unalterable law of optics, means that you can get depth of focus with a larger relative aperture than you can with a long-focus lens. For instance, an 8-in. half-plate lens at $f/8$ will give the same depth of focus as a $4\frac{1}{2}$ in. lens at $f/4.5$. The advantage of the latter in speed is one too obvious to need enlarging on. It is particularly useful in interior work, where near and distant objects must be obtained sharp, and yet long exposures cannot be conveniently given.

The small camera is a decided advantage when it becomes necessary to work in unusual and, perhaps, precarious positions, as, for example, from scaffolding, or from a roof. It is easier to carry, does not need such a large spread of tripod, and is not so likely to be blown over. This last alone often makes it worth while to use a small supplementary camera when taking outdoor views in a wind. Often negatives taken with a whole plate outfit will be blurred, while the smaller instrument, offering less surface to the wind, will be quite steady. Another case where a supplementary camera is most useful is in flashlight. The flashlight negative ruined by the light striking the lens, or by some unexpected brilliant reflection, is common, and a small camera standing perhaps only a few feet away may save the situation. It is really no additional trouble to set up, and the expense of the small plates is not great.

Again, a small camera is a very great improvement on a large one for photography of children and of animals, except, of course, when the work is done in the studio; "nerves" are much less likely to cause trouble, and it is more easy to move your outfit from place to place to follow your subject. This often avoids the stiff formality it is so hard to get rid of when the subject is bound to stay on a certain spot.

One more point: With small plates one feels far more justified in taking pictures "on spec." For instance, if there is a factory in your town it is more than likely that the manager would be pleased to pay for a good set of prints of the various rooms and operations; but the chances are he will not promise an order until he has seen the results. By getting permission to take the pictures, and using a small camera, you are able to do this without interfering with the workmen, and the plates cost only a fraction of the cost of whole-plates.

The negatives are enlarged and a set of prints submitted. They will doubtless be taken, and further orders are bound to follow. Works managers can usually appreciate good photographic work. As nearly all small negatives will be enlarged it is necessary to keep them rather thin and soft. Also, we think a non-staining developer is much to be preferred for small negatives, whatever one's practice with larger ones may be. Sharpness is an essential feature, and a good lens costs comparatively little in a small size.

With regard to the camera a quarter plate or $3\frac{1}{4} \times 2\frac{1}{2}$ outfit with a reversing back is best. We are inclined to prefer the smaller size, and find it most generally useful; as the plates cost only 2s. 6d. per dozen it represents a great saving, even on half-plates. Any lens will do, of course, but an anastigmat of not less than *f* 6 aperture will be found a sound investment. A between-lens shutter, and a view finder and scale for focussing, will further extend its scope, by bringing hand-camera work within its range.

THE PROFESSIONAL'S DEVELOPER.

In common with most of those who have studied photography, the writer has long wondered why the professional is still so faithful to pyro. Its disadvantages are many; are there any compensations? There are three directions in which one might look for special advantages: superior quality of negatives, ease of use, and cheapness. Let us look rather deeper into these three things.

Quality of Negatives.

Years ago it was common to hear people say that the pyro negative had a quality superior to that given by any other developer; but one seldom hears it now. The work of the scientific investigators seems to have demonstrated pretty clearly that as regards the quality of results all developers are alike; and, one thing is certain, the image given by a pyro developer with little sulphite (i.e., the brown "stain image," which is the main difference between the pyro negative and others) does not lend itself so well to after-treatment as the clean silver image of the newer developers.

As regards the question of modifying the developer according to the exposure or the results desired, modern practice seems to be drawing further and further away from this idea; but for those who yet hold to it, pyro is still no different to others, except that for this purpose it is best to use a developer of fairly low "Watkins factor," i.e., one where the first image does not rush out too quickly.

Ease of Use.

Here the comparison is all against pyro. Pyro is essentially a two-solution developer, and is difficult to make up in highly concentrated form. It is usually kept in stock at such a strength that the working developer is made by taking equal parts of the two solutions. This involves lifting two Winchesters, and measuring out of each. With the developer recommended below, all that is done is to turn on a tap, and draw off an ounce or two, to be diluted with water in the ratio of about 1 : 15. The exact degree of dilution is unimportant, except when developing by time and temperature.

Then as regards making up the stock. The usual method is to make a batch of pyro about once a week; with the other, the same quantity will last three months. The job of compounding is slightly more troublesome with pyro, as the metabisulphite of potassium has to be dissolved in the cool.

Comparative Cost.

Lastly, as to cost. Once, pyro was the cheapest developer; pyro itself is still the cheapest to buy by the pound, but is that what is wanted? Any developer can be made cheap, if it is watered down enough. To compare prices, one must adopt some standard of strength, and the obvious one is that it shall fully develop a given plate in some definite time at normal temperature. Here the superior energy of other developers scores heavily. Let us compare two well-known developers for which standard figures are obtainable. Mr. Alfred Watkins has given two formulæ, one for pyro-soda and one for M-Q, both of which develop a medium plate in 6½ minutes at 60 deg. F. On working out the cost of 16 gals. of working strength, at present-day wholesale prices, they are:—Pyro, 17s.; M-Q, 12s. 10d. It is not easy to compare the strength of the author's developer with these, as there is no proof that his idea of normal contrast agrees with that of Mr Watkins'; but working to a contrast suitable for enlarging on bromide, this developer costs 10s. 11d. So there is no doubt as to the advantage of M-Q as regards cost.

Other Advantages.

There is one obvious advantage: the M-Q developer is a universal one, and the fewer bottles on the shelf the better. True, those who must have the particular shade of black on bromides which is given by amidol will not get this advantage; but is amidol really better than M-Q? There was a legend that it gave better sulphide tones, better bromoils, etc., but the writer is not yet convinced.

Another enormous advantage is—no stains. For a studio where the operator does his own developing, it will be as great a relief for him as for his sitters when he need no longer feel ashamed to show his hands. Further, there is less chance of undesired stains on the negatives.

The Designing of the Developer.

When, about six years ago, the writer decided to adopt a single-solution universal developer, he expended considerable thought on the formula for it. It was necessary that it should be obtainable anywhere, so he made no attempt to invent a fancy reducing agent. As, of all the easily obtainable ones, metol *plus* hydroquinone (quinol) had the greatest energy, i.e., developing power per ounce, and as it had only one disadvantage it was obviously the one to be adopted. The one disadvantage, metol poisoning, did not bother the writer. For those who suffer from it, it will be found that the substitution of paramidophenol for metol, in equal quantities, will give an almost exactly similar developer, but slightly less powerful at the same dilution.

Proportion of Metol to Hydroquinone.

Hydroquinone being cheaper than metol, one is inclined to use a larger amount of it. But it is to be remembered that the "convenience" of the developer in use, as also its extreme energy, is due to the metol bringing out very quickly a weak image, on which the hydroquinone builds up the density; further, one must remember that in the cold the hydroquinone loses power rather quickly. These considerations, together with some experiments, led the writer to adopt finally a ratio of one part metol to two parts hydroquinone.

The Amount of Sulphite.

This was entirely a matter of experiment, and the result was to the effect that the sulphite should be about six times the reducing agent. This is sufficient to keep the concentrated developer good for a long time; but if it is proposed to leave dilute developer exposed for more than half an hour or so, it must be increased

Proportion of Alkali.

As regards alkali, the writer breaks away from the usual type of M-Q developer: caustic soda is used. From all that could be gathered by reading on the subject, the sole object of the alkali appeared to be its alkaline reaction. Why, then, not use a small quantity of a strong one rather than much of a weak one? There are two advantages: the caustic soda is itself a solvent of the reducing agent, and only one-twelfth as much caustic as carbonate is needed. The net result is a concentrated developer, and on experimenting it was found to result in a considerable increase in the energy, thereby giving an even greater effective concentration.

Sheppard and Mees show that there is a definite proportion of alkali that gives the most chemically efficient developer, but, curiously enough, this is not the cheapest. A slight increase of soda and decrease of reducer cause a very slight decrease of speed, and a very much greater decrease of cost. The proportion ultimately found best is that given.

The Final Formula.

When the proportions were all worked out it was realised that it needed a wide variation from the theoretical best before any ill-effect was found, so the proportions were rounded off to give a formula which could be easily remembered, and which could to a large extent be made up from chemicals in packages as bought without weighing. The final formula was:—

Metol	¼ lb.
Hydroquinone	½ lb.
Soda sulphite	2 lbs.
Soda hydroxide (caustic soda)	1 lb.
Water	to 2 gals. (320 ozs.)

Dilute one part with 10 to 15 water.

NOTE.—There is no need to pay fancy prices for "stick" caustic soda; at least one London house supplies chip soda, guaranteed 98 per cent. pure, at a very low price.

For those who use thermo, or factorial development, the following may be useful. They refer to medium contrast, and should probably be diminished somewhat for portraits:—

Watkins factor.—12 to 15.

Thermo development.—Develops a plate given by Watkins as Class "M" for development speed in six minutes at 60 deg. F., when diluted 1 in 12. Temperature coefficient, 1.9 (approximate).

Time for other dilutions, multiply by:—

Strength...	1 in 6.	1 in 8.	1 in 12.	1 in 16.	1 in 24.
	2/5	4/7	1	1½	2½

Keeping the Developer.

The best way to keep the developer is to get a 2-gallon glass bottle with "tubulure," as used by chemists, i.e., with a second neck at the bottom, to be fitted with a tap. These are often known as "aspirators." To keep the developer from oxidising, the cork is fitted with a glass tube, which should lead to a gas tap provided for it, which is always kept turned on. Under these conditions the developer as drawn off is replaced by gas instead of air, and the stock will remain unoxidised and unchanged for a year or more.

If gas is not available, the cork should be connected to an "oxygen trap," which consists of a 4-oz. "wash-bottle," which any chemist will supply, half-filled with full strength developer *with no sulphite*. This will become oxidised, but will protect the rest of the developer (or, more simply, bottle in lots of, say, 10 ozs.—EDS. "B.J.")

The writer fully realises that the professional cannot lightly make changes in important operations; but it is claimed that the enormous gain in convenience by using the above developer, and keeping it as suggested, makes the proposition worthy of serious consideration by the professional.

P. M. JONES.

NOTES ON MOUNTING.

To an onlooker, the mounting of a photograph might seem too simple to need instructions and too trivial to merit discussion, but anyone who has had years of close connection with photography will agree that there is much more in mounting than "sticking a print on to a piece of cardboard."

Mounting, to be good, requires considering from at least two sides, the artistic and the technical, and unless we happen to be wealthy amateurs, we must also remember the £ s. d. standpoint.

The Artistic Side.

For every photograph a mount can be made or bought that will, by reason of its colour and design, show up the particular photograph to best advantage. And mounts innumerable can be made and bought that can do neither credit nor justice to the same picture.

Should mounts be bought ready made, or is it better to build up one's own? There are certain advantages either way. The mount manufacturer has resources at his command that make it impossible for the photographer to imitate his products; and if our work is in a definite and regular style, with a constant quality and tone, we are certain to find something on the market that is superior and more suitable than anything we could make ourselves. But for work that varies in contrast, key or tone, there is much to be said for built-up mounts designed deliberately for individual photographs or orders.

There are no universal rules determining what colours or shades can or cannot be used on a mounting job. Some workers restrict themselves to the use of tints which are in agreement with the print, and for a cold black and white would not touch anything outside of black, white, green and bluey greys. For warm black and sepia work this school would only use white, buff, cream and brown. Others will combine cold and warm tints in the same mount for either a black or brown picture, often with excellent results, but where there is any doubt the first mentioned system is the safer. With prints that need no improvement, either in depth, contrast or colour, there is a greater choice of mount shades than with work that is not quite all that it might be.

A faulty picture can be made to look much better—or much worse—than it is by its mount. To render a fault inconspicuous, or to make poor quality appear to be quite "the thing," the usual plan is to "go one worse" with the mount. For examples:—A certain print has extremely black blacks; it would have been more to our liking with warmer blacks. We mount it on blue-black against which it appears warm in comparison. To put it on anything warm would only enhance its cold blackness and so make it worse. A sepia is "mustardy." Mount it on pale brown, buff, cream or coffee and it will probably appear all right, but to put it against a rich vandyke brown will convict it on the spot. Exceptionally disagreeable tones can sometimes be made to look exceptionally artistic by mounting on the same (exact) shade. A photograph that is dark should be put on a darker mount. On a white one such a print would seem darker again than it really is. The same principle applies to a pale picture, which requires a pale mount if it is not to appear bleached or faded. A soot and chalk type of print needs a contrasty mount, e.g., white with black tint, and a soft or flat print will go best on a combination of very near tints, e.g., deep cream and buff or light grey and medium grey.

Pencil and brush can be useful in mount making, but they are not taken any great advantage of. For good work where the design of a mount is not required to bolster up the print, very natty effects are obtainable by lines in pencil, ink and water colour. A fine border, if done neatly and accurately, is often more effective than any tinting scheme. Fine border lines in gold paint on a rich brown are very attractive.

The most suitable size for a mount is best found by experiment, particularly if the picture is long in comparison with its width or of an oval or circular shape. For standard-sized pictures the sizes favoured by manufacturers are quite suitable for all but exceptional orders. The position of the picture should always be slightly above the true centre if the mounted result is not to appear pushed down or squat. It is a general rule to have the side spaces precisely equal, but if the subject is such that a print looks well placed when decidedly to one side there can be no objection to mounting it so. But such a departure must be definite. There must be no suggestion that the result is merely due to crooked sight on the mounter's part. I have known an odd occasion when a head portrait looking towards the bottom right-hand corner of the print, was advantageously mounted in the top left corner of the mount, the tint showing slightly wider on the right and bottom sides.

I am not an advocate of plate marks, but for those who like them there is a fairly simple way of making any desired size. The requirements are two pieces of thin mounting board (4 to 6 sheet) slightly larger than the size of mount to be marked, and some *paste-portout* binding. With a mount placed between them, the two cards are bound along one edge. When the binding is set the inner face of one card is marked in pencil with the desired size for the plate mark, and after making sure that the corners are square and that the mark is central, the lines are gone over with a very sharp knife guided by a straight-edge. When the piece has been cut cleanly out, a few drops of seccotine are rubbed on to it (without removing it), and the other card is folded over and the whole left under a weight until the adhesive has set. The centre square will now be attached to the top card and will lift out of its original opening when the cards are opened. A mount placed between the two and pressed in the dry-mounting machine for a few seconds will be neatly plate-marked. If there is no machine available the effect can be got—but not so quickly—by pressure under a gross or so of large mounts or other large flat weight.

Cut-out and flush bevel mounts are applicable to a large variety of photographs, and have their points. The former, particularly in delicate shades, give quite a distinctive appearance to good pictures of any size. Rectangular cut-outs are done by hand with the knife, but are not difficult if a good edge is kept. Ovals and circles require much more care and patience; but for these, machines can be obtained that eliminate the factor of manual dexterity. Bevel mounts can be cut on a special board or in the same way as square cut-outs. They are perhaps the simplest mounts of all, as they merely add stiffness, substance and finish to a picture without effecting its spectacular quality.

The Technical Side.

The substances that can be used for attaching a photograph to its mount are numerous. I will deal only with the most important, which are starch paste, proprietary pastes, gelatine, Seccotine, gum arabic, and shellac. Starch paste, if properly made, is a strong, clean and safe mountant which sets into a hard and durable binding. Provided that no traces are allowed to dry on the face of the print or mount, starch is quite satisfactory as a mounting agent. Prints can be mounted with it in a dry or wet state, the latter being the easiest and most usual way. Proprietary pastes of good makes are very similar to starch, and can be used with confidence. Gelatine, made in a thick, warm solution, is a very strong mountant that can be used on dry prints. It can be prepared by dissolving gelatine in warm water to get a thick syrupy liquor which is thinned down sufficiently for use by heating without the addition of water. "Seccotine," let down with water, makes a clean mountant. Whether it is liable to produce any after effects I cannot say. I have used it myself without so far coming across any symptoms. Used as it comes from the tube, it will mount thick papers if spread thinly along the edges of the dry prints. Gum arabic, prepared by hanging a bag of crystals or dust in a bottle of cold water until sufficient has dissolved to make a thick gum, can be used on dry or wet prints, but does not stick so readily as gelatine or "Seccotine."

Shellac dissolved in methylated spirit will mount dry prints cold or hot. In its well-known form of tissue it provides what is probably the most popular system of mounting at the present time. When using tissue, the right temperature is of paramount importance. This varies with different batches, and the correct degree should be found by experiment when starting on a fresh lot. By keeping a small thermometer on the dry-mounting machine, work is greatly facilitated, once the best temperature for the tissue in use is known. After using large quantities of present-day tissue, I am of the opinion that it is not as good in the aggregate as other photographic products. Perhaps I am too exacting, but in any case tissue has the advantages of being clean and dry to handle and innocuous and protective to the print. Dry-mounting can be done with a large flat iron where no machine is available.

With dry or wet mounting, the actual degree of humidity of the print is a matter of some importance. In the first case prints must be really dry to avoid risk of the surface sticking to the zinc plate or blotting paper, whichever is used to cover. If there is any doubt on the point, a print can be put in the mounter, or under the flat iron and given a momentary press, which will remove any dampness before there is time for sticking. In wet mounting prints must be thoroughly and evenly wet. If they are not properly soaked the expansion due to wetting will be uneven, and they may dry up not truly square. Some workers trim their prints wet to avoid this, but there is no necessity to take the extra risk if care is taken to soak prints thoroughly before wet-mounting. At the moment of pasting, however, there should be no surplus moisture. A print that is pasted while covered with water is not likely to stick well, as the paste will be greatly diluted. Another thing, the paste and water will be apt to roll out under pressure and deface the mount. When rolled down quite flat, mounted prints should be left under pressure for some little time unless the adhesive is known to be very strong, when they can be safely left exposed to the air, in which condition they will dry more rapidly. In either case pressure or restraint of some kind is wanted *on the mount* to prevent cockling, which is the bugbear of wet-mounting.

The keeping qualities of mountants are uncertain properties. Pastes are best when freshly made, but will keep for long periods if a preservative is present. I have used chloroform and chloroform water for preserving pastes with good results. Proprietary pastes always contain preservative, and should keep for a reasonable time. Dry-mounting tissue is said by some to be subject to the air, and to lose its adhesive properties if left lying about or in uncovered boxes. Whilst I cannot corroborate this from experience, it sounds feasible, but the remedy—or prevention—is obvious and simple.

The Business Point of View.

When mounting is done on a large scale, and particularly if done for profit, i.e., professionally, the £ s. d. point of view is important. By studying different manufacturers' catalogues it will be found that a style or variety of mounting may be carried out at different figures. It will also become apparent that certain styles of made mounts will prove cheaper or dearer than similar or equally serviceable styles made up from boards and tints. With cut-outs and bevels we have to take into consideration time and labour on one hand, and the advantage of buying quantities of large boards and the possibilities of economical cutting on the other. For example, a 15×12 cut-out may take up a little time and necessitate some skill to cut, but it may be made from comparatively

cheap board and still be effective, and the centre-piece will make another mount for a smaller picture. To have a substantial result, the prints should first be rough-mounted, of course, but this can be done on waste mounts or thin cardboard or thick tint board, and need not add very much to the cost. For two cut-outs, one 15×12 and the other 10×8 we would require one piece of board about 24×18, two old mounts or pieces of thick tint about 16×13 and 11×10, two sheets of dry-mounting tissue, 15×12 and 10×8, about threepennyworth of "Seccotine," and the necessary labour and time. For good work we can add brown paper and a trace more "Seccotine" to back the mounts. To work out the cost of such a job from a wholesale price-list of mounts, and then compare it with the cost when using various made mounts, keeping in mind the artistic side of the question, would provide a good example of how useful business methods may be. It must always be remembered though that to buy consistently in the cheapest markets is risky, and to sacrifice artistic quality to cost may prove the dearer way in the end. To maintain technical and artistic excellence without unnecessary outlay should be the aim of anyone undertaking mounting on a business scale.

THERMIT.

PHOTO-STEREO-SYNTHESIS: THE PHOTOGRAPHIC REPRESENTATION OF A SOLID OBJECT.

[Students of photography have been so accustomed to associate the names of the brothers Lumière with chemical investigations into photographic processes that it is perhaps overlooked that MM. Lumière have long taken an interest in the optical side of photography. Their share in the origination of the cinematograph projector is their most notable contribution to this branch of photography: another piece of original work which has proved less fruitful is the stereo-photo-diorama, devised by them some years ago. In the following paper by M. Louis Lumière, contributed to the Academy of Sciences and recently published in "Comptes Rendus," the theory and practice of a method of producing a single photographic representation of a solid object are described. The result obtained by the method which is here set forth consists of several positive transparencies representing successive planes of the subject, and mounted one behind another at intervals proportional to their separation in the subject and to the scale of reproduction. The set of transparencies, when viewed by a strong transmitted light from a chosen standpoint, produces the sensation of solidity in a striking manner.—Eds. "B.J."]

If photographic negatives are taken, on a fixed scale of reproduction, of a series of parallel planes (equidistant or otherwise) of an object, whilst fulfilling the condition that each image represents only the intersection of the object by the corresponding plane, it will be possible, by superimposing the positive images made from the negatives obtained in this way, to re-form in space the appearance of the object photographed. For this it is sufficient that the distances of the positive images are equal to those of the planes photographed modified by a coefficient corresponding with the scale employed.

For a theoretically perfect reproduction it would be necessary to superimpose an infinite number of images differing from each other to an infinitesimal degree, but experiment has shown that this condition, which obviously cannot be fulfilled in practice, is not necessary in order to convey to the eye the impression of continuity: a small number of elements is sufficient if, within certain limits, each image corresponds not with a plane, which likewise cannot be done in practice, but with a given focal volume. This focal volume should, however, be fairly small if it is desired to avoid parallax effects.

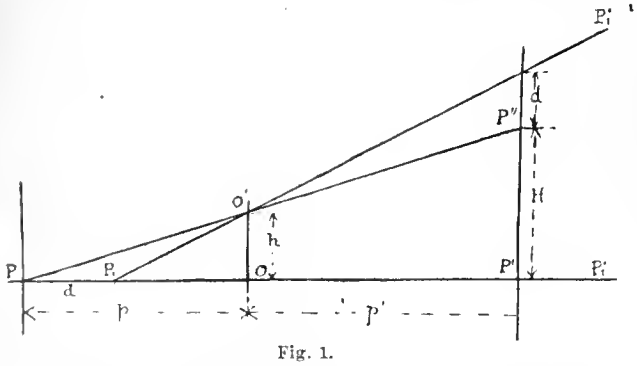

Fig. 1.

If the attempt is made to effect this reproduction by means of a lens possessing the maximum relative aperture which is possible, it is found that the depth of field is still much too great.

In order to obtain the necessary reduction of the focal volume, I have devised two methods, based upon the following considerations:—

(1) In fig. 1 let O be a lens of flat field producing an image P′ of a point P situated on the principal axis. If the lens be displaced so that its axis remains parallel to itself to a distance h and so that its principal planes remain in the same position in space, the image P′ will come into the position P″, situated in the image plane conjugate to the object plane which contains the point P.

If, at the same time, the image plane be moved in the same direction and without rotation on itself through a distance H such that

$$\frac{h}{H} = \frac{p}{p+p}$$

the position of the image of the point P will not have changed relatively to the limits of this plane. It can be easily shown that this will be the case also with every point situated in the object plane conjugate to the image plane.

It will, however, not be the case with points such as P, situated nearer to or further from the object plane. At each distance d of this plane there will be a corresponding displacement d' of the curve of the secondary axis corresponding on the image plane, and the value of d' will be given by the formula—

$$d' = \frac{h\,p'}{p-d} - H - h$$

The image of the point P will thus yield on the sensitive surface a curve of length d'.

It is easy to see that there is an advantage in making the ratio $p : p'$ as small as possible, in making h on the other hand of as high a value as possible and in selecting a very small value for f. But the conditions of reproduction in practice limit the choice of these factors. Unless a sensitive surface of enormous dimensions be employed, there is the necessity of adopting a value of $p : p'$ of less than 1, whilst f cannot be less than about 20 cm.

(2) In fig. 2, O is the lens provided with a reversing prism and forming the image P′ of the point P, p and p' being necessarily equal, having regard to the prolongation arising from the interposition of the prism.

If this lens be subjected to displacement of any amplitude whilst taking the precaution to effect the displacement in the plane of the principal section of the prism, and if this plane,

as well as the principal planes of the lens, remains unaltered in position in space, the position P′ of the image of the point P will not undergo alteration. On the other hand, the image of any point nearer to or further from the image plane will undergo displacements in accordance with the formula already set forth. Thus, for reduction of the focal volume, it will be sufficient to provide the lens with two reversing prisms, the principal sections of which are at an angle of 90 deg., and

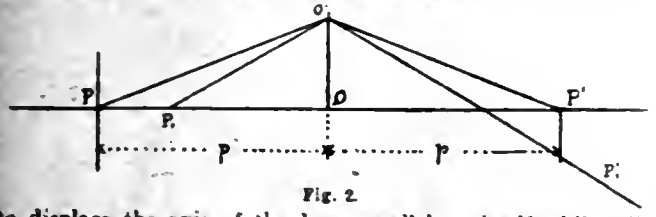

Fig. 2.

to displace the axis of the lens parallel to itself whilst likewise keeping the principal sections parallel to themselves during displacement.*

For the application of these theoretical principles I first constructed an apparatus on the lines of (2), which appeared to me most susceptible of a practical form.

A board A (fig. 3), capable of sliding in its own plane on the front of a photographic camera, is caused to move so that

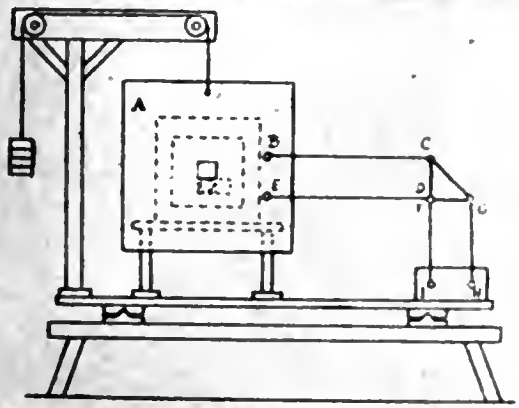

Fig. 3.

its sides remain constantly parallel to themselves by the operation of the linked system B C D E and F G H I. It carries at its centre a lens fitted with two Porro prisms arranged relatively to each other as shown in fig. 4, the principal section of the front prism being perpendicular to that of the rear prism, and the extension of the camera, which completes the apparatus, being such that the condition $p=p'$ is fulfilled. The whole apparatus is mounted on rails which allow of it

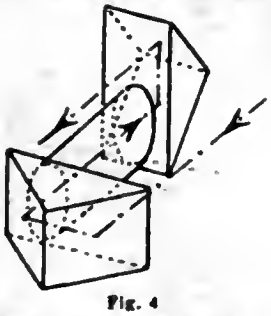

Fig. 4

being moved towards or away from the object to be photographed for the purpose of placing it in the successive positions corresponding with the series of planes chosen for the making of the negatives.

By moving the lens board during the exposure the definition of points not corresponding with the condition $p=p'$ is affected.

In default of prisms cut in the required manner, the images which I obtained were not altogether satisfactory, and I therefore constructed the apparatus represented in fig. 3, which is on the lines of (1) above.

Two frames, each affording a large opening, are connected by cross bars, not shown in the drawing.

These frames permit of the passage of four spindles A B C D, each of which is provided at its extremity with a crank piece. To each of these cranks is fitted a pivot, and the ratio of the lengths of the arms of the front and rear crank is equal to

$$\frac{p}{p+p'}$$

The four front pivots engage in sockets fixed in the lens board, and, similarly, the four rear pivots support a second board to which is attached the back body of the camera. The two boards are connected by a bellows which fits light-tight at each end. Lastly, one of the spindles carries a pulley, by means of which, during the exposure, a rotating movement may be given to the whole system by the device shown in the drawing.

From the considerations which have already been set forth, it will be clear that every point beyond the object plane conjugate to the image plane corresponding with the ratio $p:p'$

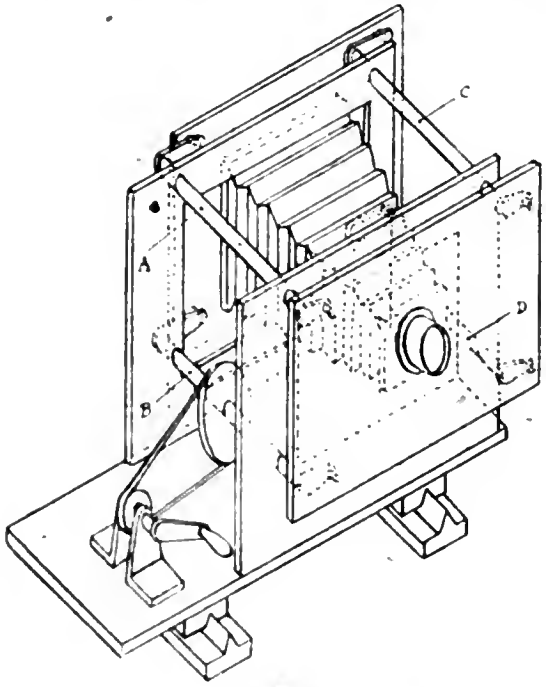

Fig. 5.

yields on the sensitive plate a circular curve, the diameter of which is greater in proportion as the point is at a greater distance from the object plane. Moreover, the circle of confusion corresponding with the aperture of the lens adds its effect in diffusing the definition of this point. Only the points situated in the image plane conjugate to the object plane are sharply rendered.

The angular aperture of the lenses which can be used, by taking a high value for h, would permit of limiting the depth of definition to a small volume, but experience shows that it is scarcely possible to exceed, for the circumference described by the lens, a diameter greater than 80 mm., otherwise, on synthesis of the positive images there is produced a species of conical anamorphosis which completely alters the appearance of the result obtained. This effect appears to be due to the fact that for a given definition the focal volume is greater for points situated beyond the object plane than for those on the near side of this plane.

Whether this is so or not, by choosing suitable values for the different factors and by using a lens of large relative aperture, the apparatus permits of the production of practical results.

LOUIS LUMIÈRE.

*It follows from this arrangement that it is possible to photograph a surface of any given extent by means of a lens of any focal length, e.g., of very small focal length relatively to the dimensions of the surface.

THE PANCHROMATIC PLATE.

It is now about fourteen years since Messrs. Wratten & Wainwright offered to photographers their first panchromatic plates, and gave to the world an improved material which may be regarded as one of the most important advances in photographic science since the advent of the dry-plate. So important, indeed, has this type of plate proved itself to be that it has been the means of opening up new departments of photographic industry, and giving to the printing world a revolutionary advance in the art of colour reproduction. To the professional photographer it has offered golden opportunities, but, unfortunately, his proverbial conservatism has caused him to neglect its general use to such an extent that one is led to ask the reason why?

The answers will necessarily vary with conditions. One will say, "I so rarely have any paintings to copy or valuable furniture to photograph that it is not worth while putting in a safelight for panchromatic work." To such I would reply, you do not require a safelight. Total darkness is cheaper and much more reliable, if not so convenient, but for casual, infrequent use a safelight is quite unnecessary, as will later be observed. Another will say, "My business deals entirely with portraiture, and therefore I have no use for panchromatic plates." In portraiture these plates are eminently successful and useful! Their rapidity has been increased so enormously that quite short exposures are now possible even with a light-filter, so that the chief practical objection to their use no longer exists. A frequent excuse is failure to obtain uniform results, the negatives being often so dense that reduction has been necessary, and the printing quality has not then been up to the standard requirements. The remedy for this is a closer acquaintance with methods of development, and the strict adherence to a method which found to fulfil the condition desired. It is only reasonable to expect that minor difficulties will sometimes arise in every one's early experience in panchromatic as in other photographic work, but in general practice they are rarely repeated; if they should be, the cause is generally obvious and easily remedied, never being of a nature which would disturb the equanimity of an expert photographer for a moment.

There is one thing which is more than a certainty, and it is this: if photographers would only give panchromatic plates the fair trial which they have the right to claim, not one of them would return to the general use of ordinary plates. They can be used for practically every purpose for which ordinary non-colour-sensitive plates are now employed, and for many purposes for which those plates are either absolutely useless or so totally unsuitable that a comparison of the results obtained would always give the first choice to those taken on the pan' plates. This adaptability is so unquestionable as to deserve serious consideration. In the hands of an expert they so increase the commercial value of his capacity and ability as a photographer that his work becomes Photography in capital letters. In the portrait studio the manner in which they reproduce the subtle differences of tints and shades of the various colours of drapery, and the delightful way in which flesh tones are rendered, even without the intervention of a light-filter, makes their use a real pleasure to the photographer who is discriminating in these matters; but, still further, their employment with a suitable light-filter, one specially selected for the requirements of the moment, produce results which appear truly remarkable to the ordinary plate worker.

Here we have a fair sitter who is deeply sunburned after her seaside holiday. Her face and arms are freckled. Her hands and portions of her neck and chest are patchy in shades of reddish brown from continued exposure to sun and breeze. Her hair is rich auburn in colour. Her dress is delicate shade of blue. We all know what an ordinary plate negative of her will appear like, and extend our sympathies to the poor individual who has of necessity to remove laboriously those thousand and one freckles, and work out by tedious retouching those dark, disfiguring patches, to say nothing of the risk of losing the likeness in the process. But here is a negative of the same sitter taken upon a pan' plate with a suitable light-filter. There are no freckles or dark patches here. Her auburn hair is full of detail and sheen. The general tone of the image is soft and delicate, and the work for the retoucher is practically *nil*. The soft folds of her blue dress are not represented as if composed of white calico, but by a scale of rich, subtle tones, with here and there a pleasing high-light, which must be seen to be appreciated. A child dressed in a scarlet cloak or a small boy in a suit of claret-coloured velvet photographed upon an ordinary plate makes a picture which is anything but pleasing. So deep are the tones of the clothing that any little detail which may be there is swallowed up in blackness. How differently a panchromatic plate reproduces these rich colours, and with what a wealth of detail. The old-time advice that children and young ladies should be photographed in white or light-coloured attire is superfluous when pan' plates are used for studio portraiture; and the same remark will, of course, apply also to outdoor groups. In landscape work, in the photographing of garden scenes, conservatories and other places where the infinite variety of rich colouring in flower and foliage presents such a gorgeous display to the eye; to all this brilliance the ordinary plate is blind; while the panchromatic, with a suitably selected filter, will see it and record the effect with all the vividness which gives such pleasure to the observer. In interior work in the homes of the wealthy, where noble pictures and tapestries line the walls, where choice furniture, rich upholstery and carpets of wonderful colouring and design furnish the rooms, the pan' plate alone can satisfy the requirements of the discriminating and give a rendering of colour and detail which will be approximative to the effect which the actual scene has upon the minds of those who use these apartments daily, and who are therefore likely to severely criticise, if not reject, photographs which do not reprodnce these effects faithfully and correctly.

The value of the panchromatic plate in the photographing of furniture, artistic china and bric-à-brac cannot be overestimated. Take, for instance, a piece composed of maple wood or burr walnut, with their wonderful grains, or of Honduras mahogany, for which the ordinary plate is absolutely useless. One trial exposure on a piece of furniture made in any of these woods upon a pan' plate will convert the most conservative worker, and show him that he will be hopelessly out of the running if he expects to retain his reputation for clever photography by the sole use of ordinary colour-blind plates. In copying coloured or stained prints or engravings, red toned photographs in silver or carbon, nothing can equal the result which is to be obtained on panchromatic plates. So that it will be clear, even to the most casual mind, that this variety of plate can do everything for which ordinary plates are usually employed, and at the same time do it better than the ordinary plate; and, further, that it can do many things which the ordinary plate could not possibly accomplish under any circumstances. This being so, the question arises: why use any but panchromatic plates? For some special work, certainly, transparency plates will be necessary, and when copying drawings or plans in pencil or ink a required hardness of contrast can only be obtained on a slow process plate, but for practically every other purpose panchromatic plates will fulfil every condition which a photographer may expect from a dry-plate, and, generally speaking, it is calculated to give a better negative, requiring less after treatment, and in portraiture infinitely less retouching, yielding a richer contact print than ordinary plate negatives, and an unequalled result by enlargement, owing to the high quality of the emulsion with which these plates are invariably coated.

A brief *résumé* of the practical manipulation of these plates

will probably be of interest to many who have not yet used them, and may possibly be helpful to some who have not been as successful in their use as they would naturally desire. Perfection can only be obtained by experience, but one may be helped toward its attainment by the suggestions of those who have gained a measure of success. Now in order to get the full value out of the employment of panchromatic plates it is first necessary to give a litle thought to light-filters. As a means of correcting such colours as blue, green and yellow, the K filters of commerce are too well known to be more than mentioned here; but for general all-round work other filters will be necessary, such as a brilliant yellow, two or three shades of red-orange. A good red and a couple of tints of green are also useful, particularly in the copying of some much discoloured paintings or tapestries, in which a false colour rendering is often the only means by which the detail can be made to appear. The red filter will also prove useful in rendering the grain of dark coloured woods such as polished Honduras mahogany or walnut. In some instances the deeper shades of K filters will fill most of these requirements, but in the writer's experience a full range of practical colours and tints should be available for a general practice.

In portraiture a pink-orange filter will give cleaner flesh and a more acceptable result when photographing a very florid complexioned person, and with less exposure than would be necessary with a filter of the K variety deep enough to give the amount of correction desired. This tint of filter will also render red hair much more satisfactorily. Of course, the amount of red in the filter must be very little when used for a normal complexioned person with red hair, otherwise the flesh will appear anæmic and pasty. Experience in such matters as this is the only safe guide. One should be able to make one's own special filters in order to meet individual requirements. A few careful experiments will make the value of this suggestion obvious. I have said that pan' plates may be used without a light-filter, and in many instances sufficient colour correction will be obtained in this way, but a filter, however pale in tint, will naturally give a better correction. The question of employing very pale tinted filters applies only to portraiture. For general colour rendering there is a minimum of correction below which it is naturally inadvisable to work; the standard K1 filter being a good minimum depth of tint upon which to base any experiments in the direction of filter making in other colours; but to consider maximum depths of colour one would refer to the filters employed in three-colour work, which the writer has constantly used for commercial photography in monochrome.

The exposure of panchromatic plates under various conditions of light will not at first be as simple for all purposes as one would wish; but here again experience and a careful observation of conditions will soon enable the worker to overcome any difficulties in this respect. It must be remembered that when working in the daylight of autumn or winter time the colour of the light varies between blue, yellow and red, according to the time of the day and the state of the atmosphere. In the spring and summer time the prevailing rays in the light are the blue ones, except toward the closing hours of daylight, when the yellow and red rays will more and more assert themselves. Here we have the principal reason why ordinary plates require such long exposures under adverse conditions of daylight, to the colour of which they are insensitive, and here it is that the panchromatic plate naturally scores, because it is sensitive to these colours, and a comparatively short exposure can be given, no light-filter being necessary, say, for outdoor groups or animals when it is required to take such subjects in waning or bad coloured daylight. Nothing but practice and observation will, however, enable one to arrive at correct exposures under all lighting conditions, but no operator of experience will anticipate great difficulty in so familiar surroundings, remembering that these plates are sensitive to colour other than blue. I wish to make it clear to the inexperienced that the principles involved in the manipulation of pan' plates are no more difficult to grasp and apply than those which govern ordinary colour-blind photography, but it must be remarked that at first the element of uncertainty of the correct amount of exposure necessary, say, in the copying of old paintings or the photographing of dark, richly coloured interiors, is almost as great to the novice in pan' work as ordinary photography, minus a light-meter, is to the merest tyro.

The dark-room and the work in it now demand consideration. It will be readily understood that our old-time friend, the ruby lamp, is quite useless for dark-room illumination with panchromatic plates. So sensitive are they to this light that it is possible to take a photograph in light of the old familiar ruby colour. When it is necessary to employ a light in the dark-room during development it must naturally be one to which the pan' plate is least sensitive. So-called safe lights are procurable from any good dealer or trade house which are quite reliable for the purpose of locating objects in the room, but under no circumstances should rapid panchromatic plates be exposed even to these subdued and comparatively non-actinic rays. There are no rays of actual visible light to which these plates are not highly sensitive. Hence it is essential that all laboratory work shall be carried out in practical darkness. Dark slides should always be filled in total darkness.

The section of the dark-room which is devoted to developing operations must be screened even from a "safelight," so that the plate which is being developed is continually in total darkness until fixation is complete, or fog veiling will almost inevitably be observable in the fixed negative. A sufficient quantity of developer must be used which will ensure that the plate is completely covered without it being necessary to make any kind of examination in order to satisfy one's mind in this respect.

It is often said that it is unfair to the manufacturers of plates, and other material requiring development, if the formulæ and instructions which they publish for the development of their products are not accepted as most suitable and undeviatingly employed in order to obtain successful results. Admitted that dry-plate makers put themselves to considerable trouble and expense in order to arrive at the conclusions which their published data for development express, yet I think that their responsible chemist would be the last to claim a knowledge of the idiosyncrasies discoverable in the productions of their firm which would be superior to that of a man who employs those products in constant daily practice. Many years of experience in practical photography tends to make one independent of published formulæ. Liberty of action is the acme of true freedom, but in a photographic sense this desire for liberty may often become a snare, and unless one has some practical knowledge of chemical action and reaction it is always advisable to follow implicitly the makers' instructions for development. At the same time I will venture to suggest a development method which has been proved to be eminently successful with "Wratten" plates. It is not claimed that the method is unique or distinctive, but it is calculated to give a uniformity of result which is rarely seen by any other method. It must be remembered that one is unable to examine the progress of development of pan' plates, and that it is necessary to develop a faith in the means which it is proposed to employ before commencing operations.

Metol-hydroquinone-soda is a developing combination not particularly favoured by professional photographers, but it is one which the writer has used with Wratten plates for many years with success. The formula is as follows:—

(1)	Metol or substitute	90 grs.
	Sodium sulphite	2 ozs.
	Warm water	20 ozs.
(2)	Hydroquinone	20 grs.
	Sodium sulphite	1 oz.
	Water	20 ozs.
(3)	Sodium carbonate	540 grs.
	Sodium sulphite	1½ ozs.
	Water	20 ozs.

For portraiture, still life studies, interiors, etc., where a

soft negative is desired, mix together equal quantities of Nos. 1, 2 and 3, and to every 2 ozs. of developer add 1 oz. of water hot enough to raise the temperature of the developer to 70 deg. F. Meanwhile, the developing dish should have been warmed by having water of 80 deg. F. poured into it. Being now ready to develop, and having poured the warm water out of the developing dish and placed the exposed plate in the dish in total darkness, pour on the developer and develop for five minutes, timing the same by means of a dark-room clock or, preferably and more conveniently, by means of a Radiolite wrist watch. Having rinsed the plate in cold water and wiped off with a dry cloth the backing material (if backed plates are being used), transfer the negative to the fixing bath.

Hypo, 4 ozs. Water, 20 ozs.

The fixing bath should be shielded from light until fixation is complete.

For developing negatives of landscapes or other subjects where a greater density and contrast is desired, mix together 1 part of No. 1, 1½ parts of No. 2, 1 part of No. 3, adding hot water as before, and 1 drop of 10 per cent. potassium bromide to each ounce of developer, proceeding as before suggested, but continuing development for six minutes.

It has been found that samples of hydroquinone vary in their desity-giving qualities. This is one of the objections to its use. Should there be excessive contrast in a negative, reduce the amount of hydroquinone and bromide. If it is merely dense, reduce the time of development. This developer is a very useful one when one has become accustomed to its use, because any degree of softness or contrast is obtainable at will, and having decided upon a mixture and time of development suited to our requirements, and given correctly exposed plates, the quality and strength of the resulting negatives will be remarkably uniform.

The following notes should be remembered. It is always advisable to use backed plates.

New plates will always be more colour-sensitive than stale ones. It is a good practice to write the date of purchase upon each box of plates as they are delivered. This will often obviate disappointment. Stale plates should be reserved for copying purposes or for landscape work if they have not been kept too long.

A single plate should not be repacked with the film in contact with the packing paper, otherwise it will soon become useless. In order to avoid this, keep an undeveloped plate of doubtful character always to hand, so that it may be used to pack film to film with the pan' plate. Stick a piece of paper on the back of the dud plate for identification, and see that it is free from dust before using. Though it may have lost its own reputation for the purpose for which it was originally intended, it may be the means of keeping many plates of good character from losing their reputation.

Do not use a developer more than once if you wish to make negatives of a uniform quality. The developer suggested contains so small a quantity of developing material that it becomes practically exhausted by once being used. A second negative developed in a warmed-up developer requires a longer time to acquire density.

Use a dairy thermometer for testing the temperature of water and developer. It is sold in wooden cases by people who supply farmers and dairymen with their utensils, and is quite a low-priced article.

Keep the fingers off the developed film until it is dry. The warm developer softens it and makes it very liable to damage.

Do not be tempted to examine a plate, even by a safelight, during development. Failure comes that way.

Panchromatic plates give a fair amount of latitude in exposure, but they do best with a full minimum exposure rather than an over-exposure. This latter should be avoided.

It will be seen that there is something new to learn, new reasons why to consider, new methods to employ, and new ground to cover; but it will always be worth while, because it will bring new business and increased emolument, considerations which will certainly appeal to all professional photographers, both employer and assistant.

HENRY J. COMLEY.

FORTHCOMING EXHIBITIONS.

February 19 to March 5.—Edinburgh Photographic Society. Particulars from the Hon. Secretary, G. Massie, 10, Hart Street, Edinburgh.

February 19 to March 12.—Scottish Salon, Dundee. Particulars from the Hon. Secretary, James Slater, Rosemount, Camphill Road, Broughty Ferry.

March 16 to 19.—Hackney Photographic Society. Latest date for entries, March 1. Particulars from the Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 13 to 23.—Portsmouth Camera Club. Latest date for entries March 31. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

April 15 to 23.—Professional Photographers' Association, at the Photographic Fair, Horticultural Hall, Westminster, S.W. Hon. Secretary. Marcus Adams, 83, White Knights Road, Earley, Reading.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Latest date for entries, March 17. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Latest date for entries, April 16. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs.

AERIAL PHOTOGRAPHIC MAP OF LONDON.—According to an aeronautical correspondent of "The Times," the project for a photographic map of the whole of London, taken from the air, has now advanced sufficiently for a series of test sections to have been photographed from D.H. aeroplanes, flying between 5,000 and 6,000 feet high. The prints so obtained have been dovetailed together in a mosaic. One completed section stretches eastward from the Bank. A number of separate prints have been employed to prepare this strip, pieced together so accurately that it is impossible to see where one ends and the other begins.

In making the complete map, which, when constructed, will be some 20 ft. square and will cover an area of approximately 300 miles, it will be necessary to employ three aeroplanes, each communicating with the others by means of the wireless telephone, and all manœuvring precisely together according to an agreed plan. The cameras used will be improved machines of an automatic kind, exposing plates at intervals of a few seconds, and the pilots of the three aeroplanes, maintaining formation three abreast as they cross and recross above the City, will so steer their machines that the sideway field of one camera overlaps slightly that of the one in the aeroplane flying next to it. In this way, flying to and fro on given lines, the three aeroplane will cover London in a series of broad bands. When all the photographs have been taken—and some sections may have to be photographed several times owing to the existence of low-lying clouds or mist—it will be a task of great delicacy and skill to piece together all the prints, which are expected to number about 10,000.

The completed section is very clear; a landmark such as the convergence of thoroughfares at the Bank, or the roof of a big station like Cannon Street, is seen at once. A tiny photograph of each separate building is obtained, while through a magnifiying glass can be seen minute pictures of the omnibuses and other vehicles in the streets.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, February 7 to 12.

COLOUR PHOTOGRAPHY.—No. 4,620 Colour photography. S. M. Procondine-Gorsky.

PRINTING.—No. 4,502. Photographic printing apparatus. R. N. Kerr and F. W. Tassell.

LENSES.—No. 4,541. Photographic lenses. Optische Anstalt C. P. Goerz Akt.-Ges

STEREOSCOPY.—No. 4,988. Means for imparting stereoscopic effect to photographic negatives, prints and projections. F. G. and J. McKim and H. Newbold.

PASSE-PARTOUT FRAMES.—No 4,756. Passe-partout frames for photographs. H. C. F. Waghorn

CINEMATOGRAPHY.—No. 4,543 Cinematographic apparatus. Carey-Gavey Syndicate, Ltd., and K. Higginson.

CINEMATOGRAPHY.—No. 4,489. Moving-picture projection apparatus. J. M. Carruthers and A. E. Cox.

CINEMATOGRAPHY.—No. 4,503. Cinematograph machines. J. A. Cockett.

CINEMATOGRAPHY.—No 4,367 Shutters for cinematograph projecting apparatus. E. A. W. Gates and J. Goldberg.

COLOUR CINEMATOGRAPHY.—No. 4,437. Method for producing cinematograph pictures in natural colours R. Killick and H. Stewart.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

THREE-LENS ANASTIGMATS.—No. 157,037 (July 13, 1920). The invention relates to a lens of the Cooke type, i.e., a lens which consists of three members separated by air spaces, the middle member being a simple negative or divergent lens, and the front and back members, both being simple positive or convergent lenses.

The object of the invention is to provide a cheaper construction of such lenses without sacrifice of quality. This is achieved by the use of a glass of low refractive index for one of the positive lenses in a particular and novel combination of constructional elements.

Throughout this specification the term "positive lens" is used to describe a convergent lens, and the term "negative lens" to describe a divergent lens.

The terms "focal length" and "power" referring to a simple lens are used in the usual approximate sense defined by the equations :—

$$\text{Power} = \frac{1}{\text{focal length}} = (n_D - 1)\left(\frac{1}{r_1} - \frac{1}{r_2}\right)$$

where r_1 and r_2 are the radii of curvature of the first and second surfaces of the lens and n_D the refractive index of the material; that is to say, in assessing the two quantities, power and focal length, of an element of the construction, the convention of ignoring the thickness of the element is adopted.

It is found that good definition over an angular field 60 degrees in extent can be obtained from a three separate component lens using shallow curves under the following conditions :—

1. The refractive index for sodium light of the glass of the negative lens is to lie substantially between the limits 1.542 and 1.576.

2. The negative lens must be unsymmetrically double concave; it must present its face of deeper curvature (*i.e.*, shorter radius) towards the incident light, and must have a focal length substantially less than 30 per cent. of the equivalent focal length of the combination

3. The positive lenses must be decidedly different from one another in focal length in order to secure a short overall length of the combination. It is found that the best results require that the focal length of the weaker positive (front) lens should differ from the equivalent focal length of the combination by not more than 18 per cent.

4. The refractive index for sodium light of the glass of the stronger positive (back) lens should be not less than 1.57.

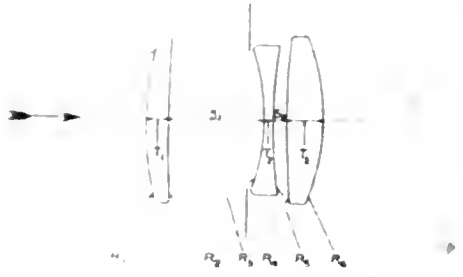
5. The stronger positive lens must be unsymmetrically double convex; it must lie behind the negative lens viewed from the direction of the incident light, and must present its face of longer radius towards the negative lens. The air space separating the stronger positive lens from the negative must not exceed 2½ per cent. of the equivalent local length of the combination, and it must have the shape of a positive meniscus lens.

6. The weaker positive lens must be of boldly pronounced meniscus shape, its concave side having a radius of curvature, which is not greater than twice the equivalent focal length of the combination. It must have a refractive index less than 1.535. It must present its convex side towards the incident light, and its concave side towards the negative; and it must lie in front of the negative lens as viewed from the direction of the incident light. The air space separating the weaker positive lens from the negative must be substantially greater than 5 per cent. of the equivalent focal length of the combination, and it must have the shape of a double convex lens. Reference is made to the following specifications :—Nos. 22,157 of 1910, 3,399 of 1911, and 6,328 of 1913.

A numerical example of the improved construction will now be described :—

The radii of the successive surfaces are numbered R_1, R_2 and so on, counting from the front as shown in the figure.

The sign convention adopted here is the + attached to a



radius means that the corresponding surface is convex towards the incident light, and − attached to it means that it is concave towards the incident light.

The glasses are specified by the refractive index for sodium light, n_D, and the nu value.

The thicknesses of the three lenses are denoted by T_1, T_2 and T_3 and the air spaces by S_1 and S_2 as shown in fig. 1.

All the linear dimensions are in inches.

Equivalent focal length, 10 in			n_D
$R_1 + 3.862$	T_1 .177		1.5149
$R_2 + 13.74$	S_1 .75		
$R_3 - 1.699$	T_2 .066		1.5531
$R_4 + 4.044$	S_2 .110		
$R_5 + 7.170$	T_3 .290		1.6168
$R_6 - 1.768$			

Diaphragm to be .15 in front of the vertex of R_3.

Power of strongest lens (the negative).

$$.5534 \left(\frac{1}{1.699} - \frac{1}{4.044}\right)$$

$$= .0625$$

Focal length 2.162 21.6 per cent. of focal length of combination.

Power of weaker positive lens (the front)

$$.5149 \left(\frac{1}{3.862} - \frac{1}{13.74}\right)$$

$$= .0958$$

Focal length = 10.44 = 4.4 per cent. different from focal length of combination.

Relative aperture f/7.7.

nn-value	Type Nos. of glass in Chance's catalogue
58.0	1066
46.1	7983
59.0	4873

It is seen that the deepest curve in this example of the construction is of radius 1.699 in. The corresponding curve of the Cooke series V lens of the same relative aperture $f/7.7$ described in specification No. 15,107 of 1895, is of radius 1.327 in. As the diameters are the same, it is seen that substantially shallower curves are used, and that therefore the new combination is cheaper for manufacturing purposes.—Taylor, Taylor and Hobson, Ltd., and Arthur Warmisham, Stoughton Street Works, Leicester.

The following complete specifications are open to public inspection before acceptance:—

COLOUR PHOTOGRAPHY.—No. 158,511. Colour photography. A. Keller-Dorian.

REPRODUCTION METHOD.—No. 158,552. Photographic method for the pictorial reproduction of a solid. L. Lumière.

PLATE-HOLDERS.—No. 158,514. Plate-holders for taking Röntgen photographs. G. Bucky.

CINEMATOOGRAPHY.—No. 158,526. Cinematograph projection apparatus. Petra Akt.-Ges. für Elektromechanik.

CINEMATOGRAPHY.—No. 158,529. Process for renovating cinematographic films. A. Meissner.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, February 22, the president, Dr. G. H. Rodman, in the chair.

Mr. D. Charles read a paper on "Improvements in Flashlight," illustrated by flash lamps of his design embodying different systems of ignition. He laid special stress upon the importance of a method of ignition which was certain in its action, could be operated in an instant, and did not call attention to itself. Since flashlight was largely used for living subjects, it was very disadvantageous that the sitter should be aware that the flash was about to be fired; his knowledge caused a strained expression. Mr. Charles showed first a pattern of igniter in which a small steel pin is kept red hot in a Bunsen flame, and is pulled forward to enter the pile of flash powder contained in the pan.

Turning to methods of ignition by percussion caps, he said that the essentials for their efficient use were the employment of a holder for the cap by which the hammer, which fired it, could be brought on to it with great accuracy, and, secondly, the delivery of a sharp blow. A wax vesta served as well as a cap. Mr. Charles likewise showed a method of firing a flash by a high-tension electric spark operated by a self-contained battery and coil. This system was the only one he knew for satisfactory firing of a number of flashes at the same moment.

Mr. Charles devoted special attention to the spread of the flash by means of a suitable shape of flash pan. If flash powder were fired in an open pan, like a saucer, the flame of the powder moved in all directions, so that there was a large area which produced illumination in a vertical upward direction, and was useless. By making the pan in the shape of a trough with somewhat high sides relatively to the width, the flash was spread out into a sheet which, with a small charge of powder, would be, say, 30 x 20 inches in size, and with a large charge of as great an area as 5 x 3 feet. For measuring the powder he had designed a small device consisting of two thin metal discs of unequal sizes fixed to each end of a rod of about 3 inches length. The larger disc, when dipped into the powder took up twice as much as the smaller; and he had drawn up a table of powder quantities required for various subjects according to the working F number of the lens and the distance of the subject from the flash. He showed a number of lantern-slides of difficult subjects taken by flashlight, which exhibited the qualities of soft shadows and detail in the shadows characteristic of daylight work.

In the discussion, Mr. Walter Thomas strongly advocated the use of a diffuser in front of the flash, as, for example, the folding flash bags. He very strongly emphasised the degree to which photographers in America and other countries were in advance of those here in the use of flashlight, which possessed immense possibilities for home portraiture.

Mr. Warburg said that if the flash was spread to a large area by the pan, as shown by Mr. Charles, it was not necessary to use a diffuser. He inquired if the strong light of a flash was found to

cause any injury to the retina of the eye, as was found to be the case with some of the extremely powerful arc lamps now used in cinema producing studios.

Mr. Wratten thought that flashlight had been in use for a sufficient number of years for any cases of injury to the eyes to have arisen, but he had never heard of one.

Mr. K. Hickman urged that flashlight photographers instead of regarding the smoke as an evil should consider it a blessing, inasmuch as the major portion of the illuminating effect of the flash was produced, not from the flame of the burning material but by light (from a small flame) reflected from the smoke produced from powder burnt at an earlier moment of the explosion.

Mr. Banfield, from a long experience of methods of firing flash powder, said that the only certain method was with a piece of "quicklight," or with a spark from a disc of pyrophorous metal. In the past he had used with perfect satisfaction a series of Abel fuses for simultaneous ignition of a number of flashes, but the fuses were no longer obtainable.

Mr. Charles, in his replies, referred particularly to photographs he had taken, which made it perfectly clear that the light was produced by the flame and not by illumination of the smoke. His objection to many methods of ignition was that they were not instantaneous; even the sparking disc gave a burring sound before the flash was ignited.

On the proposition of the Chairman a most hearty vote of thanks was accorded to the lecturer.

CROYDON CAMERA CLUB.

Mr. R. H. Lawton, F.R.P.S., demonstrated "Enlarged Negative Making." An expert worker, he has also the knack of combining instruction with amusement, though to the pure heart, unsoiled with fake, he is yet another glaring example of pictorial lawlessness.

At the present price of dry plates expansive ideas can hardly be expected to be popular, and to meet the case last week he confined himself to enlarged negatives on paper.

His method of making enlarged negatives on dry-plates (briefly alluded to by him) is to start with a bromide enlargement. This is worked on with pencil, blacklead, and stump, and modified, if necessary, in many directions, even to the introduction of figures and other accessories. It is then copied in the camera, and as a matter of course a medal in due course follows, provided the judges know their business. He claims that no loss of quality arises, and judging from the results he has shown in the past this procedure has many strong points for much pictorial work. It also presents the advantage that more alterations and additions are possible on a large print than on a small transparency.

Naturally a certain amount of granularity may be anticipated, but correct illumination of the copy reduces this to a minimum, and any slight diffusing device practically eliminates grain.

The cheaper alternative of making a contact transparency, and from that an enlarged negative on bromide paper, was carried through by him with complete success. The dry-plate transparency is obtained by exposing to a candle-flame at the distance of 4 feet, which is determined by a piece of string. With all negatives identical exposures are given, and if perfect results do no materialise the string should be suspected. An inquiry by a member as to whether it was lengthened and shortened to meet the case of negatives of varying density, elicited the information that Mr. Lawton invariably produces negatives of constant high-light density required to be recorded in the transparency. "You are either a very clever worker, or something else," politely observed the questioner.

For the enlarged negative he had tried many bromide papers and most were satisfactory, particularly Wellington's single-weight "ordinary" surface. Exposure should be about three times that required for a print, and, all important, development should be pushed to the stage when action ceases, no matter if the image appears hopelessly buried. With a good, dense deposit there is no evidence of grain. For the transparency he employs Azol 1 in 32, and double this strength for the negative occasionally with a little bromide. The negative is susceptible to great control; parts may be rendered more translucent with canada balsam local reduction is feasible, and handwork easy.

It was unfortunate that the talented demonstrator had to catch a comparatively early train, for at the conclusion of his exposition little more than according a hearty vote of thanks for a really first-class evening was possible. The discussion, however, continued after he had left. Mr. Salt said that articles on paper negatives which appeared from time to time, might well lead a beginner to infer they were equal to dry-plate negatives. Granting this might be true for some work, it was equally true to say that a print of perfect photographic technique with a long range of gradation, such as might be seen in professional portrait and architectural studies, was never pulled from a bromide paper negative.

Mr. Harpur, who carries much weight, which occasionally invades his remarks, agreed. Paper negatives afforded a limited range of tones; if the picture fell within them, well and good, if not, nobody cared. The sloshy Bromoil splodger had a lot to answer for in his disregard of technique. "I am with you there," cordially endorsed Mr. Hibbert. Mr. President Keane (*genus splodger*) modestly alleged his pictures were always the products of perfect negatives, and urged Mr. Harpur to consider the matter in a more sanitary frame of mind. Mr. Purkis thought if a bromide print was wanted, a bromide paper negative should give a sufficient range of tones, a dictum affording no clue as to whether he spoke as scientist, technician or artist. Mr. Catharine pointed out that the range of tones might be sufficient, but a gentle range of gradation from one tone to another, in his opinion, was largely absent. Mr. Berry saw no reason why perfect technique and a long range of beautiful gradation should not run hand-in-hand with the highest artistic treatment, a remark to which no one could find reasonable objection.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square, W.C., on Friday, Febuary 11, 1921.

Present: Messrs. Marcus Adams, Alf. Ellis, A. B. Basil, Frank Brown, W. B. Chaplin, A. H. Chapman, Gordon Chase, Alex. Corbett, C. F. Dickinson, S. H. Fry, W. E. Gray, Reg. Haines, G. Hana, W. Illingworth, H. Lambert, R. N. Speaight, H. C. Spink, and F. G. Wakefield, and Lang Sims (Secretary).

Letters of apology for non-attendance were read from Messrs. F. Read, H. St. George, Swan Watson and H. Wheeler.

The minutes of the last meeting were read and confirmed.

Arising out of the minutes, Mr. Speaight said that on the matter of fees for Press reproduction, his agent had informed him that the new scale was working well, and he had never come across any case of refusal to pay the increases. In a few cases the new scale had been mixed up with that of the Press photographers, but these had been adjusted.

The report of the Finance Committee was adopted. It recommended payment of a few accounts amounting to the sum of £13 7s. 2d.

Mr. Speaight reported that there had been no meeting of the Congress Committee during the month, chiefly because he had been abroad. Mr. Marcus Adams had kindly offered to act as Secretary of the Exhibition part of the Congress. The question of securing a lecture from a Continental photographer had been considered.

The Secretary read letters which had been received from Mr. Abel, of *Abel's Photographic Weekly*, New York, and the National Photographic Association of America. Mr. Abel gave many interesting facts with regard to photographic conventions held in America, and mentioned names of the gentlemen who might be asked to address the British Congress. He suggested that the American and British Associations might exchange reports and portraits taken by their members.

Mr. Lambert thought these cordial letters, in which there were great possibilities, should not be allowed to lie on the table.

Some members referred to the announcement that Mr. Pirie McDonald was coming to Edinburgh in June, and suggested that he might possibly come earlier. It was agreed to await a further recommendation from Mr. Abel on the matter.

Mr. Adams submitted the report of the Exhibition Committee, which stated that the entrance fee was raised from 3s. 6d. to 5s.

The Committee had decided to send the entrance form to all members of the Association in order to make the Exhibition known as widely as possible to those engaged in technical photography as well as in portraiture. It was decided to ask the Council for a grant not exceeding £60, as last year. Arrangements had been made for a wide passage beyond the exhibition room to be used as part of the exhibition. With regard to the letter from Mr. Abel, it was hoped to do something in the way of exchanging prints.

The Finance Committee having reported its agreement as to the grant, the report of the Exhibition Committee was adopted without further discussion.

Mr. Hana reported that the question of the new "Circular" had been carefully considered. It had been unanimously decided by the Committee, to which this matter was referred, that advertisements should be accepted. It was agreed also that the title of the new paper should be "The P.P.A. Record." The cost of printing, etc., had been gone into, but no detailed statement was yet ready, and expert judgment was needed. Advertisers had not yet been approached, but it was generally felt that it would be a valuable advertising medium.

It was agreed that the matter should be left in the hands of Mr. Hana and his committee.

Mr. Hana said, in reply to a member, that it was not proposed that the periodical should be sold, but that it should be given as part of the value of membership. In answer to further questions, he said that it was hoped that, including the editorial expenses, the journal would be made self-supporting. It was agreed to defer further discussion until the more detailed scheme was received.

The Secretary read the draft of the annual report, and on the motion of Mr. Frank Brown, the Secretary was heartily congratulated upon his report, which it was agreed should be duly published.

Mr. Fry, in submitting the balance-sheet, said that the accounts had been duly audited. He called attention to the fact that the number of subscriptions, totalling 1,073, was greater than ever before. The amount received from that source was £497 15s., to which was to be added £26 for subscriptions that had been paid in advance. Commissions on insurance amounted to £20 10s. 3d. —a larger sum than had ever been received—and dividends and bank interest to £42 10s. 10d., also the largest amount ever received. The total amount received in connection with the Congress was £242 3s., and the expenditure was £198, so that the Congress paid its way. It was felt that the money spent in reporting the minutes of the Council meeting was well expended, the work being accurately performed. The four issues of the "P.P.A. Circular" cost £132, a little more than the Council thought it would be, owing to the higher cost of printing, etc. Mr. Fry added that it was exceedingly gratifying to be able to report a balance on the right side of £132 4s. 9d. They also had £475 in War Loan, £100 in National War Bonds, £300 on deposit at the bank, and £90 on current account, making a total of £965 as their actual liquid assets. This was not very far short of the £1,000 he had hoped for.

The financial statement was received with loud applause, and on the motion of Mr. Frank Brown a formal vote of appreciation and congratulation to Mr. Fry was accorded.

The Chairman said that he had been looking over the Rules, and found that several slight alterations were required.

In Rule 6 he suggested that the words "shall be held on the second Friday in October and January, and the Council may call extra meetings when it is thought desirable" should be deleted.

In Rule 7 the word "honorary" should be deleted.

In Rule 12, which was more important, the first part should read as follows:—

"That at every annual general meeting of the Association the President and four London and four country members who have served three years on the Council since their last election shall retire from office. The retiring members shall be eligible for re-election. Any member of the Association, by letter sent to the Secretary not later than the second Friday in January, may nominate a President and not more than eight members of Council."

By this means the Council would be saved the trouble of nominating a President and 24 members of the Council every year.

The suggested alterations were approved as a recommendation of the Council, to be moved by the Chairman at the annual meeting.

Mr. Fry thought it would be advisable to have a new rule giving the Council power to co-opt a member, instead of being limited to 24 members.

The Secretary reported that applications for membership during the month numbered ten, and all were approved.

Mr. Fry suggested that the Council should consider the desirability of circularising every photographer in the country for the purpose of making known the Association's aims, and securing new members.

The Secretary reported that an American in Ohio, Mr. Walter G. Keller, had written asking if he was eligible for membership. He had replied, sending him an application form, and saying that they would be only too pleased to receive him.

He also reported the receipt of a letter from a member asking for advice in regard to an alleged breach of faith concerning the use of negatives for the purposes other than those stipulated for where no extension of use had been provided for. Having considered the correspondence concerning the transaction in question, the Council agreed that the applicant should be advised that in their opinion he had no claim.

The Secretary reported that he had been nominated for the Council of the Royal Photographic Society, and that he would be glad of votes.

Mr. Basil remarked that he hoped those members of the Association who were also members of the Royal Photographic Society would use their influence to secure Mr. Lang Sim's return.

The Secretary mentioned the interesting correspondence on key industries in the "British Journal of Photography"; it was agreed that discussion on this matter should be deferred.

Mr. Wakefield raised the question of the definition of "technical" photography for exhibition purposes. Several members pointed out that this might include machinery, etc. Mr. Adams gave the definition: Anything but portraiture.

The next meeting of the Council will be held on March 11.

News and Notes.

CASCADE WASHERS.—In reference to our paragraph last week, Messrs. David Allan, Whitfield Works, 107, Mansfield Road, Kingsland Road, London, E.2, call our attention to the fact that they have been making these washers for some time past, and have recently put on the market all sizes, from ¼-plate to 15 by 12. Larger sizes are made specially to order.

PORTRAIT MOUNTS.—Messrs. Houghtons, Ltd., send us one of the sets of mounts illustrating their manufacture of these requisites, which they are offering to professional photographers for 2s. 6d. The mounts are nearly all of them of the ever-popular folder pattern, and are, without exception, most tasteful examples of the mount-maker's art. We are glad to notice the refined sense of what is needed in a photographic mount. Mount-makers have been a long time in getting rid of unnecessary and disturbing embellishments, but now it seems impossible that there can be anything in better taste or with a more appropriate quiet degree of decoration than the examples before us. The materials themselves are a pleasure to the eye—mounting boards and papers of agreeable texture and in soft tints of brown and grey. The set includes also a fair proportion of white mounts admirably suited to various styles and sizes of sketch portrait. We are quite sure that the photographer who examines one of these sets will find in it styles which he will be glad to adopt with advantage to his own productions.

BRITISH INDUSTRIES FAIR.—The London Fair, organised by the Department of Overseas Trade, is held this year at the White City, Shepherd's Bush, London, W.12, and includes seven large groups of trades. Photographic exhibits are included chiefly in division 4, which has its place right and left of the main entrance to the Fair in Wood Lane. Cameras and other photographic apparatus are represented by the exhibits of Messrs. Houghtons, Ltd., W. Butcher

and Sons, Ltd., Thornton-Pickard Manufacturing Co., Ltd., and Holmes Bros. (London), Ltd. Only one lens maker is an exhibitor, namely, Messrs. J. H. Dallmeyer, Ltd. The photo-material trade is, however, represented by several leading firms, namely, Messrs. Kosmos, Ltd., Leto Photo Materials Co., Ltd., and Wellington and Ward. Messrs. Johnsons show a full range of their manufactures in developers and other photographic chemicals, and Messrs. E. B. Fry, Ltd., have a stand containing their many specialities for passe-partout framing, lantern-slides, etc. According to the plan of the Fair, mounts and albums and frames are placed in other divisions. Mounts are shown by Messrs. Bartons', of Birmingham, Messrs William Johnson and Sons, and Messrs. D. A. Lowthime and Co., while frames for photographs of all descriptions form the exhibit of Messrs. Marion and Foulger, Ltd. A whole day can easily be spent making a tour of the many avenues of stands in the exhibition, which is a triumph of organisation, so positive a trimmph, in fact, that it is not easy to ascribe its existence to a Government Department. But then the Department of Overseas Trade has a way of its own.

Eastman Kodak Co.—A copy of the "Rochester Times-Union," of February 1, contains more detailed particulars of the judgment by the Federal Court of Buffalo on that day in reference to the protracted dispute between the Eastman Kodak Co. and the United States Government, under the Sherman Anti-Trust Act. The particulars contained in the Rochester newspaper correct those telegraphed to "The Times," which we quoted in our issue of February 18 last, p. 102. It is now reported the judgment directs the Eastman Kodak Co. "to sell and dispose of certain factories and certain lines of photographic goods." These factories and lines represent a total investment of approximately $3,786,000.

According to the decree the following are to be disposed of: Premo factory, South Street, Rochester; Century and Folmer and Schwing Divisions, Caledonia Avenue, Rochester; together with every line of cameras and accessories now manufactured in these plants.

Artura brand of photographic paper; Seed, Stanley and Standard brand of photographic dry plates, which are to be offered either with or without the so-called Aristo plant.

Judge Hazel decrees that the dissolution must take place within two years, under governmental supervision and to independent parties. The formulæ must be given to the purchasers who will get exclusive rights to them. If the sale of the above mentioned factories and lines is not made by the Eastman company within two years they will be sold at public auction.

In the decree no reference is made to the film business. This film business was developed by the Eastman Co. and control of it is not held to be the result of a combination of competing companies.

It is stated that the price of ordinary share capital in the Eastman Kodak Co., advanced more than 100 points in the stock market within the ten days preceding the delivery of the judgment.

Correspondence.

***Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*** We do not undertake responsibility for the opinions expressed by our correspondents.*

MATT GROUND PLATES.

To the Editors.

Gentlemen,—In your issue of January 4, p. 70, we have noticed the inquiry of M. H. Green in respect to matt plates. We should like to ask M. Green if he refers to transparency or negative plates. If to the former, we may be allowed to inform him that we have manufactured these plates for many years, and shall be happy to let him have samples of them. If to negative plates, we are willing to make these latter if M. Green would kindly supply particulars of the qualities which he requires.—Yours faithfully,

Griesbaser Freres et Cie.

27, Rue du 4 Septembre, Paris.

FACTORIAL DEVELOPMENT.

To the Editors.

Gentlemen,—It is with mixed feelings that I accede to Mr. Watkins' request for information as to my use of the factorial system published in last week's B.J. I should have published my factors before but for two reasons, first, they have been adopted from lists already published; and, secondly, I cannot let the figures stand alone, but must add some remarks, which I greatly fear will bring down reprisals on my head. However, a request from Mr. Watkins, to whom I, in common with every photographer, am so much indebted, must not be left unanswered from any motives of self-defence. My factors are as follows:—

Pyro soda.	2 gr. pyro per oz. No bromide	10
.. ..	2 gr. pyro per oz. ½ gr. bromide	5
Azol	.....	25
Metol	.....	35

These are for normal negatives. I make the following variations for negatives hard or soft, according to the printing process to be used:—

	Normal for Illingworth De Luxe	Soft for Kodak Velvet Br.	Hard for Carbon Tissue.
Factor ..	5	4½	6

These different factors I found essential if the best results were wanted without after-treatment of negatives. They may seem greater variations than are called for by the different scales of the paper, but all I can say is that they were worked out and tested in the light of a great number of experiments. I should like to remark in passing that any attempt to produce ideal negatives without a definite idea as to what paper they are to be printed on is bound to fail.

Now as to subject and lighting. The following is a fair indication of my system, but it will not necessarily suit the work of any other studio:—

Lighting factors.	45 deg. light.	Sketch.	Line.
Standard, 5 .	5	4½	5½
Scale factors.	Head and shoulders.	Big head.	Full length.
Standard, 5 ..	5	4½	5½

These different factors must be co-ordinated. A factor which is the mean of paper, lighting, and scale factors must be used in each case. This sounds horribly complicated, but it is not so at all. After a week or two the figure required will be obvious at first glance. There is no need to make a note of the factor for each plate, as the total time need not be decided on until the subject is clearly seen on the plate.

I am afraid I stand a very good chance of being scalped by some of those lucky people who find one factor suit all work, because I shall be accused of making the system too complicated. I really cannot help it, the fault, if fault it is, obviously lies in the lighting. That is to say, the ratio of light to shadow is proportionately higher in my sketch lighting than in my line lighting, when allowance had been made for the variation in scale required in the prints. I did try at one time to equalise this, so that a "universal" factor might be used, but found it far more satisfactory to revert to variable factors. I should like to go into this more thoroughly, but unfortunately have no opportunity of studio work at present.

These figures fitted my own work very well indeed, but it is long odds against their being suited to anyone else. That is one reason why I have never published factors: a rough guide has been published for almost every developer, and I feel sure that personal trial is the only satisfactory way of finding what suits your own work. Mr. Watkin's system is, in my view, ideal, but it must be adjusted for each particular case if the best results are wanted.

Mr. Watkins is despondent about the apathy of the profession to technical matters, and with good reason. But can it be wondered at? I know no trade or profession where technical knowledge is worth so little in the labour market. Speaking as an assistant, I have never found technical knowledge a help in obtaining a post, or a path to a higher salary when engaged. Nor have

I ever found the slightest encouragement to continue such study, except from the added pleasure in my work.

With apologies for the length of this letter.—Yours faithfully,

Alton, Hants., February 19 ARTHUR G. WILLIS.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

B.A.—Impossible to say with certainty, but the negative has the appearance of having been developed with pyro-metol, a very generally used formula of which is that of the Imperial Dry Plate Company, contained in their Handbook.

D. E.—We should think your specimen is a bromide or gaslight print toned with Schlippe's salt; that is, the print is bleached in the ordinary mixture of bromide and ferricyanide, and toned in a bath of Schlippe's salt with small addition of ammonia.

E. E.—This kind of stain does sometimes arise with the chromium intensifier. We don't think the cause of it is properly known, but sometimes it is undoubtedly produced by exposure of the negative to too strong light between bleaching and re-developing.

A. G.—In the trade lantern-slides are most usually coloured with oil colours, but both water colours and dyes are used. About the only book which deals with the subject is "Colouring Prints and Lantern Slides," by R. Penlake, published by Messrs. Iliffe, 20, Tudor Street, London, E.C.4, price 1s. 6d., postage 3d.

A. E.—We have tried to turn up price of Euryscope lens, but the nearest thing we can find is a 25-in. lens listed for 30 × 20 plates in the 1887 Almanac. It is priced at £52 5s., so it is quite likely that a 30-in. lens would be £70 or more. The worst of this lens from the sale point of view is that its focus is longer than most people care about, and its aperture, which probably is not faster than *f*/6, is much too small for present-day ideas.

J. E.—(1) Impracticable to put a 12 × 10 extension box on the back of a half-plate camera, and then a repeating back on the rear of this extension. A light half-plate camera, such as you have, won't stand it. You had far better get a secondhand heavy pattern camera of 12 × 10 size, and have the repeating back fitted to that. (2) The negatives are largely printed on one of the printing boxes or by means of the strip printers, one model of which is the "Pawl," of Houghtons.

C. J.—We cannot identify any recent or special process from your description, which appears to apply to ordinary direct photo-lithography. We suggest that the text-book "Photo-Mechanical Processes," by W. T. Wilkinson, published by Messrs. Hampton & Son, Cursitor Street, London, E.C.4, will give you the necessary information on the working of the ordinary litho process, if such is what you are seeking. If it is something else, we are afraid we should want more definite particulars.

A. and Co.—It is quite clear from the reply of the Home Secretary, which was made to questions addressed to him by the P.P.A. some years ago, that under the Shops Act a photographer can carry out portraiture—which was the subject of arrangement beforehand—even at his own studio during hours when, under the Act, it requires to be closed. Therefore, there is no reason whatever for thinking that the taking of portraits at a place away from the studio could be a breach of the regulations contained in the Shops Act.

S. H.—Really we think the best advice we can give you is that you should study a good elementary book on photography, such as "Photography Made Easy," by Child Bayley. The flat, hazy result may be due to exposure, or development, or both (probably both). If we were you we should use quite a slow plate, such as an Ilford "Ordinary," or Imperial "Sovereign," and any ordinary developer, such as pyro-soda or M.Q. If there is a great deal of haze from the state of the atmosphere and you want a clear, bright photograph, then the best thing you can do is to use a Wratten process panchromatic, which is a rather slow plate, with a suitable filter.

W. H.—We are afraid that with the arrangement you propose your exposures will be rather too long for ordinary sitters. On the authority of the General Electric Co. we have it that 90 per cent. of the light is lost by indirect, or reflected, lighting. The arrangement of the lamps should be satisfactory, but to shorten exposures we should recommend a small diffuser in front of each lamp—say a 12-in. hoop covered with tracing cloth, using the reflected light as well. It would be necessary to hang a white reflector—say 3 or 4 ft. square—above the front lamp, as the sloping roof would waste much light. For the walls, we should recommend a light grey, and you will do well to get one of the ready-made distempers instead of trying to make your own. Oppsite the side lamp the wall would, of course, be white. A 1,000-candle-power will be most suitable for the top light.

M. D.—(1) About the most reliable type of shutter, and quite fast enough for the majority of work, is the roller blind, such as that of the Thornton-Pickard Co., Altrincham, Cheshire. (2) Of course your exposures must be correct, otherwise no system of development will help you to get uniform negatives. If this is so there is really nothing to choose between developing in a dish or in a tank. (3) You can get the supplementary lenses from opticians, such as Messrs. Sharland, 9, Thavies Inn, London, E.C.1, stating what focal length you require. The object of the lenses is to reduce the focal length of the main lens. The Petzval objective could be used for this latter, but owing to its size would need large supplementary lenses, larger, we think, than can be bought. The best lens for the enlarger described is an ordinary R.R. (4) Acetylene is not an easy light to fix to a vertical enlarger; the best is an inverted incandescent gas. If you have not gas and cannot arrange for daylight to be used in conjunction with the enlarger, then you will have to rig up some kind of a reflector above the negative, say, a sheet of white card, at an angle of about 45 deg., and illuminate this strongly with your acetylene burners. The firm for this latter is R. J. Moss and Sons, 98, Snow Hill, Birmingham. We have no experience of adding hydrogen peroxide to the water in the generator. We should doubt if it is much good, and it is quite likely it may be dangerous.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3174. Vol. LXVIII. FRIDAY, MARCH 4, 1921. Price Fourpence.

Contents.

SUMMARY.

Professor G. H. Bryan, F.R.S., in a contributed note, describes his experience of the usefulness of light-struck pieces of plates or bromide paper in testing the activity of a developer. (P. 123.)

MM. A. and L. Lumière and A. Seyewetz, in a paper on the action of the persulphate reducer, express their disagreement with some conclusions reached by other experimenters, and lay emphasis on the fact that regular reducing action of persulphate may be ensured by having the working solution of the required degree of acidity. (P. 124.)

In a contributed article, "Thermit" gives a formula for an amidol developer prepared to keep by means of glycollic acid. (P. 125.)

Mr. E. J. Wall calls attention to a paper of Carey Lea, published in the year 1875, on the action of the less refrangible rays on silver iodide and bromide, and gives an abstract of it in reference to recently observed phenomena in colour-sensitising. (P. 129.)

A recent patent specification, by F. W. Donisthorpe and Dye Impression Photos, Ltd., describes the process of treating a negative image for the production of dye prints therefrom by contact without action of light. (P. 127.)

A user of panchromatic along with other plates states his opinion of the chief disadvantages of the former, which require to be set against the superior results obtained. (P. 131.)

In a notice of the fine pictorial collection brought together at the Scottish Salon we signalise some of the notable exhibits of portrait and landscape work. (P. 123.)

In a leading article we endeavour to answer the questions:—When may a photographer legally copy a portrait photograph made at another studio and in what circumstances is it etiquette that he should do so? (P. 122.)

We regret to record the death in South Africa of Mr. A. H. Lisett, treasurer of the Royal Photographic Society. (P. 126.)

The advantages of a vertical pattern of enlarger as regards small working space and convenience of handling, are becoming more widely appreciated. (P. 122.)

In a reaction from the ornate background, there appears a tendency to employ dark grounds too closely approaching uniformity. (P. 121.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

A recent paper by Dr. R. S. Clay in "Penrose's Annual" outlines a method of producing colour photographs by means of a microscopically wedged film. (P. 9.)

A recently painted process relates to the production of two colour or three-colour cinematograph projections from which, so it is claimed, colour fringing is eliminated. (P. 10.)

Some hints on the exposure of Autochrome plates on interior subjects in dull weather are contributed by Mr. H. W. Canning Wright. (P. 12.)

EX CATHEDRA.

Dark Backgrounds. There is, and has been for some time past, a tendency to use a perfectly plain black background for portraiture, but a singular lack of depth is a feature of such pictures, and some photographers seem to be trying to remedy this by introducing weird splashes of light. As a matter of fact, a perfectly plain, unrelieved background is rarely found in nature, and as far as we know, apart from conventionalised or decorative pictures, no painter has ventured to use one for a portrait. It is not always safe to trust to the older painters for guidance in this direction, although graduated backgrounds are almost invariably found, because in many cases the darkening of the pigments and varnish has obscured the original work. We are convinced that many of those who have adopted the plain black style need only a hint to return to the use of a graduated background which will give the necessary impression of relief and distance. The best backgrounds are like the best people, those which do not obtrude themselves upon the beholder, and the highest praise that can be given to the setting of a portrait is that it serves its purpose without being in evidence. The quite plain background is no doubt a reaction, and a very healthy one, from the terrible things in the form of ducal palace interiors and Haddon Hall terraces, which at one time were the stock-in-trade of almost every studio. Nevertheless, it is true that unobtrusiveness can likewise be carried to an extreme, and that is a feature which marks much of the work which we see from modern studios.

* * *

Screen Testing. Since there are many light-filters, or, as most photographers call them, yellow screens, which have a different factor for different plates, the following practical, if unscientific, system of ascertaining the increase of exposure needed with any brand of plates may be of service to their owners. A large black and white print, platinotype or bromide is copied, first without the screen, giving an exposure which is judged to be correct. The filter is next fitted to the lens, and using the same brand of plate a strip test made by drawing out the slide entirely and closing it, an inch at a time, giving double the exposure at each step, a convenient series being 2 seconds, then 2 seconds, then 4, 8 and 16 seconds for each second the unscreened plate was exposed. We then have a series of exposures ranging from twice to thirty-two times that given without the screen, and this is usually enough. It may not always be realised that with most screens the ratio for exposures with daylight and the arc or mercury-vapour lamps differs greatly from that necessary with daylight. When the two negatives are finished it is easy to see which strip corresponds most closely with the unscreened negative, and to make a note of the factor, plate and illuminant. The two plates should, of course, be developed for exactly the same time.

A Vertical Enlarger. Photographers whose working space is limited are often at a loss to find a position where an enlarging apparatus can be kept ready for use without unduly encroaching upon the area available for dark-room work. When fresh apparatus has to be installed, a vertical enlarger meets the difficulty, the space occupied being little more than the size of the largest picture which is likely to be wanted. Those who already possess an enlarging lantern will be interested to know that it can be used vertically without in any way impairing its usefulness in its ordinary position. A drawing board or table is fixed in a corner of the dark room and two stout wooden grooved runners are screwed vertically to the wall or partition. A board or frame travels up and down in the grooves, and to this the base of the enlarger is fastened with thumb screws, the whole being counterbalanced by means of an ordinary sash-weight with cord and pulley. A small half-watt lamp is a convenient source of light, but an inverted incandescent mantle may be used, if the precaution be taken to interpose a piece of ground glass between it and the condenser. This not only obliterates the texture of the mantle but prevents any ash, dust or fragments of mantle from falling upon the condenser. Our correspondence shows that the vertical enlarger is being more generally appreciated at its due value by photographers, not only on account of its saving of space but for its facility of manipulation.

COPYING PORTRAITS BY OTHER PHOTOGRAPHERS.

THE question whether he should copy a photograph, taken by another photographer and brought to him for that purpose by a customer, is one which every photographer has to answer at some time or other—and some photographers have to answer it many times every week. The question presents itself in two aspects, the legal and the ethical. The former can soon be disposed of.

If the copyright in the photograph is not the property of the customer, or of some other person whose permission to have it copied has been obtained by the customer, then the photographer exposes himself to exactly the same risks of action for infringement as does the customer. The Copyright Act does not distinguish between copying a copyright work and causing it to be copied. It need hardly be explained to those who have even only a nodding acquaintance with the law of copyright that at the present time any photograph of comparatively recent origin is copyright; that is to say, the right to copy it belongs to somebody or other. It is only in the case of photographs of such age as to betray the ancient date of their origin that copyright has probably expired by lapse of time, or by transference of the negative without assignment of the copyright under the 1862 Act. Therefore, it is simply ordinary caution for a photographer to assume that the copyright belongs either to the customer or, if not to him, most usually to another photographer whose name may or may not appear on the mount. As a rule it is not safe to assume that the customer is clear or right in the view he takes as to the ownership of the copyright. Very often he displays his entire ignorance of the existence of such a legal property as copyright. A little inquiry, however, will often be sufficient to ascertain the circumstances in which the portrait was taken. Obviously, if the portrait was made as the result of the customer accepting an invitation to be photographed, the copyright in 99 cases out of 100 is not his at all, though very often he may not be aware that he has not the right to have it copied. Where this is the case, the photographer who is asked to make a copy may feel pretty certain that if he does so, and the fact becomes known to the studio which has the original negative, the copyist will be asked what he proposes to do about the infringement.

When we come to considerations of ethics or etiquette it is not by any means easy to formulate an answer which will apply in all circumstances. The question indeed raises a delicate problem—a problem which each photographer must solve for himself according to his own ideals and his own circumstances. However high a tone he may wish to take in his business relationships, he will not regard the problem as arising in connection with the copying of amateur photographs or old portraits taken by firms which are no longer in existence. No photographer would have the slightest compunction in undertaking copying orders of this kind. The question arises only when a photographer is asked to copy a portrait by a brother professional who could, if requested, supply additional prints from the original negative. The circumstances in which such an order may be given vary almost indefinitely, and the problem varies in difficulty accordingly.

There is the woman, for instance, who admires the artistic poses but dislikes the high charges of a rival, Mr. A, across the street. She gets him to finish half-a-dozen prints of one pose and then brings to Mr. B either one of these prints or a packet of untoned proofs and asks him to tone and copy them.

There is again the customer who is so pleased with the photograph which she had taken two or three years ago, that she prefers to have more prints of it rather than sit again, but for some reason or other does not wish to go back to the photographer who did the work originally. Or, perhaps, one of a photographer's own customers, whom he has often photographed, may ask him to copy a photograph which she has just had taken in London by one of the leading artistic portraitists from whom she has, for reasons of economy, ordered only half-a-dozen copies. Or perhaps he is asked by an old customer to copy a portrait which has just been received from a friend or relative in Australia or Canada.

It is clear that there is a wide difference between these cases. In the last case, ninety-nine out of a hundred photographers would probably take the order; in the first case, probably nine out of ten would refuse it. Each man must decide for himself just where he will draw the line, if indeed he wants to draw any line at all. Unfortunately, many people, especially women who have no experience of business, seem to take it as a matter of course that one photographer will have no objection at all to copying the work of a rival. It never occurs to them that either photographer could object—the first, because, whatever its artistic or technical merits may be, it is put out as the work of another; the second, because the fact that he is asked to supply copies involves the reflection that he himself is not competent to make as good a portrait.

Although the copying of photographs can prove a very profitable business, it is probable that the great majority of photographers would much prefer to make their own portraits rather than copy the work of another man. Many, indeed, resent being asked to copy another man's work, because they feel, rightly or wrongly, that they can do it as well or even better themselves. Naturally, the number of these men will increase with the rise in the status and skill of professional photographers. There is reason to hope, therefore, that in the near future it may become more and more easy for professionals to draw the line strictly and refuse more and more of these copying orders.

THE SCOTTISH SALON.

The promoters of the thirteenth Scottish National Salon are fortunate, on this their third visit to Dundee, in having secured the Victoria Art Galleries to accommodate their exhibition. Ample room is afforded to carry out a scheme of hanging which shows the pictures to the best advantage, and the carrying out of the condition which the committee made to have the prints either framed or in passe-partout, glass optional in both cases, has enhanced the appearance of the display and fully justified the innovation.

In all some 375 prints are on view, 275 of which are of Scottish production. Scots exhibitions are usually strong in landscape, and the present is no exception to the rule, but the subjects chosen for pictorial treatment are pleasantly varied and include portraits, seascapes, architecture and genre studies.

Prominent among exhibitors in landscape is Mr. Hector Murchison, who shows two fine subjects from the Scottish capital, "Salisbury Crag" (No. 11) and "The Crown of Scotland" (No. 80), the spire of St. Giles in the latter standing up in majestic splendour above the nicely subdued roof tops and chimney tops of the surrounding neighbourhood. J. M. Whitehead is again prominent with his low tone subjects, his "Craigmillar" (No. 223) in transferotype, a new medium for him, perhaps being the finest of three exhibits. W. C. S. Farguson is strong with some of his delightful rock and spray studies, but "A Winter Calm" (No. 40), a snowscape of fine quality, serves to show his versatility.

William Howat has also a fine Bromoil of snow in "Sunshine and Snow" (No. 48), and Dan Dunlop shows two characteristic harbour scenes in "Pittenweem" (No. 13) and "A French Harbour" (No. 21), and is equally successful with other subjects.

W. S. Crocket's landscapes exhibit delightful spaciousness in "Morning on the Hillside" (No. 52) and "The Hilltop" (No. 65); the contrasts and lines of the latter are highly decorative. R. D. Stewart, London, shows some woodlands in Hampstead Heath (Nos. 134 and 157).

There are many fine examples of portraiture of distinction, different styles from the vigorous work of Robert Chalmers, of Sunderland—whose "Lucretia" (No. 26), a girl with bare shoulders, is full of grace—to the delicacy of William W. Weir's charming child studies, a fine example of which is "Laughing Eyes" (No. 212). Robert Marshall's "Portrait Study" (No. 109) of a mother and child is delightful in its simple, fresh spontaneity. Miss Jessie Thomson, Glasgow, is again very successful with some fine studies in platinum (Nos. 38, 39 and 42). The work of William Crooke, of Edinburgh, is also conspicuous, his "Sir Harold Stiles" (No. 238) being a particularly fine portrait of the famous surgeon. His portraits of Lord Scott Dickson (No. 77) and Sir John Lorne M'Leod (No. 70) are imposing works. Attention must also be drawn to Robert Crerar's "Don Cossack" (No. 107). Miss K. M. Alexander's "Ave Maria" (No. 58) is a fine study of the strong features of a nun.

James Slater's works are among the most delightful and characteristic in the exhibition, subtle in their refined quality. There are nine on the walls. "Sunlight after Rain" (No. 95) and "Silver Light with Quivering Glance" (No. 105) are instinct with the qualities which their titles imply. "My Lady's Garden" (No. 12), on the other hand, is in a low key, and just as magnificent in this kind of tonality.

T. Carlyle departs from his usual high key in shipping studies to present "A Pilot of the Night" (No. 252), a Bromoil of exceptional richness, whilst A. J. Wood, Aberdeen, shows a similar theme in "At the Close of Day when the Hamlet is Still" (No. 188). Right at the other end of the scale is Robert Ure's "Silent Harbour" (No. 68), which is full of delightful atmosphere, and the same effect has been caught by W. Duncan in "Light at Eventide" (No. 203).

A picture of outstanding merit is (No. 232) "A Tinker's Funeral" (burial would be more appropriate) by J. M. Dunn, Brechin, who faithfully depicts the reverence and grief of a little group of tinkers gathered round the last resting place of one of their number. A picture of real human interest. Flower studies (Nos. 34, 46, 228 and 234) find an able exponent in Wm. B. U. Patterson, of Dundee, whose prints in green carbon are masterpieces in technique; whilst local exhibits of merit are shown by H. C. Milne and V. C. Baird.

SOME SIMPLE DEVELOPMENT TESTS.

Now that "temperature" and "factorial" timing methods are to the fore, it may be useful to again call attention to the use of bromide paper strips for testing the speed of developers. My original note[1] on this subject elicited some valuable criticisms from Mr. Alfred Watkins, from which and from my subsequent experience it would appear that the numerical details involved in the use of such a method must be left to individual workers, and that a tabulated system of formulæ or factors would hardly be practicable.

The shavings which I obtain in trimming bromide papers to the exact size to fit my enlarging box furnish more than a sufficient supply of testing strips, which I keep packed away out of *continuous* light, which, however, freely falls on them when the package or box is open for a short time. To test the developer I dip the end of one of these strips into it, and watch the time which elapses before it is *completely* blackened up, making the test in full daylight. As a rule, I make several tests before developing, as the process is so easy. For tank development of plates (under conditions practicable in foreign hotels), I have obtained the desired contrast by multiplying the time of blackening of the test slip by 40, or more or less according to subject and required result.

1. "B.J.," Sept. 4, 1908, p. 677.

For developing bromide enlargements (from ¼ to 1/1 plate), I regulate the degree of dilution till the time of blackening of the test slip is 30-40 seconds, preferably 35 seconds, but this number is subject to individual variation. In my experience a speed of less than 25 seconds is liable to give blotchy prints, and one much exceeding 45 or 50 seconds involves risk of stains, fogging, or other evils. As a result of such experiences one of my boxes has been inscribed with a label, "Don't forget to Test the Developer!"

By this method account is taken, not only of temperature conditions, but also of any possible deterioration in the developer itself. A thermometer cannot discriminate between a freshly opened bottle of compressed tablets and one opened two years previously.

The manner in which the bromide test slip darkens up affords an indication of the effects of a restrainer, a slip began to turn dirty grey in 5 seconds in metol quinol, but did not blacken thoroughly for about 35 seconds. On adding potassium bromide another slip did not darken perceptibly for a long time, then it suddenly began to flash up, and was completely blackened in nearly the same time as before. With excessive restrainer the slips ultimately darkened to a dirty grey colour rather than a clean black.

Another useful testing stock is afforded by plates that have been rendered useless either by breakage or fogging, and which have been left undeveloped and unfixed. Such a waste plate may be cut or smashed into some hundreds of fragments. In my developing tank the plates are enclosed in an inner box, which is lowered into an outer trough containing the solution. My latest plan is to place a fragment of the fogged plate (or the broken one previously exposed to daylight) in the solution, which overflows at the top of the tank. This can be taken out from time to time and examined in broad daylight to see when the darkening effect has worked through to the glass side, and this affords an alternative indication of the time for removing the plates. This test is particularly useful, allowing as it does for any change of temperature that has taken place since the plates were first inserted. I have succeeded in further checking the result by a second test with a bromide slip in the later stages of the development.

But a still more important use of the chips of fogged plate is to place a small fragment in the fixing bath with a batch of bromide prints, leaving the latter in till the glass has cleared. A patented device on a similar principle was described some years ago (*vide e.g.*, "B.J." Almanac, 1915).

G. H. Bryan, F.R.S., Pres. Inst.Ae.E.

ON IRREGULARITIES IN THE ACTION OF THE PERSULPHATE REDUCER.

Since we first observed[1] the characteristic property of ammonium persulphate, in its action in a silver image, of acting first on the heaviest deposits, and since we first pointed out the usefulness of this property for the improvement of under-exposed and over-developed negatives, the reducer has been studied by many experimenters for the purpose of explaining its behaviour or of pointing out the irregularities met with in the use of different makes of ammonium persulphate.

In a notice of observations of this kind, Sheppard[2] reviews the different theories which have been proposed in explanation of the cause of the specific action of persulphate on the heaviest densities of a negative. He does not, however, quote the papers of ours from which later work originated. The following is the explanation we gave of the peculiar action of persulphate.

The persulphate oxidises the silver in the film, and the sulphuric acid which is liberated in the reaction dissolves the silver oxide formed, yielding silver sulphate or double sulphate of silver and ammonium. The first-named series of reactions may be represented by the equations:—

$$(NH_4)_2 S_2O_8 + Ag_2 + H_2O = (NH_4)_2 SO_4 + Ag_2O + H_2SO_4$$
$$Ag_2O + H_2SO_4 = Ag_2SO_4 + H_2O$$

It may equally be assumed that a double sulphate of ammonia and silver is formed according to the equation:—

$$(NH_4)_2S_2O_8 + Ag_2 = 2\,Ag\,NH_4SO_4$$

The soluble silver salt, which is thus in the presence of the excess of ammonium persulphate externally covering the image, tends to be reduced and to act as a physical intensifier[3] of the silver forming the surface of the image. Silver is thus deposited on the surface of the image, and this deposit interferes with the solvent action of the persulphate on the superficial parts of this image. On the other hand, since the underlying parts of the image are not exposed to an excess of persulphate, the silver dissolves unimpeded by the reduction of the silver sulphate formed.

According to the theory suggested by Marshall,[4] the formation of silver sulphate is a necessary condition for the solution of the silver, the absence of free silver ions bringing the reaction to a standstill. Whilst it must be admitted that this is a condition for the exercise of the solvent action of the persulphate and that an excess of soluble silver salt accelerates this action, it does not explain more satisfactorily than does our theory the selective action on the heavy portion of the image.

The same remark applies to the theory of Lüppo-Cramer quoted by Sheppard, in which the author states that the developed image is formed not of reduced silver but of a compound of silver and a photo-salt. Although the proportion of photo-salt is very small, it would be greater than would correspond to the least exposed portions in consequence of a less active reducing effect of the developer in these parts.

Reducers, such as Farmer's, which contain a solvent (hypo) of the photo-salt, would attack the lighter deposits more easily, whilst reducers which consist of a solvent of silver and not of the photo-salt would act in greater measure on the heavier deposits, which contain a lesser proportion of photo-salt.

Lüppo-Cramer seeks to support his hypothesis by the observation of S. C. Puddy[5] that the action of persulphate can be modified and caused to resemble surface reduction by addition of ammonium sulphocyanide.

Sheppard[6] disputes this action of ammonium sulphocyanide, regarding this compound as attacked by the persulphate with formation of hydrocyanic acid (prussic acid). He attributes the action of the persulphate upon the silver image to the presence in all commercial persulphate of small quantities of ferric salt, which acts as a catalyser, and, according to him, is the cause, through its varying amount as an impurity, of the differences exhibited by commercial persulphates. The action of the ferric sulphate on the silver image would produce the soluble silver salt necessary for auto-catalysis more rapidly, the resulting ferrous sulphate being immediately re-oxidised to the ferric state.

We have found with Sheppard that commercial samples of ammonium persulphate contain small quantities of ferric salt, as shown by a red coloration with potassium sulphocyanide, but this salt does not appear to us to be the cause of the greater or lesser activity of different persulphates, for we have found that every trace of iron can be removed from persulphate by repeated recrystallisations without depriving the product which has been purified in this way of its solvent properties, provided that its solution is of the required acidity.

A sample of sodium persulphate free from iron likewise behaved in the same way as ammonium persulphate in this respect.

We now come to consider the causes of the variation in the activity of ammonium persulphate. For the purpose of studying the causes which render persulphate of ammonia inactive and interfere with the production of regular results in the use of different commercial persulphates we have examined the action of substances which may be present in the solution, both those occurring as impurities in the persulphates and those arising from the water used in making the solution of the reducer.

We made tests first with distilled water and then with ordinary tap water.

1. "Bull Soc. Fr. Phot.," 1898, p. 395; 1899, pp. 226, 304; "B.J.," 1898, p. 473; "B.J.," 1899, p. 294.
2. "B.J.," 1918, p. 314; "Bull Soc. Fr. Phot.," 1919, p. 261.
3. Ammonium persulphate can act, like hydrogen peroxide, both as a chemical oxidising agent and reducing agent. It reduces the silver sulphate, as we have shown. Bull Soc. Fr. Phot.," 1899, p. 226; "B.J.," 1899, p. 294.

Tests with Distilled Water.

(a) *Effect of Acid.*—Using distilled water in dissolving the ammonium persulphate we found that in employing persulphate containing from 92 per cent. to 97 per cent. of the pure salt and of the same acidity, the reducing action of these different products is the same.

A sample of persulphate supplied as "neutral persulphate," and containing 0.22 per cent. of free sulphuric acid and 97.2 per cent. of the pure salt, behaved in practically the same way as a persulphate from the same source containing 0.49 per cent. of free sulphuric acid. Moreover, the acidity of a solution of persulphate gradually increases, owing to slow decomposition, according to the equation:—

$$(NH_4)_2S_2O_8 + H_2O = (NH_4)_2SO_4 + H_2SO_4 + O$$

The initial acidity of "neutral persulphate," which was 0.22 per cent. immediately after dissolving in water, rose to 0.93 per cent. after 24 hours and to 1.3 per cent. after 48 hours, at a temperature of 60 deg. F. Its solvent (reducing) action on silver became more rapid as the acidity increased. If the solution does not contain free acid, and more especially if it has an alkaline reaction, no solution of the silver takes place. But a neutral solution in water which is inert to start with becomes gradually active in proportion as decomposition of part of the persulphate renders the solution acid.

If the proportion of free acid in the solution is considerably increased the solvent action becomes much more rapid, and the persulphate no longer dissolves silver in the depth of the film but superficially, like other reducers, no doubt owing to the facts that the solution of the silver becomes the predominant reaction, and that the reduction of soluble silver salt which brings such solution of surface silver to a standstill no longer takes place in a very acid solution.

(b) *Effect of Chlorides, Bromides and Iodides.*—Stenger and Heller[7] have observed that the presence of small quantities of chlorides in the persulphate solution changes its mode of action, and they attribute this result to the fact that the soluble chloride precipitates as insoluble chloride the sulphate of silver which is formed, thus removing the catalysing silver ions and protecting the silver against acceleration of the reaction.

In studying the action of alkaline chlorides (of sodium, potassium, lithium and ammonium) on the persulphate reducer, we found that when the persulphate solution is feebly acid the alkaline chlorides when present in small quantity (0.01 sodium chloride per 100 c.c.s. 4 per cent. solution of persulphate) completely destroy the solvent action of the persulphate. By increasing the quantity of chloride (to 0.5 per cent.), the image gradually bleaches, being converted into silver chloride. The addition of sulphuric acid to this solution (2.5 c.c.s. of 10 per cent. sulphuric acid per 100 c.c.s. of solution) counteracts this chlorising effect; the image is not reduced, but, on the other hand, undergoes slight intensification owing to change of colour of the silver.

Bromides behave similarly to chlorides; in the case of iodides, iodine is liberated

The action of chlorides and bromides may be explained by the slow liberation of chlorine or bromine by the persulphate. The nascent chlorine or bromine tends to convert a silver image into silver chloride or silver bromide which is no longer attacked by the persulphate. Hydrochloric acid and hydrobromic acid, if present in the free state in the solution, behave similarly to chlorides and bromides.

(c) *Effect of Sulphates and Nitrates.*—Sulphates and nitrates of the alkaline metals, when present in small quantity, do not interfere with the action of the persulphate on the image, but if present in quantity as great as 0.5 per cent. the action on the silver image is retarded if at the same time the sulphuric acid in the solution is present in quantity between 0.45 per cent. and 1 per cent. of the persulphate. By increasing the acidity of the solution the silver is dissolved even in the presence of sulphates and nitrates.

(d) *Effect of Chemical Reducers.*—If the gelatine film of the negative contains reducing substances, e.g., hypo from the fixing bath which has not been completely washed out, it will be understood that the persulphate is thereby reduced and ceases to act as a solvent (photographic reducer) of the silver image in presence of sulphuric acid.

Tests with Ordinary Tap Water.

The various samples of commercial persulphate employed in the preceding tests made with distilled water were likewise used for a similar series of tests in which the persulphate was dissolved in ordinary tap water. The results obtained were similar in the two cases, but it must be mentioned that the tap water employed contained only an insignificant quantity of chloride and a small proportion of sulphates.

The results would certainly not have been the same had the water contained larger quantities of chlorides or sulphates.

The general conclusion from these results is that the cause of irregularities in the use of different commercial makes of persulphate is either that the persulphate is dissolved in ordinary water or in distilled water with insufficient addition of free sulphuric acid (in which case the reducer acts very slowly) or the solvent action of the persulphate on the silver image is brought to a standstill, particularly by the presence of chlorides or sulphates in sufficient quantity when using ordinary tap water for making up the solution.

In all these cases it is easy to obtain a normal reducing action with the different commercial makes of ammonium persulphate. For this, all that has to be done is to dissolve the sample in distilled water and to add as required solution of sulphuric acid so as to bring the acidity between 0.25 and 0.50 per cent. of the solution.

A. and L. Lumière.
A. Seyewetz.

GLYCOLLIC ACID AS A PRESERVATIVE FOR AMIDOL.

Amidol as a developer, though largely restricted to use on bromide papers, is decidedly popular among professionals. But every developer has its weak points and the fly in the amidol ointment is the marked instability of the diamidophenol salt. I have been a user of amidol for about fifteen years, and I have often tried to solve the stability problem by compounding some mixture that would keep, if not indefinitely, at least for some weeks. To describe all the mixtures that were tried (with varying degrees of success) would take too much time and space, but some recent trials of formulæ containing glycollic acid should interest users of amidol, although the results are not final or the experiments complete.

When I first decided to try glycollic acid—I had seen a mention of its peculiar property in the "B.J."—I set about finding out what proportion it should bear to the amidol and what formula gave the best deposit. My ultimate aim was, of course, to test the preserving power of the acid, but no amount of preservation is of value if accompanied by any degradation of quality in the resultant prints. My conclusions were that for development papers in general a solution containing—

Soda sulphite	5 ozs.
Amidol	200 to 240 grs.
Potass bromide	10 grs.
Glycollic acid	10 grs.
Water	75 to 80 ozs.

gave a deposit of a very fine shade of pure black. With Criterion papers a little extra bromide does no harm, and for Vitegas and Kodura an appreciable increase may be considered necessary, though the blacks on these papers with the above formula as it stands are very good.

Being satisfied that the above formula was good enough from the quality standpoint, I left a quart bottle of the solution standing for a week before putting it to use. When poured out it was in the dish for something like 2½ hours, during which 600 sq. in. of exposed paper passed through it, the last print showing no loss of quality. The next test I made was for quantity of work, and I found that a pint (which was three days old) was capable of developing 700 sq. in. (equivalent to about 32 post-cards), while 30 ozs. from another bottle did 1,060 sq. in. in the course of three hours. In the latter case, when the last print was through, the

developer—somewhat discoloured, but not muddy—was left in the dish for another hour, after which it was found to be still active.

Encouraged by the above results, I am now carrying out a series of methodical experiments to find out the maximum extent of preservative action exerted by glycollic acid, and the possibilities of compounding the two with other salts to obtain certain definite advantages. At the moment of writing I am optimistic, believing it quite practicable to improve the working qualities of amidol while reducing its cost, and also to compound new developers with well-known photographic chemicals.

The amidol used in the aforementioned formula was Johnsons'. This I have always found to be less alkaline—or more acid—than pre-war amidols. With the latter, which I believe are about again, the proportion of glycollic acid would probably be incorrect, as some action might take place between the acid and the alkali. Unfortunately, glycollic acid does not seem to be well known even among chemists. I had great difficulty in obtaining a sample, but I have heard that its manufacture on a large scale is a future possibility, as it has some commercial value. THERMIT.

ALFRED STIEGLITZ.

ALFRED STIEGLITZ was born at Hoboken. The date of his birth is not at the moment ascertainable. His reputation rests upon a long series of daring and often beautiful photogravures, printed in the only really sumptuous, truly *le luxe* periodical that photography has ever boasted—the "B.J. Almanac" not considered—to wit, "Camera Work."

The name of Stieglitz was a mighty one in Britain about twenty years ago; but with the course of time several things happened, amongst others, the war, and the name of Stieglitz became that of a forgotten thing. To all intents and purposes Stieglitz was dead.

But Stieglitz was a bad ghost to lay. He was dead, and is alive again; was lost and is found. His troubled spirit fretted for something, and broke away from the rest of the company of remorseful U.P. departeds. Like a boy who comes down in the night to steal one more tart, Stieglitz rose from the tomb to have one more one man show. His resurrection is a staggering phenomenon, and in its *eclat*, dazzling.

The fact is proclaimed by the silver trumpets and trembling harps of a 4 pp. circular, sumptuous in the old way. In this there is a self-psycho analytical report of all the "urges" and "complexes" of the *genus* Stieglitz. He has put on incorruptibility, and put it on thick:—"I was born in Hoboken. I am an American. Photography is my passion. The search for Truth my obsession." He asks us to note that in his "Statement" the following fast becoming "obsolete" terms do not appear: ART, SCIENCE, BEAUTY, RELIGION, every ISM, ABSTRACTION, FORM, PLASTICITY, OBJECTIVITY, SUBJECTIVITY, OLD MASTERS, MODERN ART, PSYCHOANALYSIS, ÆSTHETICS, PICTORIAL PHOTOGRAPHY, DEMOCRACY, CEZANNE, "291," PROHIBITION. The term TRUTH did creep in, but may be kicked out by anyone.

The rest of the proclamation is a catalogue from which we cull a bunch or two of these last-fruits; "Buildings Moving Northward," "Wall Closing In," "The Way Art Moves." These seem to show that Stieglitz has less use for still-life than ever.

"A WOMAN" (One portrait).
"HANDS" (One portrait).
"FEET" (One portrait).
"HANDS AND BREASTS" (One portrait)
"TORSOS" (One portrait).

What does this collection of human remains portend? Are they the *disjecta membra* of unsatisfactory sitters? The reiteration of the phrase "One Portrait" is perhaps a covert expression of disgust at multi-exposure and cinema work.

Apart from the æsthetic shambles we should much like to see this show, which dates from 1886 to 1921. What a *revue*! Its countless visitors will reel out from its portals dazed by the force of impressions received, and muttering, in a distracted search for a cause to fit effects so sublime, "He was born in Hoboken."

F. C. T

DEATH OF MR. A. H. LISETT.

WE regret to record the news of the death, at Port Elizabeth, of Mr. A. H. Lisett, honorary treasurer of the Royal Photographic Society and an active member of its Council. Mr. Lisett, in company with his daughter, left England in November last on a business trip to South Africa. At present only brief cabled intelligence of his death has been received. In addition to taking a large share in the management of the R.P.S., he had been for many years an active member of the North Middlesex Photographic Society, and was known for his lectures before these and other societies on popular photographic subjects.

FORTHCOMING EXHIBITIONS.

February 19 to March 12.—Scottish Salon, Dundee. Particulars from the Hon. Secretary, James Slater, Rosemount, Camphill Road, Broughty Ferry.

March 14 to 26.—Dennistoun Amateur Photographic Association. Hon. Secretary, Wm. F. Macpherson, 152, Craigpark, Dennistoun.

March 16 to 19.—Hackney Photographic Society. Particulars from the Hon. Secretary, Walter Selfe, 24, Pembury Road, Clapton, London, E.5.

April 13 to 23.—Portsmouth Camera Club. Latest date for entries March 31. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

April 15 to 23.—Professional Photographers' Association, at the Photographic Fair, Horticultural Hall, Westminster, S.W. Hon. Secretary, Marcus Adams, 83, White Knights Road, Earley, Reading.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Latest date for entries, March 17. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Latest date for entries, April 16. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, February 14 to 19:—

SHUTTERS.—No. 5,409. Releasing-device for photographic obturating slides. H. Klapprott.

DEVELOPMENT.—No. 5,097. Developing-tanks. W. A. Leggett.

STEREOSCOPY.—No. 5,517. Stereoscopy. Optische Anstalt C.P. Goerz Akt.-Ges.

CINEMATOGRAPHY.—No. 5,422. Outside revolving shutter for cinematograph projection machines. F. Cremer.

CINEMATOGRAPHY.—No. 5,606. Shutters for cinematograph projectors, etc. J. F. H. E. Miller.

CINEMATOGRAPH-PHONOGRAPH.—No. 5,191. Apparatus for synchronising cinematograph films and sound records. F. A. Thomassin.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International

COLOUR CINEMATOGRAPHY.—No. 154,150 (September 3, 1920). The invention consists in a negative cinematograph picture film band taken at the rate of 32 pictures per second, with which the

different colour elements alternate with the elements of an ordinary black and white film, and from which black and white or colour picture positive films can be produced which are susceptible of projection at the ordinary speed employed (16 pictures per second) for exhibition of black and white pictures. Zoechrome, Ltd., and Thomas Percy Middleton, 146, Bishopsgate, London, E.C.2. [Particulars of the process will be found on another page in the "Colour Photography" Supplement.—Eds. "B.J."]

DYE IMPRESSION PRINTS.—No. 158,021 (September 30, 1919). The invention has for object an improved means for obtaining prints direct from photographic negatives by surface contact and independent of the aid of light, thus permitting of utilising a base which is not transparent, for the manufacture of photographic plates and films and of a printing base, which is in no way sensitive to light and may be dried with great rapidity, thus also obviating the expense of glass or celluloid and of sensitised photographic or other specially prepared printing paper for these purposes. It is believed that the only other attempt at this object was carried out under Patent No. 13,874, of 1907 (of F. W. Donisthorpe, "B.J.," January 10, 1908, p. 29), wherein is mentioned the properties of certain chemicals (vanadium chloride in particular) for rendering the silver image of a photographic plate or film impermeable to certain dyes. However, the defect of this invention was that the dye would frequently refuse to penetrate the negative, or would penetrate very unevenly in patches and streaks.

As in Patent No. 13,874, of 1907, the developed photographic plate or film (the negative) is first immersed in a "preparing bath" possessing the above-mentioned properties, and then in a dye bath; the dye absorbed by the negative, being then transferred by contact to a suitable printing medium. The improvement is primarily based upon the discovery that the proportionate penetration of the dye into the negative may be perfectly controlled by the proportion of acid, for example, oxalic acid, in a preparing bath containing, for example, potassium ferri-cyanide or like reducing agent, and a vanadium salt, and upon the discovery that the degree of impermeability to dyes imparted by this preparing bath to the silver image of a negative is far greater than the degree of impermeability produced by the action of light on the bichromated gelatine, used in the Pinatype process. The outcome of such discoveries is that not only can far more rapidly penetrating dyes now be used, but also extremely cheap printing papers, which can be dried with great rapidity by heat.

The process of hardening bichromated gelatine by means of light has not only been employed in the Pinatype process, but also to render an entire coating of gelatine insoluble in hot water for use, for instance, with (other dye) transfer processes, or so hard as to be unaffected even by the higher temperature of a direct flame. It is obvious, however, that a coating of gelatine so hardened cannot be employed on a printing paper for the Pinatype process, since the dyes utilised and known as Pinatype dyes are such as to produce a correct dye image by refusing to penetrate the light-hardened bichromated gelatine of the negative, and therefore refuse to penetrate the surface of a similarly hardened gelatine-coated paper.

The degree of impermeability to dyes obtained in a negative by the aforementioned preparing bath being, as stated above, far greater than that obtainable by light with bichromated gelatine, the slowly penetrating Pinatype dyes may be replaced by dyes, e.g., patent blue, which rapidly penetrate and even possess an affinity not only for soft gelatine, but also for gelatine so hardened as to be insoluble even in hot water at temperatures above 160 deg. F., such dyes refusing, nevertheless, to penetrate the silver image of a prepared negative.

It will now be understood that since the rapid dyes may be utilised under the present invention, the corresponding printing paper may be coated with gelatine hardened by any known process such as the bichromate and exposure to light, or by means of alum, formaline, and the like, the degree of hardening being such that prints obtained on such papers may be dried with great rapidity by heat. The advantage of such rapid drying is not only the increased speed of the process, but also the elimination of all loss of sharpness of the dye image due to the spreading of the dye while the print remains damp.

It will be understood furthermore that since the printing paper utilised under the invention may advantageously possess a surface of hardened gelatine, other more easily obtainable and considerably cheaper papers may also be employed for the purpose; for example, the papers known as baryta-coated papers, art paper, and the like.

If a negative is immersed first in a preparing bath (of the type given in Specification No. 13,874, of 1907) and including a relatively small proportion of acid, such as oxalic acid, and then in a dye bath for the necessary periods, it will be found that the dye will either refuse to penetrate the negative or will penetrate only in patches and streaks. If the proportion of acid is increased, the dye will penetrate more readily and with greater uniformity; moreover, when sufficient acid has been added, the penetration of the dye will be quite uniform and regular, also inversely proportionate to the quantities of silver in the various parts of the negative's surface. If the proportion of acid in the preparing bath be still further increased, the dye will begin to penetrate the silver in the negative until finally the darkest parts are penetrated.

It will now be clearly understood that by means of a preparing bath, the constituents of which have been correctly adjusted in respect to the proportion of acid, the dye can be regulated to penetrate the negative as required, namely, in such a manner that the dye image transferred to the wet printing medium will be the exact inverse of the silver image on the unprepared negative.

The following is the preferred formula for the above-mentioned preparing bath. It should, however, be understood that this formula is only given by way of example, and does not limit the scope of the invention. It is preferred to employ a preparing bath consisting of two stock solutions A and B which are mixed when required for use. Equal parts of A and B solutions are mixed when preparing a negative of average density, the B solution being either diluted alone or the mixture diluted as a whole when preparing a negative having a dense silver deposit.

The preferred formula for the A solution consists of a 10 per cent. solution (by weight) of vanadium oxalate crystals, including a great excess of oxalic acid, and having the following approximate composition:—

Vanadium oxalate	6.5 per cent.
Oxalate acid in excess	73.5 per cent.
Water	20 per cent.

For the B solution a 2.5 per cent. solution by weight of ferricyanide of potassium crystals is usually employed.

The possibility of utilising extremely cheap commercial papers, together with the rapidity with which successive prints may be obtained from the same negative and dried, renders the process extremely advantageous for the purpose of commercial reproduction of photographs, plans, or drawings, when the dimensions of the required prints are relatively great. Many such papers, e.g., the baryta-coated and art papers, do not, however, possess, when dry, surfaces which are transparent, as in the gelatine-coated papers. Such being the case, the efficient use of such commercial papers has only been rendered possible owing to the further discovery that the consequent veiled appearance of a dye image on such papers, most detrimental when depth of colour and half-tones are required, could be obviated by rubbing or coating the surface of the dry print with a clear transparent oil, varnish, or other preparation capable of rendering transparent the surface of the print. Prints when so prepared possess the advantage that they are partially waterproof.—Frank Wordsworth Donisthorpe, 87, Lauderdale Mansions, Maida Vale, W., and Dye Impression Photos Ltd., 24, St. Mary Abbott's Terrace, Kensington, W.14.

The following complete specifications are open to public inspection before acceptance:—

APPARATUS.—No. 158,557. Automatic photographic apparatus. D. Zema.

CINEMATOGRAPH.—No. 158,824. Pocket cinematograph. R. Goldschmied, A. Schey, and L. Zupnik.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

VIDOL.—No. 411,452. Chemicals used for photographic purposes. Johnson & Sons, Manufcaturing Chemists, Ltd., 23, Cross Street, Finsbury, London, E.C.2, manufacturing chemists.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, MARCH 6.

South London Photographic Society. Outing to Merstham.

MONDAY, MARCH 7.

Bradford Phot. Soc. "Amateur Photographer" Prize Slides.
Catford, Forest Hill and Sydenham Phot. Soc. "Fair Lusitania." Rev. H. O. Fenton. Also Print and Lantern Slide Competition.
Cleveland Camera Club. "Use of a Camera."
South London Photographic Society. "Paget Colour Photography." Paget Prize Plate Co.
Willesden Phot. Soc. "Vest-Pocket Camera Work." G. C. Weston.

TUESDAY, MARCH 8.

Royal Photographic Society. Annual General Meeting.
Birmingham Photographic Society. "Some Slides of the Lesser-known North Wales Coast." Bernard Moore.
Bournemouth C.C. Lantern Slide Competition. "Monochrome."
Dennistoun Amateur Photographic Association. Whist Drive.
Doncaster Camera Club. "In a Quiet English Vale." W. Hargreaves Cooper.
Exeter Camera Club. Members' Lantern Slide Evening.
Hackney Photographic Society. "Simple Artificial Light Portraiture." H. W. Fitch.

North Middlesex Photographic Society. "Hints on Camera Making." J. F. Nesbitt.

FRIDAY, MARCH 11.

Bedford Camera Club. "Lenses." P. S. Dudswell.
Birmingham Photographic Art Club. Slide Night.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held March 1, the President, Dr. G. H. Rodman, in the chair.

The President announced with sorrow the death of the hon. treasurer of the Society, Mr. A. H. Lisett.

Mr. Dudley Johnston delivered a lecture, "A Plain Traveller's Tale: Rome and Naples," illustrated by a series of magnificent lantern slides. He dwelt first on the sights of Rome, and particularly on the monuments to the engineering genius of the ancient Romans in the shape of the private palaces of the emperors, brickwork which had withstood the ravages of time and barbarian invaders for 2,000 years. After a glimpse of Tivoli and its famous gardens, he passed to Naples, illustrating his discourse with slides in keeping with the sunshine and hustle of Neapolitan life.

A most hearty vote of thanks was accorded to Mr. Johnston by a large audience.

CROYDON CAMERA CLUB.

Mr. S. H. Wratten, representing himself, bravely demonstrated "Transferotype Paper," representing one of the many products of Messrs. Kodak, and not the least interesting. His courage lay in the fact that, despite long notice, he had, as is usual, postponed acquaintance with this transfer bromide paper until almost the last moment, and then circumstances stepped in which prevented any experimenting. Nevertheless, he said, based on seeing one print developed, and that a dud, he proposed attempting to demonstrate the process before his fellow members, supported by the thought that however things went, "dog never eat dog." If a proper demonstration had been wanted a proper demonstrator would have heen sent.

With disaster apparently unavoidable, a most enjoyable evening seemed assured, and his many friends were obviously bucked in gleeful anticipation. Then came a thoroughly disappointing time, for down on paper, glass, opal, and other materials were the transferotypes squeegeed and stripped without suspicion of a failure. To add to the general sense of injury Mr. Wratten, in haphazard way exposed a piece of the paper hehind a negative to the general illumination of the room and secured a perfect print. It is a pertinent and kindly action to point out to him that the law has ever been careful not to define the word "fraud," which should give rise to reflection, though raising false hopes, may not hring oneself within its scope.

The process being well known need not be discussed, especially as Messrs. Kodak issue a capital booklet covering the ground. It is, however, rather astonishing that it is not more used by amateurs, for unique and very beautiful effects are possible, and the manipulation is simple. Perhaps the pictures transferred to vellum paper were most admired. The lecturer said he had been informed at Harrow that transferotypes made first-class lantern slides. Opinion among the members differed on their use for lantern slides and small transparencies for enlarged negatives, but many thought they seemed admirably adapted for enlarged negatives of the "pictorial" order. This view was supported by some transparencies on glass, which approached carbon in gradation.

In the discussion it was elucidated that for lantern-slides the paper should be fresh, otherwise slight granularity might result. The temperatures given in the instructions should not be exceeded, owing to the Germans not eating so much veal as formerly. Consequently, present-day gelatine falls below pre-war standard, accentuated by the supply being unable to meet the demand. Glass, too, is far below being what it was, and may easily fracture at the focus of a concentrated stare. Mr. Purkis pointed out in reference to sizing, that a half per cent. solution of gelatine remains liquid at ordinary temperatures, and keeps good for a long time with a little thymol added. Mr. Hibbert agreed, one drop of a ten per cent. solution of thymol in alcohol to every ounce preserved excellently (this information is of use for substratums on glass, etc., but the solution is far too weak for sizing most papers used for transferotype supports). Continuing, he said transferotypes are now exclusively used at the Polytechnic as a basis for colouring on ivory. Here, many will think carbon might gracefully be allowed to maintain premier position. Mr. Reynolds inquired whether transfers could be effected on bald heads, an inevitable question with humorists present. He is to be congratulated on getting in first. Among the visitors was Mr. Slater (time and temperature), who confirmed all the demonstrator had said. Mr. Luboshez was expected, but failed to appear. It was conjectured he had been carried on to Brighton lost in thinking out some new variation of dead-front lighting. A most hearty vote of thanks was accorded Mr Wratten for a highly successful evening.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of the dissolution, by mutual consent, of the partnership between Harold Edward Marshall and Cecil Hubert Higson, carrying on business as photographic trade printers, at 251a, Mansfield Road, Nottingham, under the style of Marshall and Company. All debts due to and owing by the late firm will be received and paid by Harold Edward Marshall, who will continue the business.

Notice of intended dividend is given in the case of Daniel Prodger, photographer, Fernbank, Eynsford, Kent, lately residing and carrying on business as C. F. Treble, at 373, Brixton Road, London, S.W. Proofs must be lodged on or before March 12 with J. Osborne Morris, Official Receiver, 280a, High Street, Rochester.

NEW COMPANIES.

L. C. HALL, LTD.—This private company was registered on February 18 with a capital of £1,000 in £1 shares. Objects: To carry on the business of opticians, photographers, manufacturers, importers and exporters of and dealers in photographic materials, etc. The permanent directors are: C. W. W. Hipperson, 103, St. Giles Street, Norwich, chemist and druggist; L. C. Hall, 28, Sandringham Road, Norwich, chemist and druggist. Registered office: 37, Prince of Wales Road, Norwich.

PALATINE ENGRAVING CO., LTD.—This private company was registered on February 23, with a capital of £3,000 in £1 shares. Objects: To carry on the business of process engravers, artists and photographers, printers, stationers, lithographers, etc. The subscribers (each with one share) are: J. Forbes, 88, Adelaide Road, Brockley, S.E., newspaper manager; E. W. Edwards, 120, Brockley Rise, Honor Oak Park, S.E., printers' representative. The first directors are not named. Secretary: G. H. Orford. Registered office: 11, Crosshall Street, Liverpool.

LEES INVENTIONS, LTD.—This private company was registered on February 17 with a capital of £2,000 in £1 shares. Objects: To acquire and turn to account any patents, inventions, devices, novelties, secret or other processes, systems or recipes; to manufacture and deal in iron or other metal, or wood, leather, textile, or other general work, engineers, etc. The subscribers (each with one share) are: A. Bennett, 60, Doughty Street, W.C., photographer; A. E. Walsham, 60, Doughty Street, W.C., photographer. The first directors are: S. Lingwood, F. A. Ellis, A. E. Ellis, S. E. O. Eades, A. E. Walsham, and A. Bennett.

WHETTON, SPARROW & CO., LTD.—This private company was registered on February 23, with a capital of £1,000 in £1 shares. Objects: To take over the business of photographic, scientific and general engineers carried on at Chisold Works, 151, Albion Road, Stoke Newington, as Whetton, Sparrow & Co. The first directors are:—E. P. Whetton (managing director), 67, Albion Road, Stoke Newington, N.; E. Whetton, 151, Albion Road, Stoke Newington, N.; S. C. Whetton, 13, Harcombe Road, Stoke Newington, N.; W. S. Sparrow, 10, Aden Terrace, Stoke Newington, N. Secretary: E. Ashby, 74, Burma Road, N.16.

PRESERVING PICTURESQUE VIEWS.—A correspondent interested in the view-publishing trade states that a movement is afoot to acquire an old and picturesque English village for the purpose of preserving it unchanged throughout the years. It is suggested that some rich landowner should give such a village to the National Trust for Places of Historic Interest or Natural Beauty, which body has promised to keep it in its original condition. The movement has been started because of the many old and picturesque villages which are now being spoiled by ugly modern buildings, and the destruction of ancient houses of real interest. Among the most suitable old and picturesque villages which have been suggested, and which the National Trust has its eyes upon, are Chalford and Painswick in the Cotswolds, Axmouth in Devonshire, Porlock in Somerset, Shere in Surrey, Aldbourne on the Wiltshire Downs, and Chiddingstone in Kent, the latter appearing to be the favourite, though architects appear to have a special liking for one of the stone built villages in the Cotswolds.

News and Notes.

NEOL INDUSTRIAL COLLODIONS, LTD., is the new title of the business formerly known as the New Explosives Co., Ltd., of 62, London Wall, London, E.C.2, concerned in the manufacture of Neoloidine, a British made celloidin, and collodion of various descriptions for photographic purposes.

WISDEN'S CRICKETERS' ALMANAC.—The yellow cover of "Wisden" has been familiar to cricketers for almost as long as that of the "B.J. Almanac" to photographers, for the 1921 issue which Messrs. Wisden kindly send us is the 58th. It runs to 524 pages, and is evidently a most complete record of cricketing events and personalities. Its price is 5s.

THE AERIAL PHOTO CO. has changed its address, which is now 24, Long Causeway, Peterborough. In advising us of this fact, the company sends us its latest price list for postcard printing, together with some examples of its work in black and sepia postcards, both matt and glossy, all of excellent quality. The firm has recently installed one of the latest patterns of Graber printing machine and is able to give prompt delivery of work.

DEATH OF MR. FAYETTE J. CLUTE.—We are sorry to receive the news of the death on January 28 last, at the age of 56, of Mr. Fayette J. Clute, proprietor and editor of our Californian contemporary, "Camera Craft." For many years past Mr. Clute had made his magazine a distinctive photographic organ, appealing to all classes of photographers. It is intimated that "Camera Craft" will be continued unaltered under the proprietorship of Mr. Clute's two sons.

CITY SALE BARGAINS.—The City Sale and Exchange, 90-94, Fleet Street, E.C.4, send us a catalogue of nearly 140 pages listing an immense variety of apparatus both new and second-hand. In the latter class are included roll film, plate, field and studio cameras in a great range of sizes and prices. A special feature is made of apparatus for stereoscopic photography in special reference to the Verascope and Homeos cameras of MM. Richard for which the City Sale are agents in this country. Another French camera which they offer is the Krauss "Tropex" in quarter-plate size, and they also are making a special offer in quarter-plate reflex cameras. The list will be sent free on application.

Correspondence.

** *We do not undertake responsibility for the opinions expressed by our correspondents.*

COLOUR SENSITISING BY MINERAL SALTS

To the Editors.

Gentlemen,—With regard to the extremely interesting papers of Messrs. Capstaff and Bullock and Mr. Renwick, and the letter of the latter, in which he suggests the presence of colloidal silver as the possible cause of the colour-sensitising, or rather the change in size of the particles, it appears to me that a paper by Carey Lea, "Action des rayons lumineux les moins refrangibles sur l'iodure et le bromure d'argent" ("Bull. Soc. Franc. Phot., 1875," XXI., 236), has considerable bearing on the subject, at least in the case of the iodide.

It is quite possible that the above paper appeared in the "B.J." about the above date September, 1875 but I cannot readily refer to the same at the moment of writing. For I gather that he was in the habit of sending original papers to both the "Bulletin" and the "B.J." simultaneously, as the same communications have appeared in both journals as original communications, and both papers were then, as they are now careful to credit contributions culled from other sources.

Lea's paper is somewhat too lengthy to include as a whole, but possibly the following brief abstract may be interesting. He starts

out with the purpose of proving that silver iodide and bromide are sensitive to all spectra rays; that the iodide is more sensitive to the less refrangible rays than the bromide; that E. Becquerel's hypothesis of "rayons excitateurs et continuateurs" is nullified by a careful examination of the phenomena. Lea abandoned the use of the spectroscope and adopted coloured glasses, as being easier to use in practice, and also because one can make quite sure that none but the less refrangible rays are passed by the glasses, and, further, that the glasses could be obtained of any desired dimensions so that simultaneous exposure of the papers to be tested could be made.

Lea floated paper on weak solution of potassium bromide and iodide, in molecular proportions, so that each would consume the same quantity of the silver nitrate bath, which was 30 grains to the ounce; a fresh bath being used each time to avoid contamination of the iodide with the bromide and vice-versa, which might happen, as both silver halides are soluble in silver nitrate. That the alkaline halide used was free from bromides was analytically determined. After salting, the papers were dried between blotting papers, so as to prevent unequal distribution of the salts, as would happen were they hung up to dry. Sensitising was effected by floating on the silver solution followed by washing in running water and drying.

Commercial red glass was used, and in order to set some criterion of exposure a negative was placed in contact with the papers. Two kinds of red glass were used, a dark and a medium, and the limit of absorption of these combined was wave length 594. When two dark glasses were used the limit was 600; with three dark ones the limit was 605, and the maximum of transmission was beyond this. With two glasses, limit 594, an intense direct image was obtained on the iodised paper in five minutes. On the bromide paper, exposed simultaneously, nothing was obtained, and long development gave but a feeble trace of an image. Under the two glasses with limit 600, it was impossible to obtain an image by development on the bromide paper, even with 1½ hours' exposure to sunlight at midday in January. On the other hand, the iodised paper gave in twenty minutes a trace of a feeble direct image, that is one visible without development. Under three glasses, limit 605, the iodised paper gave in thirty minutes, sunlight exposure, a feeble image, but with four hours a vigorous one, both these tests were developed. Bromide paper exposed side by side with the above gave nothing, and with four hours' exposure and development prolonged for some hours, only the faintest trace of an image was discernible.

Lea repeated these experiments under yellow glass, that is under a brown and a green, the limits of absorption of which were 638 and 527, and with a maximum of transmission at 570, and came to the conclusion that both the bromide and iodide of silver were sensitive to these rays, but the latter more so than the former. Using green glasses with an effective region of 517 to 569, the iodised paper gave more vigorous images in five minutes than the bromide in 3½ hours. Further experiments were carried out with admixture of the two halides, but it is unnecessary to enter more fully into Lea's conclusions, as access to the original papers is obtainable in the libraries of the R.P.S. and the Patent Office The developer used was the well-known physical one of gallic acid, silver nitrate, and acetic acid.

It would seem reasonable to suppose that if the above results are sound, the increased red-sensitiveness of the iodide-treated emulsion is easily explicable on the assumption of a mere external skin of AgI, and there is no necessity to assume the existence of colloidal silver, because Carey Lea's sensitive salts were not ripened, at any rate, in the present-day acceptation of the word, and were formed without a vehicle like gelatine. But this would not explain the action of the sulphurous acid or potassium cyanide. Mr. Renwick, in his letter ("B.J.," 1920, p. 743), states that iodide, cyanide and sulphite of silver are not known to exist having a strong absorption in the yellow, orange and red of the spectrum. But have the two latter salts ever been prepared in the form of an emulsion and spectroscopically examined? Both are sensitive to light, and it should not be a very difficult matter to prepare emulsions of the same, considering their comparative insolubility in water, and thus test them out either in the spectrograph, or, following the above method, under coloured filters; the latter method being preferable from a time-saving point of view. And if a neutral wedge was also used some comparative idea of the relative sensitiveness could be obtained.

Both the silver halides are soluble in sulphites and cyanides, so that one is tempted to ask whether one might not have partial solution with the formation of a double salt, which might be sufficient explanation of the conferred red-sensitiveness without the hypothesis of the formation of colloidal silver, presuming that these two salts were found to be colour sensitive.—Yours truly,

E. J. WALL.

Cambridge, Mass., U.S

FIRING FLASH POWDER.

To the Editors.

Gentlemen,—Referring to your report in to-day's issue of Mr. D. Charles' paper on "Improvements in Flashlight" at the Royal Photographic Society, your reporter is not quite correct in the remarks attributed to me. I mentioned that the only "absolutely certain" method of firing flash powder, as far as my experience was concerned, was a braided cigar light held in a small spiral at the end of a copper wire, and pushed into the powder, and that a ceric iron igniter, provided the disc was kept clean, was almost equally satisfactory.

Perhaps you will kindly insert this correction and oblige.—Yours faithfully,

ARTHUR G. BANFIELD.

49, Old Bond Street, W.1.
February 25.

THE PROFESSIONAL'S DEVELOPER: CONCENTRATED M.Q.

To the Editors.

Gentlemen,—In my article on the above subject, in your issue for February 25, there is an unfortunate mistake. This is probably an error of my own in correcting the proofs, and I can only plead in extenuation that I was in bed with influenza at the time. As stated under the heading, "The Amount of Sulphite," the latter should be about six times the reducing agent, and the formula needs revision accordingly. It should read :—

Metol	¼ lb.
Hydroquinone	½ lb.
Soda sulphite	4 lbs.
Caustic soda	1 lb.
Water to	2 gallons.

Dilute one part with 10 to 15 water.

In the article the sulphite was given as 2 lbs.—Yours faithfully,

P. M. JONES.

Brockham Green, Surrey,
March 1

To the Editors.

Gentlemen,—May I be allowed to offer a criticism on the composition of the developer advocated by Mr. P. M. Jones in your latest issue? The formula that he advises contains :—

Metol	4 ozs.
Quinol	8 ozs.
Sol. sulphite	32 ozs.
Canstic soda	16 ozs.
Water to	320 ozs.

The chemical formula for metol is $C_6H_4NHCH_3$, OH, $\frac{1}{2}H_2SO_4$, which gives a molecular weight of 172. In order to form the free base this weight requires 40 of caustic soda; to form the sodium salt, C_6H_4, $NHCH_3$, ONa requires 80 parts of caustic, so that 4 ozs. of metol require 1.86 of caustic. Hydroquinone, $C_6H_4(OH)_2$, molecular weight 110, also reacts with two molecules, or 80 parts of caustic soda, to form the phenolate $C_6H_4(ONa)_2$, so that 8 ozs. of hydroquinone will combine with 5.8 of caustic soda. From my work on "rodinals" I have found that the least excess of caustic over the quantities indicated above lends to rapid deterioration of the developing strength. But Mr. Jones advises 16 ozs. of caustic, where the maximum admissible is 1.86 + 5.8 or 7.66 ozs.;

and in my experience, a somewhat smaller proportion, say 7 ozs. to 7½ ozs., would be ample. The proportion of sulphite recommended by your contributor is 32 ozs. in 320 ozs. of water. If this is anhydrous, it is as much as will dissolve; but if the crystalline sulphite, 64 ozs. should be used to get the maximum stabilising effect.—Yours faithfully,

W. F. A. ERMEN.

Alderley Edge,
February 28.

To the Editors.

Gentlemen,—*Re* article "The Professional's Developer," I beg to point out that there is an inconsistency between Mr. Jones's article and his formula. He states that the sulphite should be six times the amount of the reducing agent. As the reducing agents are ½ lb., then the sulphite should amount to 4½ lbs. instead of 2 lbs. as in the formula. Mr. Watkins gives the proportion of soda carbonate as 2½ to 2 of sulphite, and if as Mr. Jones states 1-12 of the weight of caustic soda be as effective as the carbonate, then the amount of caustic should be 3¾ ozs. instead of 1 lb., or if 4½ lbs. sulphite is right then 6 ozs. caustic.

The idea of a concentrated developer is a good one, and I was feeling inclined to mix according to formula, but cannot help thinking that there is a mistake in it. Perhaps Mr. Jones would be good enough to go into the matter.—Yours faithfully,

K. A. NORTON.

Whitchurch Road,
Cardiff.

KEY INDUSTRIES AND THE P.P.A.

To the Editors.

Gentlemen,—At the last Council meeting of the P.P.A. the secretary is reported to have called attention to the "interesting correspondence" in the "B.J." on key industries, and it is stated that it was agreed to postpone discussing the subject. One would imagine that the importance to photographers of being able to obtain a full supply of the raw material of their industry at reasonable prices would be so self-evident that the Council of the organisation that professes to exist for the purpose of protecting their interests would have had the matter constantly before them, and, instead of treating it as something to be talked about at some future occasion, would have already taken whatever steps are possible to deal with the circumstances we have to face.

Combinations among manufacturers are always heralded with the proposition that by large-scale production production is made cheaper. So it may be, but experience shows that the benefits thereof rarely reach the consumer. Take soap or sewing cotton or tobacco for instance, each an industry that has now reached, under combination, the position of almost entirely eliminating competition, with the result that we are paying for our everyday requirements a price that is quite unjustifiable by the cost of material, labour and organisation.

In our own circle we have "the unanimity," as some one has called it, which has been organised for the sole purpose of stifling that healthy competition that makes for economy and efficiency in production. Under the circumstances of war, that prices of both raw and manufactured material should become advanced, even inflated, was inevitable; but we ought to be returning by now to more healthy conditions. Since the last advance in the price of plates, glass has fallen very considerably, silver is less than half the price, all the chemicals are greatly reduced, but we are getting no reduction. The prices of plates are now higher than the highest charged in 1850, when the conditions of manufacture were primitive compared with those existing at present.

Under the captivating cry of protection for British industries strong effort is being made to promote legislation to exclude foreign material from our markets. If it should succeed there will be an immediate rise in prices of that home produced. A certain British-made developer was quoted 80s. a pound some little time ago, when it was thought that, under a certain Order in Council, the German product was unimportable. Then came a rumour that this was not so. The price dropped to 60s. The rumour became a certainty, and there was a further big drop. This illustrates the effects of protection. Photographers are not less patriotic than any other class of the community, and as sincere in their desires to protect the industries of their country; but they are quite clever enough to realise that protection of one class at the expense of another is not a beneficial kind of protection. Unfortunately, we are not an influential class, and have little power to make known our opinions or to protect ourselves against imposition. It is the more disappointing, therefore, to find that the P.P.A., which we should be able to look to to safeguard our rights, takes so languid an interest in this matter, which affects us much more materially than those the Council appear to be so engrossed in. The annual picnic is very well in its way. It is a pleasant outing for those who can attend it, and it is not without its uses. Perhaps the "Circular" also may have its uses, notwithstanding it is, probably, the most feeble and the most costly attempt at journalism that is published in this country. The 8d. or so per number which it appears to cost might surely be applied to better purpose, but I suppose we ought not to complain, as we get it for about its true value.—Yours truly,

M. P. P. A.

PANCHROMATIC PLATES.

To the Editors.

Gentlemen,—I have read the most interesting article on panchromatic plates, and think that possibly short notes on the results of an amateur, who has used them since their introduction, may be useful. About May of last year I started to take up photography after a lapse due to the war, and have exposed a goodly number of plates, mostly on subjects which are intended to be pictorial. Roughly—I have no records—I should say that my percentage of plates and films would be films 30 per cent., ortho. plates, including the screened variety, 35 per cent., panchromatics 35 per cent., non-corrected nil. A short time ago I was preparing a set of my best prints, say three dozen. When I had done these I found that well over 60 per cent. were on panchromatic plates, nearly all being taken with a screen increasing the exposure three to four times, one or two being with a deeper screen to give full correction.

There are two disadvantages with these plates:—

(1) An under-exposed negative on a panchromatic plate is more hopeless than on any other—the shadows frequently being clear glass.

(2) Owing to the difficulties in manufacture, or probably inspection, small blemishes in the plates are more common than with other types, and this necessitates careful spotting if the negatives are small ones which require enlarging.

I prefer Ilford formula pyro-soda for developing, and this will normally give the kind of negative I want in 5 minutes at 60 deg. Fah., when diluted with 25 per cent. water.

Using a Radiolite watch, as suggested, it is preferable to alter the dilution to suit the temperature, and keep to a standard development time of 5 minutes, which can easily be read on the watch. Smaller intervals being difficult to gauge, as the luminous markings are not usually made to minutes.—Yours faithfully,

S. H. HALL.

Elliot Vale, Blackheath, S.E.3.

FACTORIAL DEVELOPMENT.

To the Editors.

Gentlemen,—Like another of your correspondents I have often wondered why the factorial system is not more popular than it is to-day. Your correspondence pages, however, have opened my eyes, and I think I can now understand why so many decline to use the system. In short, the personal factor appears to enter too largely into the working of it, different results being obtained by different workers, even though they use the very same make of plates and developers.

The factor numbers are the trouble. The makers of such numbers are too dogmatic and precise. Had the plan of saying, "Factor

from — to — " been adopted (*vide* Mr. Jones's instructions given on page 108, " Watkin's factor, 12 to 15 "), instead of that of giving a definite number, the system would have been more useful.

All reference books, for instance, give Azol as 30, as also do the makers, though for many years I have advocated and used a factor of 35. And now Mr. Willis comes along and says (page 119) Azol 25! The lowest I have ever heard of for Azol. We thus get three different numbers for " normal development " with Azol, and may, of course, have many more, according to our ideas of normal density. Some may argue that the possibility of using different factors and getting any kind of negative desired by using the factorial system, is a strong point in its favour. This, indeed, may be so, but it is not the point of my argument.

Had I known nothing of the system and taken Azol as having a factor of 25, as given by your correspondent—who, it is clear, is a good practical worker—the result obtained would not have been to my liking (I prefer 35), and rather than be bothered I might have turned down the system as being unsuitable, and for ever afterwards used either dish or tank. And Mr. Willis might have done the same had he taken at the start my factor of 35. He and I, however, happen to be of an experimental turn of mind, and we found our own factors. But all workers will not make such experiments, hence some dissatisfaction at times with the set factorial numbers, or the system as a whole.

A present-day objection—and a growing one—to the factorial system, is the necessity of having to expose a rapid film to a red light in order to ascertain the correct " time of appearance." This has to be done at a time when the film should really be carefully shielded from the light. In the case of ordinary plates this exposure to a red light may do no harm, but with the ultra-rapid plates we have to-day the " time of appearance " period is more likely to be looked upon as being the " time of fogging."—Yours faithfully,

H. GREEN.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's " Journal " must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. B.—The firm which produces the Mackenzie Wishart goods is Mackenzie and Co., 212, Old Dumbarton Road, Glasgow.

J. E.—Both Messrs. Houghtons and Messrs. Kodak supply materials for a system of card indexing dealing with the recording and execution of orders in a studio establishment.

H. C.—8s. 6d. is a reasonable enough price for the post-cards, but we must say we are not surprised that your customer should be dissatisfied with the out-of-focus effect. We agree with him; the difference in definition between the two eyes is a marked defect.

S. D.—As regards patents, if you know the name of the patentee, it is a fairly rapid business to find a patent in the annual indexes of the Patent Office Library; but, of course, the Patent Office does not attempt to connect the trade names under which goods are sold with the names of the patentee. That would be an enormous job.

B. J.—A copper dish lasts fairly well for use with a developer which does not contain ammonia in any form, but not as well as a steel dish, nor, of course, as one of enamelled metal or " granitine." But if the dish is thoroughly rinsed after use, and not left with alkaline developer adhering to it, it will last for a very long time.

S. S.—The collected researches of Hurter and Driffield are published here by the Royal Photographic Society, 35, Russell Square, London, W.C.1. Messrs. Tennant and Ward, 103, Park Avenue, New York, are the sole selling agents in the United States. Any application from the United States to the Royal Photographic Society would be referred to Messrs. Tennant.

A. P.—We should doubt, from what you tell us, if there is likely to be any great advantage in fitting up a gas installation as supplementary to daylight. But, at any rate, the choice among studio gas lamps is very small. There is a lamp supplied by the Kodak Company as the " Powerful," and Messrs. Griffins still supply very excellent inverted burners (Howellite) specially for making up into studio installations, but they do not supply the latter complete.

P. J.—You are correct in assuming that the main effect of " rust " on a lens is to slow it. In a bad case, with ordinary plates, this might be to the extent of 50 per cent. The only precaution necessary in buying such lenses is to reject any which are perceptibly yellow when looked through; the surface iridescence is of little note. The tin boxes referred to have been offered at many furniture and ironmongers' shops in London, *e.g.*, Black and Co., 50-51, High Holborn.

E. M.—We expect your customer wants the enlargements framed in the passe-partout style, but with celluloid instead of glass. There is no special firm doing this kind of work; any of the trade enlargers could do it. Or your assistants could easily make up the enlargements in this form, using celluloid sheets, such as are obtainable from Greenhill and Sons, 8, Water Lane, Butcher's and other people supply the necessary binding strips and ring hangers for the passe-partouts.

J. S.—Your Meyer lens is of 3¼-inch focal length, and the pre-war price was £2 5s. It is a good average wide-angle lens. (2) " Instruction in Photography," by Abney, is out of print, but you are pretty certain of being able to get a copy from Messrs. Sotheran and Co., 140, Strand, London, W.C.2. (3) About the best book on lenses is " Photographic Lenses," published by Messrs. R. and J. Beck, 68, Cornhill, London, E.C.3. We think it is still obtainable from them. If not, apply to Messrs. Sotheran. (4) As regards your other queries, we find it rather difficult to know exactly what you want. For quarter-plate we think a useful focal length for long-focus work is 12 inches; 18 inches to 24 inches for half-plate size. No useful purpose in having these lenses of greater maximum aperture than *f*/8 or even *f*/11. (5) For a good all-round anastigmat for quarter-plate and half-plate respectively we should suggest a lens such as an *f*/6.8 anastigmat of 5½ and 8 inches respectively.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3175. Vol. LXVIII. FRIDAY, MARCH 11, 1921. Price Fourpence.

Contents.

SUMMARY.

A new regular feature of the "British Journal" appears this week in the shape of "Paris Notes," contributed by M. L. P. Clerc. It is intended that an article of this kind by M. Clerc should appear each month, and should give an account of photographic events in France. (P. 134.)

In his first article M. Clerc describes the great increase in its activities which the French Photographic Society has witnessed since the Armistice, and which has its evidence in the holding of eleven meetings monthly. He also refers to a new non-halation plate, and to a lens of *f*/1.5 aperture. (P. 135.)

A dull annual general meeting of the Royal Photographic Society livened up at the end when the views of the dark-room group, presented under the personal direction of Mr. C. P. Crowther, were heard. (P. 143.)

For "soul" in a photograph, use chiffon—is a maxim solemnly reported from a meeting of the R.P.S. Pictorial Group. (P. 144.)

The inventor of an automatic machine for while-you-wait photography has hit upon a happy device for ensuring the expeditious service of an anticipated stream of customers. (P. 134.)

In a leading article we lay emphasis on the practical information for the use of the persulphate reducer contained in the paper by MM. Lumière and Seyewetz, which we published a week ago. It may be said that a satisfactory explanation of the characteristic action of persulphate has yet to be found. (P. 134.)

In a contributed article, Mr. Arthur G. Willis lays stress on the business merits of the carbon, platinotype, and silver print-out processes, and urges the special claims of these media in the making of portraits of distinction. (P. 136.)

A provisional programme of the forthcoming Congress of the Professional Photographers' Association will be found on page 141. The Congress on Thursday, April 21, is to visit the Harrow works of Messrs. Kodak, Ltd. (P. 141.)

Both non-members and members of the P.P.A. are free to send in their work to the forthcoming exhibition of professional photography, which, this year, will have a technical section. (P. 133.)

Mr. C. Goodwin Norton, familiar to many lanternists of the past generation, sends us some practical notes on the doctoring of parts of camera woodwork which stick. (P. 146.)

A scientific paper issued by the U.S. Bureau of Standards describes the theory and practice of using a photographic method for the detection of changes in groups of objects, e.g., in the disclosure of military camouflage. (P. 138.)

Constructional details of an enlarging, printing, and copying camera, and of a telephoto lens, are contained in two recent patent specifications. (P. 142.)

EX CATHEDRA.

The P.P.A. Exhibition.

The prospectus of the exhibition of professional photography to be held by the Professional Photographers' Association in conjunction with the forthcoming Congress has now been issued and is obtainable from Mr. Marcus Adams, 43, Dover Street, Piccadilly, London, W.1. As was the case last year the exhibition is open to any professional photographer, whether a member of the P.P.A. or not. An entrance fee of 5s. is charged, which covers any number of exhibits and includes the cost of packing and postage for their return. Exhibits must not be either framed or glazed, but simply mounted on thin white or light-toned mounts of outside dimensions either 16 x 12 inches or 20 x 16 inches. This year, in response to a feeling which was expressed twelve months ago, a section of the exhibition will be set apart for technical, as distinguished from portrait, professional photography. For the purposes of the exhibition "technical photography" has been defined as covering every branch of photography other than portraiture. It is to be hoped that those both within and outside the Professional Photographers' Association will provide the selecting committee with an entry which will make it possible to bring together a thoroughly good and representative collection of professional photographic work. The last day for the receipt of exhibits and entry form is Thursday, April 7. Both are to be sent, not to Mr. Adams, but to Mr. R. N. Speaight, 157, New Bond Street, London, W.1.

* * *

Desensitisers in Bromide Printing.

The treatment of exposed bromide paper with an aqueous solution of amidol (1:2,000) in order to allow of the development being conducted in a bright yellow light, is an obvious variation of one of the experiments which led Luppo Cramer to the so-called Phenosafranine process. It is a debateable point, however, whether the slight gain in comfort in the dark room resulting from desensitisation with amidol solution is worth the risk, and until further information is available regarding the influence of such treatment on the rate of development, etc., we would caution any of our readers against submitting large prints to this operation. We hope to publish some further notes by Mr. Crowther on such points in the near future, but we can say at once that, provided development after desensitisation be continued to the same factor as would ordinarily have been given, the apparent speed of the bromide emulsion is unaltered. If, on the other hand, a simple time method of development is employed, the results after desensitisation are liable, as a correspondent has indicated, to lead to the assumption that the amidol solution has partially destroyed the latent image. Staining of the paper by aqueous solutions of developing substances is also a factor which needs careful consideration, and the well-known resistance of such stain to washing

out with water, even after an acid fixing bath has been used, are further deterrents to experimentation with large or valuable prints.

* * *

Paris Notes. We have a good deal of pleasure in making the announcement that a further regular feature of the "British Journal" will be a series of notes dealing with photographic matters in France, contributed by M. L. P. Clerc. A leading member of the French Photographic Society, M. Clerc is widely known, not in France only, but in other countries, by his writings on photography and particularly by two very excellent text-books dealing with branches of photo-mechanical work. After a strenuous career during the war, when he rendered valuable service in the technical branch of the Photographic Section of the Aviation Service, M. Clerc has associated himself with several of the leading French photographic journals, and is thus closely in touch with photographic developments in his country. The first instalment of his notes, which will be found on another page of this issue, fairly represents in its range of topics the comprehensive scope which his articles will aim to exhibit. Subject to the necessity of finding space for matter calling for immediate publication, we hope to include these "Paris Notes" in the second issue of the "British Journal" of each month.

* * *

Appropriate Framing. Now that larger sizes than the cabinet are becoming the usual thing in high-class studios it is essential that the portraitist, who wishes his work to be displayed to the best advantage, should endeavour to secure orders for any frames which may be needed. He can thus avoid the perpetration of such outrages as framing a red carbon in a crimson plush or other unsuitable setting. There is now a tendency to sombreness in photography, but it need not be intensified by the unvarying use of black or dark brown woodwork, suitable as these may be in most cases. Light sketchy work will appear to advantage in oxidised silver, with perhaps a silvery grey veneer mount. Coloured work is nearly always safe in a narrow gold moulding with or without "Louis" embellishments. A few sample frames should be kept ready for insertion of the stock sizes of mount, as few customers are competent to judge the effect of a frame from samples of moulding. The prices charged for frames should not greatly exceed those charged by local frame makers, and we recommend that the photographer should arrange with one of these to make those of his frames which are not purchasable ready made. Home framemaking is not profitable on a small scale.

* * *

Next, Please. Every portrait photographer has good reason to regard the prosperity of his business as threatened by a new invention which we see described in a Continental journal. It is an automatic machine of somewhat elaborate construction. You take up a position in front of it for delivery of your portrait in a few seconds. If you want a full length, you set a certain lever; if a head and shoulders, another lever; and if you desire the print to be seented, you make still a third adjustment. Then when you are ready for the exposure to be made, and press a button for that purpose, gramophones within the interior of the machine discourse to you and tell you when the exposure has finished. But a further feature of this invention is one which extorts our respect for the thorough-going genius of its designer. If you do not move quickly away, after having received the portrait through the delivery-slot of the apparatus, hydraulic mechanism comes into operation and squirts a jet of water over you. We are unable to gather whether notice of this stage of the process is communicated to the customer. Possibly it is, by the performing gramophones. At any rate it suggests the healthy optimism of the inventor, who clearly has in his mind's eye a queue of customers. It might be supposed from the effective method chosen for persuading each to make way for the next that the machine owes its existence to some aimable Prussian. Strangely enough it appears to have been inspired under the soft skies of Italy.

THE PERSULPHATE REDUCER.

To the average photographer it may appear somewhat surprising that so much attention has been paid by scientific investigators to the reducing action of solutions of persulphates, for the aforesaid average photographer has learned, frequently by costly personal experience, that this reducer is a most fickle servant only suitable for use by experts. In the hands of those who have obtained control of this reagent, however, it constitutes one of the most valuable chemicals in one's equipment. It is undoubtedly unique in its reducing action when correctly applied, and is capable of converting hopeless results of the "soot and whitewash" variety into negatives eminently suitable for use, even in the enlarging lantern. Hitherto, perhaps, this reducer has appealed more particularly to the amateur photographer, but with the present-day tendency of the professional to devote an increasing proportion of his time to subjects other than portraiture, it will not be inappropriate to offer a few comments on the very interesting communication by MM. Lumière and Seyewetz which appeared in our last issue.

In the first place it is evident that the scientific investigators of our profession are alive to the importance of such a reducing agent as persulphate, and also to the fact that failure to get it to exert its characteristic "depth" reduction is all too prevalent. An investigation into the cause of such failure and the evolution of a safe formula which will be reliable in all districts, with all types of tap water, therefore merit commendation. We certainly thought when we read the communication from the Eastman Research Laboratory on the influence of traces of iron salts that we were arriving at a clearer understanding of the tantalising variations so often met with when using persulphates, but now it appears that the presence of iron salts, *per se*, is not necessarily the cause of these variations. Even the chemically pure persulphate will play tricks on us if the conditions under which we use it are not carefully controlled. For example, the worker in Glasgow or Manchester may get it to work perfectly immediately after dissolving it in tap water, whilst the worker in London may have to wait days after making up the solution before it becomes active enough to cause any reduction. Exactly why this is so can be readily understood from MM. Lumière and Seyewetz's work. They have shown that the reducing action is only exhibited by acid solutions, and that the pure neutral salt when dissolved in distilled water rapidly becomes acid, its activity being correspondingly enhanced. All hard, alkaline waters, therefore, affect the reducing action of persulphate, the action only manifesting itself when the acid developed on storage has overcome the natural alkalinity of the water. Further, it is to be noted that the characteristic depth reduction propensities of persulphate solutions are vitally affected by the concentration of acid present, and also by the presence or absence of certain salts which are, in varying amounts, to be found

in most samples of tap water. It appears, therefore, as though we are only assured of success with this reducer if its solution is made up with distilled or very pure and soft tap water. If we wish to make certain of similarity of action at all times it is advisable to compound the solution (6 grains ammonium persulphate to each ounce of water is, in our experience, quite strong enough for all ordinary purposes) as required, and to add *one drop* of concentrated sulphuric acid to each ounce of solution. We can confidently recommend a solution compounded in this way; used freshly prepared on well-wetted negatives we cannot recall a single failure in our personal practice for several years.

When we come to consider the theory of the process we are not so fortunately situated, and we have little hesitation in saying that a satisfactory explanation of the peculiar action of persulphates as reducers has not yet been published. It is somewhat significant that the characteristic depth action of this reducer is most apparent on silver images embedded in gelatine. We have not had an opportunity of investigating the matter strictly quantitatively, but comparative experiments with negatives in collodion against those in gelatine, leave little doubt that in the case of the former there is practically no evidence of depth reduction. It is clear, therefore, that the old idea that metallic silver catalyses the reducing action, speeding it up in proportion to the amount of silver present, will have to be abandoned. Perhaps, by combining the recent observations of Lüppo-Cramer on the depth development properties of amidol solutions with those of MM. Lumière and Seyewetz on the influence of free acid in the persulphate solution, a satisfactory explanation of depth action may be forthcoming. The latter experimenters suggest that at the surface of the negative, where the shadow images preponderate, the silver-ammonium sulphate first formed acts, under correct conditions of acidity and persulphate concentration, as a physical intensifier. As the reducing solution penetrates the gelatine, not only is the concentration of the persulphate lowered by virtue of the oxidation of the gelatine, but also as Lüppo-Cramer has shown, the concentration of acid is reduced; reduced in all probability to a point below that at which it will cause the excess persulphate to react on the silver-ammonium salt. Physical intensification will therefore not occur in the depth of the image. Such an explanation is, of course, put forward tentatively, but in view of the difference in the action of persulphate solutions on images in collodion and gelatine, the point is worth further investigation. We therefore commend the matter to the attention of those of our readers who are interested in photographic technics

PARIS NOTES.

In undertaking, on the kind invitation of the Editor of the "British Journal," to contribute every few weeks notes on photographic doings in France, it seems advisable in this first communication to say a few words on the place which is occupied in French photographic affairs by the Société Française de Photographie, which is the equivalent in France of the Royal Photographic Society. The French Photographic Society was established in 1854, and began the publication of its "Bulletin" in the following year. Since 1905 it has occupied its present house at 51, Rue de Clichy, Paris, a building which is owned by a small company composed of some of its members. On the ground floor is a lecture hall seating 250; the four upper floors include offices, library, club rooms, a testing laboratory for the examination of lenses, shutters, etc., two studios and numerous dark-rooms. Unfortunately, there is no accommodation for the permanent exhibition of the valuable collections of specimens and apparatus relating to the old processes of photography and of the various applications of photography which the Society possesses. The taking of larger premises came up for discussion some years ago, but the plans were interrupted by the war. Up to the year 1910 the proceedings of the Society were limited to two monthly meetings, one of which consisted of a lantern exhibition of members' work and the other a series of monthly instruction evenings. In 1910 several technical sections were successively formed. During the war the active life of the Society was very greatly restricted; on the outbreak of hostilities its premises were taken into use as stores and work rooms for the Aviation Service, the staff of which at the outset was largely recruited from its most active members. But since 1919 the Society has entered upon a period of remarkable activity, shown by its large increase of membership and by the holding of eleven meetings per month. The general monthly meeting is devoted to the presentation of original works by the authors, of minor items of practice, and to the exhibition and description of new apparatus, materials, etc. At the sectional meetings scientific photography, cinematography, process work, colour photography and studio portraiture are particularly dealt with; and there is a course of weekly lessons for beginners in addition to meetings for students, for the trial of new processes and a monthly lantern evening which is frequently accompanied by a practical discussion on some special application of photography, and is almost always lightened by musical selections. English photographers who may be passing through Paris are cordially invited to visit the Society's headquarters, where they may obtain an invitation to attend any of these monthly meetings.

Relief on the Screen!

A good deal of publicity has been given in the cinematograph journals, and even in some of the scientific periodicals, of an alleged great invention of a Dr. J. L. Pech, of Montpellier, who, by using a concave projection screen, claims to produce the effect of relief in the projected cinematograph pictures. The somewhat involved theory of the inventor unfortunately received a severe blow on a public demonstration given in Paris, at which none of the spectators, however much they tried and wherever they placed themselves in the hall, were able to perceive any relief effect. It can only be assumed that the projection lens possessed a somewhat curved field, giving a lack of definition at the margins when a flat screen was used, and that the concave screen almost corrected this defect.

A New Non-Halation Plate.

The black backing used on the glass side of English plates as a preventive of halation has never been very popular in France, where, except for panchromatic plates, a coloured film between the glass and the emulsion is preferred. A new anti-halation plate of this kind has been put upon the market by MM. Guilleminot. The film underlying the emulsion is formed of manganese peroxide suspended in gelatine. The brown colour of this coating disappears in an acid fixing bath. Similar means have been previously employed, notably in the Lumière "Simplex" plate, but the special feature of the new plate is the very slight opacity of the yellowish-brown film, so that the latter presents no obstacle to the control of development by examination of the plate by transmitted light in the ordinary way. I may mention also that MM. Grioshaber

have recommenced the manufacture, discontinued some years ago, of a sensitive salted paper, which gives very fine matt prints.

An f 1 5 Lens.

A new optical firm, the Société Optis, has entered on the manufacture of cinematograph lenses. Their "Galear" of *f*/3.5 aperture and of five glasses covers sharply a field of more than 45 deg., and their "Aetar" of *f*/2.5, and of six glasses, one of more than 40 deg. The firm announces that the series will be extended for photographic work, and that they have in course of construction, to be placed on the market shortly, a lens of *f*/1.5 aperture.

New Projection Lamps.

Makers of the ordinary optical lanterns and of cinematograph projectors are striving to secure the highest efficiency from incandescent electric lamps of the clustered or focus type working at from 12 to 20 volts. Several large cinema theatres have already adopted a "Radius" projector fitted with a lamp of 1,200 c.p. consuming only 500 watts, whilst smaller optical lanterns for amateur use have shown their ability to give satisfactory projections of Autochrome on a 5-ft. screen with a consumption of 100 watts.

A further interesting new introduction in cinematograph projection is the "Garbarini" arc lamp, which has only one carbon. The other electrode consists of a hollow tungsten ring, which is placed concentrically with the carbon and is kept cool by a current of water. Suitable coils give a rapid rotation of the arc, which thus traverses a circle of about ¼-in. in diameter, producing an intense light which does not suffer any masking. Feed of the carbon is controlled by an electric motor through a bi-metallic plate which normally is kept curved by the radiation of heat from the arc, but which straightens itself and cuts off the current when the arc tends to enter the interior of the annular electrode.

X-Rays and Paintings.

Reviving a method suggested in 1914 by Faber (a German), Dr. A. Chéron has obtained some interesting results in the use of X-rays for the examination of paintings. Whilst the old painters used almost exclusively mineral colours opaque to X-rays on wood panels or canvases treated with carbonate of lime transparent to these rays, modern painters make chief use of lake colours transparent to X-rays on canvases treated with white lead opaque to these rays. Thus, fraud in the renovation or alteration of an original painting of ancient date is readily detected. Unfortunately, it will be very easy for forgers of old paintings to adjust their practice to this modern method of detection.

Pictorial Photography.

One of the promoters of pictorial photography in France has just died in the person of M. Maurice Bucquet. As founder and president of the Photo-Club de Paris, he did a very great deal towards inspiring and encouraging this group of amateur workers. The annual exhibitions of the Photo-Club and the handsome "Bulletin" which the Club issued were a revelation to the French public of numerous artists in France and abroad. It is to be hoped that the loyal co-workers of M. Bucquet will be able to revivify the Paris Photo-Club, all signs of life of which had ceased before the war. The only exhibition of pictorial photography which exists in France at the present time is that which is organised by the firm of MM. Poulenc in their premises, where are also periodically given some very interesting lantern exhibitions.

Travel and the Film.

Several concerns engaged in the transport business are now using the cinematograph as part of their advertising campaign. Some time ago the Compagnie Générale Transatlantique, the most important of the French shipping companies, produced a very interesting film having as its subject the route traversed by their road motor services in regular operation in Tunis, Algeria and Morocco. This film is shewn, with others, illustrating travels in Cote d'Azur, Corsica, the Alps and the Pyrenees, in the offices of the Compagnie Française du Tourisme, established with Government assistance and with that of the leading touring associations, for furthering travel in France.

The French Physical Society will hold on March 31 and April 1 this year its annual exhibition of new discoveries in pure and applied physics, together with newly introduced scientific and industrial appliances. In these exhibitions, the sequence of which has been interrupted by the war, there have been almost invariably new introductions connected with photography in one way or another.

Personal.

I close this first series of notes by announcing that at its meeting of February 25 last the French Photographic Society had the honour of admitting as life members Sir William J. Pope and Mr. F. F. Renwick, the researches of both of whom on scientific methods relating to photography have attracted much notice in France. It is to be hoped that close relations between associations pursuing the same ends on each side of the Channel will be formed, and, if I may speak for myself, it will be a very great pleasure to contribute to that end.

L. P. Clerc.

DISTINCTION—AND THE PRINTING PROCESS.

The standing of a studio in the estimation of the public is determined by the prints it sends out. This is an obvious fact, but one apparently often overlooked; for how else can one account for the fact that when a new business is started, or an established one taken over, much time and thought goes to the selection of the various apparatus and to the choice of plates and mounts? But the printing process usually "decides itself," if we may use the expression, as if bromide were the only practicable process. That there are others it is the aim of this article to point out, but before going on to review them a few words may be necessary on the desirability of leaving bromides on one side if really distinctive work is to be turned out and good prices are to be obtained. It will be as well to state here that if quantity rather than quality is your aim these notes will be of little interest to you.

"Something different" is the aim of every progressive studio, because it is recognised as the one certain way of obtaining business. Even a cut-price line often fails to attract clients, but the draw of prints that are "different" never fails, the public is always on the look out for the man who turns out work out of the ordinary rut, and the farther you get out of that rut the better for your business.

Frequent attempts are made to get this distinction into results by unusual lighting or posing; these methods are useful in some special cases, but for routine work they carry their own certain destruction, insomuch as they can never be successfully applied to all types of sitter. To score a hit with a line-lighted profile of a lady with well-formed chin and neck is frequently the prelude to a request to repeat the performance on a lady with a larger share of chins than of artistic taste. For special subjects, of course, one must go outside the standards of lighting and pose, but to make a standard line of such a production is to court disaster.

But a printing process does not suffer from any such limita-

tions. A sepia carbon of a many-chinned matron will have the same distinctive qualities as one of a more swan-like damsel. The quality has not to be striven for, it comes automatically as the result of using the particular process. You are therefore free to concentrate on obtaining the best possible presentment of your sitter without the need of striking originality in every negative. This difference in methods of obtaining distinctive prints is one very apt to be overlooked, but it is one of the greatest practical importance.

Probably the reason most likely to persuade the good class worker to go off the beaten track in printing is the very fact that the new process taken up will be actually different from bromide. It at once provides an answer to that question, so difficult to dispose of sometimes. "Why is it that I can get postcards at Mr. Blank's for 5s. a dozen, and you charge me two guineas for prints very little larger?" A different process, different in essentials as well as in details of surface and manipulation, is a thing your clients will appreciate and pay for. The cheap-jack may be able to follow you in lighting and posing, but he cannot successfully imitate your results if you forsake bromide as your printing medium.

This need not mean resource to daylight as the printing light; carbon and platinotype may be printed perfectly well with an artificial light installation, and P.O.P. may be used in the same way. But even if daylight is used the troubles supposed to be inseparable from it are by no means insurmountable. The speed of bromide printing can, of course, never be equalled, but speed is not everything. Clients really do not mind waiting a fortnight instead of a week, providing they can see the advantage of so doing; in fact, the refusal to be hurried is a mark of many high class studios, who find it a paying stand to take up.

Providing negatives are kept reasonably thin and quite free from fog no trouble need be anticipated in the holding up of orders in the printing room. There is one point which will need careful watching when changing over to a daylight printing process: the quality of the negatives must be first class. Bromide papers will give a passable result from most negatives, but carbon, platinotype and P.O.P. demand really good negatives. This is not altogether a disadvantage, as it ensures that any falling off in negative quality will be noticed. The exclusive use of bromide papers frequently leads to a great deterioration in negatives, and this means more work for the retoucher and printer and a subtle, but none the less real, deterioration in the prints. With a daylight process this falling off is so obvious that it may be instantly recognised.

If daylight has the disadvantage of being variable, and sometimes least in evidence when most needed, it has also advantages, as its suitability for vignetting or for shading parts of a print; and there is no light so "easy" on retouching or knife work on the negative. Direct sunlight is ideal for the production of soft prints from hard negatives, while by printing through green glass vigorous prints may be obtained from soft negatives.

Figures, even rough ones, are frequently of very great help to a man without practical experience who wishes to decide on a process. Therefore, as a *very* rough estimate one may say that an "average" studio negative should yield at least three prints per day, even on a dull winter day, when P.O.P. is used, both carbon and platinotype are rather faster, and might give four prints instead of three.

Having cleared the ground to a certain extent we may now pass on to consider the three chief processes, carbon, platinotype, and P.O.P. silver paper.

It has been said that a greater variety of effects are obtainable by the carbon process than by the use of all other printing materials combined. This is by no means an over-statement, the range of effects is absolutely unlimited, yet each effect can be repeated whenever required; this is a point the advantage of which cannot be over-estimated. With a development process, or, still more, when a print is toned, the colour will vary with each batch of paper and with every sample of chemical employed; with carbon the colour is definite—it is the colour of the pigment, and does not alter with different treatment or with the depth of print; double tones are impossible, and stains of any sort can only be caused through gross carelessness. The variety of effects on carbon may be gauged by a few facts. There are over 30 distinct colours of tissue on the market. Each of these may be placed on *any* paper base,; there are over a dozen different bases sold especially for the purpose. In addition to this any print may be given a matt, semi-matt, platino-matt or even a glossy surface. There is something wrong with a picture that cannot be suited with such a range as this.

If portrait films are used there is no need to go beyond single transfer printing; double transfer has the name of being a troublesome process, although personally I have never found it too lengthy; the one extra operation seems well worth while when the advantages of a non-reversed print from the film side of a negative are taken into consideration. Considerable control may be exercised over the contrast of carbon prints by variations in the sensitising bath, which is one reason why it is best to do your own sensitising.

The quality of a carbon print is the very finest possible; to many workers it would be a revelation to see a carbon alongside a bromide from the same negative. Carbon surface, carbon effect, and other such claims for bromide papers are stretched too far, because the carbon effect is inherent to the process, and cannot be obtained in any other way. As remarked above, good negatives are essential, and there is one other point which should be noted. When a print has been made on carbon tissues the negative should be carefully wiped over before it is printed by any other process; this is necessary, because traces of bichromate will cling to a negative, and when transferred to bromide paper will cause insensitive spots.

Carbon enlargements used at one time to be made by the use of enlarged negatives, but most of this work is now done by using a bromide enlargement as the starting point; this enables high-class work to be turned out at reasonable prices. There seems every reason to expect that the same process will be used for contact prints when "Carbro" becomes better known, but of this I cannot speak, as I have had no opportunity of testing the latest developments in this direction under practical work-room conditions.

Platinotype paper is gradually coming down in price, but it seems unlikely to be within the reach of any but really high class businesses for some years yet. It is an extremely fine paper: without having anything like the same range of effects as carbon, it has sufficient variety to make its exclusive use possible without monotony. The quality is quite as fine as carbon, but of course of a different type. One does see poor prints on platinotype, but they are almost always the product of stale paper. As the two "class" processes, it is usual to compare platinotype and carbon. Such comparisons are not of great value, but they do indicate roughly what are the most notable points in a paper. We may say that while the quality of either is irreproachable carbon has the greater variety, and platinum is the more easy to work, and lends itself better to the quick production of prints.

As there is no "film," in the ordinary sense of the word, on a platinotype paper, it presents an ideal surface for working on; for this reason, if for no other, it is the finest of all materials for high-class sketch work. The normal grey black image is a very good colour for this type of print, while the sepias obtainable are also of an excellent quality.

Satista, the platinum-silver paper, is a very satisfactory medium between platinum and bromide; it partakes more of the quality of the former than of the latter. It will attract many who are looking for a high quality material without being prepared to go so far as genuine platinotype. The sepia grade in this is also an excellent paper. In the important factor of permanence, Satista stands above bromide, which is to say that it more than fulfils any conditions imposed on it by the average user, without quite reaching the "ever-lasting" permanence of carbon and platinum. But one may say in passing, that any paper sold commercially in these days will give prints good for fifty years under ordinary conditions. The permanence

of a print depends not so much on the nature of the paper as on the proper manipulation of it.

To write on P.O.P. to professionals is a somewhat dangerous task. The fixed idea about P.O.P. seems to be that it has a glossy surface and gives purple-brown prints. This may be an over-statement, but certainly there are very few users who make the most of this paper. There are, of course, two distinct types, one with a gelatine emulsion and the other with a collodion one. The results on either are very fine if proper methods are used. In fact, a print on a matt surface collodion paper toned with gold and platinum is of as high a quality as can be desired; this type of paper is usually of a most attractive surface, whatever finish is given to it. Matt, semi-matt or glossy, the paper has a "finish" comparable to that of carbon, though not mistakable for it. The range of tones is very wide, from red chalk to black brown; they are easy to control, but it is not always easy to exactly match a print made months before.

Collodion papers are rather more delicate to handle than are gelatine ones, but they have a decided advantage in being less affected by heat; so much so, indeed, that they may be washed in warm water and dried over a fire. The greatest cleanliness is essential in dealing with any print-out-papers. They are, of course, the ideal material for use when much dodging has to be done during printing.

Having briefly reviewed the possibilities of the most important non-bromide papers there remain a few remarks still to make. I have several times mentioned the "quality" of prints. This is a most elusive factor, but a very important one. It is frequently claimed on behalf of bromide papers that they are indistinguishable from carbon or platinum; this is claiming too much, because, although their range of contrast and gradation may be identical, their physical construction, the silver being embedded and sunk in gelatine, makes just that difference in quality in the print which makes your customer content to pay a higher price for your work if it is done on a non-emulsion paper.

There is one problem which the head of any large studio will find a very difficult one to solve if a non-bromide printing process is taken up. It is the problem of the printer. Even before the war good carbon and platinotype printers were difficult to find, and now they seem to be quite unobtainable. The only way, one would say, is to train your own. This is a big undertaking, but one that will pay in the long run. An intelligent man may become an efficient bromide or platinum printer within a month of taking up the process, but it would take a good six months to train a man to proficiency in all the ins and outs of carbon or P.O.P. work. Training, or rather lack of it, is responsible for the general decline in the standard of photographic work, and it is up to us to put our house in order in this matter.

Cost of production is an important point. Under this head one may suggest that bromide is by far the cheapest process, because it absorbs less labour than any other. The actual materials for either carbon or P.O.P. cost no more, but the extra time spent on them must be charged on the cost of the print. Next comes Satista, and then platinotype at the head of the list, but these last two are becoming cheaper, and certainly are economic both in labour and in waste materials.

In conclusion, any high quality printing process may cost you more, but it enables you to obtain a big increase in price for your results, and leads to the ambition of all good workers —more work and better quality.

ARTHUR G. WILLIS

A PHOTOGRAPHIC METHOD OF DETECTING CHANGES IN A COMPLICATED GROUP OF OBJECTS

THE method to be described has been used for some time in certain branches of physics[1] and astronomy[2]. It was recently independently devised by the writer and developed in co-operation with Dr. H. E. Ives, recently of the United States Air Service, for use in military operations. The method is, however, applicable to a so much wider range of uses than the fields in which it has yet been employed that it seems desirable to describe the method and a few of its possible applications.

Fig. 1.—First photograph. This illustrates the initial appearance of the pile of rocks.

The method may be described as follows: A negative is made of the group of objects in which a change is expected. After the change is supposed to have occurred, a second negative is made with the same camera (or one of the same kind) on a plate of the same kind and from as nearly as possible the same position as used in making the first negative. A positive is printed from one of the negatives, is superposed upon the other negative so as to bring them into register, and the combination is viewed against a source of light. When the photographs are properly made, those parts of the combination which correspond to the unchanged portion of the group of objects will appear as a field of practically uniform

Fig. 2.—Second photograph, illustrating the appearance of the pile of rocks after a few changes in it have been made.

[2] Harvard College Observatory Circular No. 79, p. 1.

especially the astigmatical aberrations as same has hitherto in general not been obtained with telephoto objectives. The objectives according to the invention mentioned differ from the above example of Patent Specification No. 3,096 of 1914 by the collective cemented surface and according to the invention, with a view to obtain a sufficiently large collective effect, the difference between the two refractive indices of the glasses on the cemented surface must be at least 0.02 for the D line of the spectrum: besides the absolute value of the radius of the cemented surface should not exceed the value of the focal length of the telephoto objective.

The drawing shows an example of the objective.

In the following table are enumerated the dimensions with respect to the constructional example as represented in the drawing which apply to the focal length 100, and the numerical values of the different kinds of glass.

$r_1 = +18.091$		$d_1 = 3.329$	
$r_2 = -38.834$		$b_2 = 0.130$	
$r_3 = -36.679$		$d_{II} = 0.83$	
$r_4 = +38.740$		$b_1 = 5.66$	
$r_5 = -10.393$		$b_2 = 18.25$	
$r_6 = -9.426$		$d_{III} = 1.89$	
$r_7 = -17.130$		$d_{IV} = 0.75$	
	I	II	III	IV
$n_D =$	1.59234	1.59704	1.62410	1.49300
$n_C' =$	1.60464	1.61718	1.64732	1.50840

A telephoto objective corresponding to the example given may suitably be employed up to an aperture ratio of 1 : 6.3, which is comparatively large for a telephoto objective.—Carl Zeiss, Jena.

The following complete specifications are open to public inspection before acceptance:—

LENSES.—No. 158,902. Photographic lenses. Optische Anstalt C.P. Goerz Akt.-Ges.

New Books.

CASH FROM YOUR CAMERA.—A little book with this title reaches our table from the American Photographic Publishing Co., Boston, Mass., by whom it is published, price $1. Its text deals with the somewhat old theme of selling reproduction rights in photographs here and there to magazines, or for issue in postcard, advertisement and other forms, but it gives a good deal of useful advice to the amateur commercialist seeking recompense in these directions. Its most valuable part, however, and also the largest, is the directory of such buyers of rights in the United States. These are chiefly magazines, from each of which the author of the book has obtained brief information of the kind of photograph, both as regards subject and printing process, which is acceptable. The list includes also firms buying photographs for the illustration of their products, and there is a separate list of magazines and various undertakings who did not reply to the letter of inquiry.

TELEPHOTOGRAPHY.—A second edition of the very useful practical manual, "Telephotography," by the late Cyril Lan-Davis, has been issued by Messrs. George Routledge, with revisions by Mr. L. B. Booth, scientific optician for Messrs. J. H. Dallmeyer. It contains a brief biographical notice of Mr. Lan-Davis, who disappeared whilst on service with the Royal Naval Air Service in Gallipoli, and is supposed to have perished at sea on a journey from Gallipoli to Malta in a small boat. Mr. Booth has made comparatively little alteration in the work, his revisions and additions relating chiefly to commercial types of telephoto lens which have latterly been introduced, notably by himself. The manual remains an excellent guide to the optics (in simple form) of the telephoto lens and to the practical use and usefulness of these objectives. There is not a point of any importance to the practical telephoto worker which is not treated in it. The price is 3s. 6d. net, bound in stiff boards, or 4s. 6d. bound in cloth.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MARCH 14.

Bowes Park and Dist. Phot. Soc. "Toning" (Hypo-Alum). F. C. Hornsey. "Toning" (Sulphide). A. H. C. Roberts.
Bradford Photographic Society. Members' Print Night.
Cleveland Camera Club. R.P.S. Portfolio. Fred Judge.
Cripplegate Photographic Society. "Transferrotype." J. Brown.
Dewsbury Phot. Soc. Y.P.U. Members' Lantern Slides.
South London Phot. Soc. "British Landscape Portfolio."
Willesden Phot. Soc. "Truth in and about Photography." T. H. B. Scott.

TUESDAY, MARCH 15.

Royal Photographic Society. (1) "The Design and Construction of the Reflex Camera." A. S. Newman. (2) "The Use of the Reflex Camera." Adolphe Abraham, O.B.E., M.A., M.D., B.Sc.
Birmingham Phot. Soc. "Stories of Dartmoor." F. W. Pilditch.
Bournemouth C.C. "X Ray Photography." A. Thomas.
Exeter Camera Club. "Carbro Printing." Fred Walker.
Hackney Phot. Soc. "The Possibilities of a Small Camera." E. Human.
Leeds Photographic Society. Members' Lantern Evening.
Portsmouth C.C. "With Allenby through Palestine." W. Butcher and Sons.
Rotherham Photographic Society. "The Gum-Bichromate Process." J. M. Fitzclarke.
Sheffield Photographic Society. "Portraiture." T. Lee Syms.
Stalybridge Phot. Soc. "Mounting Photographic Prints." W. Harwood.
Walthamstow and Dist. Phot. Soc. Affiliation Print Portfolio (1919).

WEDNESDAY, MARCH 16.

Accrington Camera Club. Whist Drive.
Borough Polytechnic Phot. Soc. Lantern Slide Competition.
Croydon Camera Club. "Truth in and about Photography." T. H. B. Scott, F.R.P.S.
Dennistoun Amateur Photographic Association. "Autochrome Slides." W. Partridge.
Edinburgh Phot. Soc. "Enlarging and Toning." G. Ritchie.
Halifax Scientific Society. Rambles with "Nature, the Old Nurse." H. Waterworth.
Ilford Photographic Society. Visit to South Essex Camera Club.
Partick Camera Club. Lantern Slide Competition.
Woodford Phot. Soc. "Amiens Cathedral." E. W. Harvey Piper.

THURSDAY, MARCH 17.

Birmingham Phot. Soc. "Lantern Slide Making." R. Hancock.
Brighouse Photographic Society. Members' Prints and Slides.
Camera Club, The. "An Excursion Down the Rhone from Lyons to Marseilles." C. E. Keyser.
Everton and District Phot. Soc. Members' Print Night.
Gateshead and District Camera Club. "Bromoil." G. Tennant.
Hammersmith (Hampshire House) Photographic Society. "A Ramble in the English Lake District." A. J. Linford.
Hull Photographic Society. Members' Slides.
Kryn and Lahy (Letchworth) Phot. etc., Soc. "A Dive into Belgium."
North Middlesex Phot. Soc. "How we saw Lugano." Messrs. Fincham and Ridge.

FRIDAY, MARCH 18.

R.P.S. Pictorial Group. "Pattern in Pictures." T. H. B. Scott.
Bedford C.C. A.P. and P. Slides, with Criticisms. (Ladies' Night.)
Birmingham Photographic Art Club. Annual Exhibition.

SATURDAY, MARCH 19.

Walthamstow and Dist. Phot. Soc. Visit to Wallace Collection.

ROYAL PHOTOGRAPHIC SOCIETY.

There was an undertone of unrest in the gathering of members at the annual general meeting, held on Tuesday evening last, the president, Dr. Rodman, in the chair. The signs of it were not evident on the surface, but had come before every member in the shape of the names on the ballot paper for election of council of those forming a "dark-room group," and banded together for the purpose of providing greater facilities for practical work in the Society's house. A number of junior members occupying back rows of seats were pointed out as this dark-room group of reformers. But nothing was heard from them during the formal proceedings. It was the tamest of annual meetings. The president suggested that the report of the council should be taken as read, and discussed paragraph by paragraph. Then he read almost every line of it, but without a word of comment being forthcoming. A

wearisome quarter of an hour followed, during which Mr. C. H. Oakden recited the income and expenditure account and the balance-sheet item by item. A single objection by Mr. Gear to a description of one item provoked a short discussion, which ended in the motion that a line of type should be placed one-eighth of an inch lower down; and that was all

Mr. J. B. Portway then read the report of the scrutineers of the ballot for the election of members, which had resulted as follows:—President, Dr. G. H. Rodman; vice-presidents, Sir W. J. Pope, F.R.S., and Mr. W. L. F. Wastell. Ordinary members of council, Messrs. A. J. Bull, D. Cameron-Swan, G. Bellamy Clifton, C. P. Crowther, G. I. Higson, J. Dudley Johnston, Ernest Marriage, F. Martin-Duncan, E. W. Mellor, C. H. Oakden, F. F. Renwick, T. H. B. Scott, E. Sanger-Shepherd, W. F. Slater, J. C. Warburg, S. H. Wratten, and Major F. C. V. Laws.

Owing to the death of the treasurer, Mr. A. H. Lisett, having taken place after the ballot paper had been issued, in which he was the only nominee for the treasurership, the council, on the advice of its solicitor, had decided to elect a treasurer at its first meeting. A motion that it should do this was proposed, seconded and carried.

The most interesting part of the proceedings was the presentation to Mr. F. F. Renwick of the Progress Medal of the Society, which had been awarded to him. The president referred to previous distinguished recipients of this honour, such as Abney, Hurter and Driffield, and MM. Lumière. Mr. Renwick, who was present to receive the medal, was greeted with loud applause.

Votes of thanks to the officers and staff followed, and also the motion that the auditors, Messrs. Calder Marshall and Ibotson, should be re-appointed and receive an honorarium of 5 guineas; and with this business concluded, the president declared the meeting closed.

Were the proposals of the dark-room reformers, defeated at the ballot, to go unspoken? No, up sprang Mr. C. P. Crowther, all persuasive smiles, and from the front bench appealed to the president, that the views of his "constituents," as he called them, in the back rows should be heard. "Quite irregular," said Dr. Rodman, "but let us hear them." Then one after another made known an awful state of things. A lack of heating in the dark-rooms and studio, a dilapidated condition of these premises, the absence of adequate equipment, and a state of unfitness which one speaker instanced by pointing out that the Society's print-trimming desk was used for crushing chemicals. Another speaker urged that the facilities should be such as would enable the junior members to produce works worthy of the Society's exhibition. He appeared to think that this object would be secured by the provision of a dry-mounting press. The "Royal" title of the Society was given much emphasis in these appeals. It seemed to be the view of the speakers that a Royal society is one having everything on a lavish scale. It was pointed out by several members that those able to use the Society's dark-rooms formed a very small proportion of the membership and that the funds of the Society required to be expended in the interests of members as a whole. The president also made it known to the "reformers" that certain of the things which they had asked for in a memorandum to the council had actually been ordered before the memorandum was received, but it appeared to be the settled view of the dark-room group, and one from which they derived much satisfaction, that the things they wanted had not been taken in hand until, as one speaker amiably put it, "a shindy had been kicked up." However, the president having declared that the equipment of the work-rooms should have the attention of the council, Mr. Crowther performed soothing gestures in the direction of his protegés, and the informal proceedings were at an end.

ROYAL PHOTOGRAPHIC SOCIETY—PICTORIAL GROUP.

Mr. J. J. Butler presided at a meeting of the above group, when Mr. R. H. Lawton opened a discussion on "Chiffon: Its Use and Abuse." Mr. Lawton made a humorous reference to the wide application of the title of the subject, and presumed he was expected to speak on its application to enlarging. He thought chiffon was one of the greatest friends of the photographer, but that it was fatal to the true rendering of light, especially when its effect was exaggerated. True halation, as distinct from the effect of reflection from the back of a plate, was a natural phenomenon often desirable in pictorial work, and was an encroaching of the lights upon the darks. The tendency of chiffon was to spread the darks over the lights and to produce a general fog; hence it seemed that the use of such a diffuser was more desirable in the making of the negative than in the making of the positive.

Mr. Lawton thought that chiffon was extremely useful in portraiture, as it tended to reduce contrast and gave a softening of contours, while retouching marks were almost entirely eliminated. Soul could be imparted to a picture by its use with discrimination, and Mr. Lawton showed several comparative prints in support of his contentions.

Mr. Weston exhibited a test negative of an ingenious character especially made for the purpose of ascertaining the effects produced by a number of diffusing screens. These were generally of a regular mesh and varied in pattern and mesh. A copper gauze gave a different effect when blacked, and a perforated zinc screen increased contrast, while a screen of chiffon with an open centre produced marginal diffusion only. Mr. Weston did not approve altogether of some of Mr. Lawton's conclusions, and contended that chiffon properly used gave breadth, roundness of edge and retained the vibrating edge which was so essential to sunlight effect. He thought that diffusion in itself was not a merit, and certainly should not be adopted in the representation of a busy scene.

Mr. Dell caused a slight flutter by declaring that chiffon was used by some workers to camouflage an untrue rendering of tones, which it did by causing a general fog. This statement, however, did not meet with general approval. An interesting suggestion was made by Miss Venables, who uses chiffon in the diaphragm slot. This, she claims, gives the best results, with none of the objectionable features obtained by using it in front of the lens. Mr. Banfield showed a 1/16-in. brass gauze which he places in the diaphragm slot when making the negative. This arrangement can only be carried out when using a rectilinear lens, owing to lack of room in an anastigmat.

Several members spoke on the relative merits of differently-coloured diffusing media, but there seemed no concensus of opinion in favour of any particular colour, except to denounce the use of white material.

Miss Warburg showed up the usefulness of portfolio criticisms by saying that when one used a single thickness of chiffon the critic said, "Use chiffon," but when a double thickness was used the critic asked, "Why use chiffon?"

Mr. Wormald had experimented with chiffon behind the lens in making the negative, and found that, with a white bust as a subject, a white line was formed round the contour.

The discussion proved entertaining and most instructive, and also indicated a field for experiment by pictorial workers who aimed at definite results.

CROYDON CAMERA CLUB.

It has been told, on the usual undoubted authority, that a genial investigator, with no leaning to prohibition, on returning home late one night distinctly saw a procession of blue peacocks, all playing trombones. Mr. F. R. D. Onslow in his lecture last week on "Sea birds" had nothing approaching this phenomenon to record. Nevertheless, with the happiest colloquial style, fund of humour and set of slides, both instructive and technically excellent, he kept a large audience interested and amused for nearly two hours.

The Scilly Isles, Devon and Cornwall, Lundy Island, and the Bass Rock furnished his main hunting grounds for splendid sport involving no slaying. Many slides depicting the same characters were neatly woven into "tabloid" romances of the O. Henry order. One out of many is selected as conveying a moral. It dealt with the love affairs of two seagulls, finally merging into the fatal trio. All went smoothly at the start, the hen evidently being favourably impressed by the attentions of her wooer. This, in turn, favourably impressed the cock bird with a sense of his own worth, and confident of a conquest made he flew to an adjacent rock and complacently preened his feathers, omitting to keep an eye on his fiancée. But there was an observant rascal round the corner who seized the opportunity so successfully that the old love was speedily forsaken for the new. The last sad scene depicted the abandoned male (as Grundy has observed, "never an attractive spectacle") furious but impotent, being heartily laughed at by his pals.

The lecture attracted two bird specialists from afar, and in the discussion Mr. C. B. James, who once travelled 300 miles to examine a gullery and yet appears perfectly sane, narrated some experiences. Mr. E. G. Gilbert-Cooper gently chided Mr. James for stealing eggs, and said that the intensely interesting lecture they had heard represented patience amounting to genius. Mr. Onslow, in reply to a hearty vote of thanks, modestly remarked that patience did not enter into a pursuit when one was absorbed in it. He had heartily enjoyed himself all the time.

News and Notes.

HOUGHTON'S PROFESSIONAL BULLETIN, in its current issue, illustrates a selection of the new styles in mounts, to which Messrs Houghtons, Ltd., are just now giving prominence by offering to send a set of specimens for half-a-crown.

THE GLASGOW HERALD is now publishing, in its issue of Wednesday in each week, a column of notes on "The Art of the Camera," and is fortunate in having as its contributor Capt. Owen Wheeler, since there are few who, like him, unite an experience of nearly half a century in all branches of photography with the gift of writing "readably" even on matters of a technical kind. In the first instalment of these notes, published on March 2 last, Capt Wheeler has some good advice to give on buying large-aperture lenses, and promises us something fresh on the eternal question of depth of focus.

CAMERA CRAFT.—A pamphlet from the office of "Camera Craft" informs us that Mr. Fayette J. Clute, whose death we announced last week, will be succeeded in the editorship by Dr. D'Arcy Power, who for many years has been associated with Mr. Clute as a regular contributor to the magazine, and, as readers of our pages know, is the author of many original contributions to photographic practice. A notable one of these is the vertical enlarger, of which Dr. Power, if not the inventor, is the modern reviver who has given this apparatus a practical form corresponding with present-day requirements. We wish Dr. Power well in his new office, which we are sure will be excellently discharged, for he is one of the best writers connected with photographic journalism in the United States, and, moreover, one who is a first-rate practical man and fully informed in photographic processes. With Dr. Power will be Mr. Edgar Felloes as associate editor.

TRADE WORK FOR COMMERCIAL PHOTOGRAPHERS.—Messrs. Lilywhite, Ltd., West End, Halifax, send us some specimens of their commercial photography in the shape of some altogether excellent photographs of machines, motor vehicles, mechanical fitments, and other manufactures. In every instance the technical quality into which blocking-out, working up, etc., largely enters, is of the highest class. Messrs. Lilywhite point out that they specially lay themselves out to do the printing from photographers' "commercial" negatives, undertaking the necessary preparation of these for prints of the effective kind which they themselves supply. This is a special branch of trade work for which undoubtedly there is a considerable demand. Many portrait photographers who undertake commercial commissions find the chief obstacle in the necessity of retouching methods to which their staff are unaccustomed. If they could get it done and prints made as well as Messrs. Lilywhite evidently can do these things, many of them, we are sure, would be able to make commercial work a larger part of their businesses.

JAPANESE LANTERN SLIDES.—Mr. J. F. Mitchell Roberts, who has returned to London after a five years' residence in Korea and Japan, showed at last week's meeting of the South Suburban Photographic Society a series of 200 of his photographic lantern slides coloured by Japanese artists. Many of the slides were coloured in Prussian blue, but the colouring was so artistically and lightly distributed as not to be monotonous or really noticeable. Slides of this colour throughout—seascapes, etc., by "moonlight"—gained the loudest applause from a meeting to which non-photographers were invited. Comment was made upon the few colours used and the sparseness of the same, indeed some of the slides were so lightly tinted—though most effectively so—as to appear almost devoid of colour until contrasted with black and white slides, the Japanese apparently getting the most artistic effects by using as little colour (aniline dyes, it is supposed) as possible, and putting that little in exactly the right place. It was pointed out by some artists and students of colour present that in many instances the placing of the chief colour or colours could be more clearly seen when the picture on the screen was looked at with but one eye, and that partly closed; in one noteworthy example, a forest scene, examined in the manner described, it was seen that the actual dye work consisted of but five fairly well-defined patches of brown dabbed on the foliage, the dabs being so artistically and scientifically placed and balanced that the whole of the foliage appeared to represent autumnal tints. The Japanese are past-masters in the art of slide colouring, and the many amateur colourists who were at the lecture no doubt learned many useful lessons, thanks largely to the ease with which the screen could be approached and the 6 ft. pictures examined. Mr. Roberts has an extremely valuable collection, and one that should be seen at the Royal Photographic Society, and probably would be, were not Mr. Roberts such a busy man in the engineering and mining world.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of the dissolution, by mutual consent, of the partnership between Benjamin Foulkes Winks and Herbert Irving Bell, carrying on business as camera manufacturers at 662b, Seven Sisters Road, N., under the style of Adams Manufacturing Company. All debts due to and owing by the late firm will be received and paid by Benjamin Foulkes Winks, who will continue the business.

Notice is given, pursuant to Section 242 (5) of the Companies (Consolidation) Act, 1908, that the names of the undermentioned companies have been struck off the Register of Joint Stock Companies, and the companies have been dissolved:—Colourgraphs, Ltd.; Progressive Pictures, Ltd.; Trade Photographers, Ltd.; Victor Photographics, Ltd.

NEW COMPANIES.

H. SLADE (AGENCIES), LTD.—This private company was registered on March 1 with a capital of £2,000 in £1 shares. Objects: To carry on the business of lithographers, photographic printers, etc. The subscribers (each with one share) are: H. Slade, 14, Paternoster Square, E.C.4, manufacturers' agent, and Mrs. M. A. Slade, 161, Brockley Rise, S.E.23. H. Slade is the first director.

MARGARET EDGAR STUDIOS AND PHOTOGRAPHIC SUPPLY CO., LTD.—This private company was registered on March 3, with a capital of £3,000 in 10s. shares. Objects: To carry on the business of artists, photographers, printers, art publishers, artists' colourmen, artists' supplies stores, etc. The permanent directors are H. Mansell, Lightcliffe Bank, Alcombe, Minehead; Margaret E. Mansell, Lightcliffe Bank, Alcombe, Minehead. Secretary, H. Mansell. Registered office: Friday Street, Minehead.

UNDERWOOD AND BARKER, LTD.—This private company was registered on February 25 with a capital of £1,000 in £1 shares. Objects: To adopt an agreement with Leon C. Underwood for the sale to the company of certain chemical formulæ, and to carry on the business of manufacturers of and dealers in chemical, optical, photographic materials, etc. The first directors are: L. C. Underwood, 10, Little St. Andrew Street, W.C.1; F. G. Barker, 14, Parklands, Surbiton Hill. Registered office: 10, Little St. Andrew Street, St. Martin's Lane, W.C.

AUTOMATIC ADVERTISING CO., LTD.—This private company was registered on March 1 with a capital of £50,000 in £1 shares. Objects: To carry on the business of automatic advertising contractors, advertising agents, photographers, publishers, printers, etc. The first directors are: A. Mitchell, 51, Elsham Road, Kensington, W.14 (director, Mitchell's Pictures, Ltd.), and E. T. Simpson, 52, Belsize Park Gardens, N.W.3. Qualification, £2,000. Remuneration, £200 each per annum. Secretary, R. J. Muxworthy. Registered office: 66, Shaftesbury Avenue, W.

PLATE PRICES AND ORDERS.

To the Editors.

Gentlemen,—I think most of your readers will agree that, considering the falling price of silver and glass, it is more than time that plates followed suit. I suggest to my fellow professionals that they adopt a ca' canny policy, and in place of ordering plates in bulk for future requirements order frequent parcels in minimum carriage-paid lots. This will entail more trouble, but will have the advantage that when the drop does come they will not have large stocks at the present excessive prices, and it should persuade the "unanimity" that it will be better business to present their customers with a reduction rather than pay the money to the railway companies.—Yours faithfully,

W. Foster Brigham, F.R.P.S.

15, The Promenade, Bridlington.
March 7.

FACTORIAL DEVELOPMENT.

To the Editors.

Gentlemen,—The correspondence on this subject is both interesting and useful, and I should like to "butt in" with my small experience and raise a question which perhaps some of your more experienced readers can answer.

What is the permissible percentage of error in both factorial and time and temperature development not perceptible in the result?

That excellent book, the Watkins Manual (5th edn.), makes two statements which hardly seem to agree. One is that two developers—the same, but one with bromide and one without—at the same temperature will give the same steepness of gradation in the same time. The other is that the temperature coefficient of a developer is much higher with bromide than without. Pyro is given at 1.9 with bromide and 1.5 without.

I made one or two small experiments to find which of these statements is correct, but got no definite result, and as the variation in time of development was about 10 per cent., I came to the conclusion that an error of 10 per cent. is immaterial.

My usual developer is a one-grain pyro, without bromide, used with a factor varying with the subject of 9 to 12 for direct printing and 6 to 9 for enlarging. The suggested Watkins factor is 18.

In spite of Mr. Watkins' good advice not to fall between two stools, I frequently use the time and temperature method for developing six to a dozen plates in a dish, and from an experimental record I find that of eight similar outdoor subjects developed for six minutes, three were of 30 seconds appearance, three were 40 seconds, and two 45 seconds. The results were good, though one or two were too harsh for enlarging, but developed factorially there would have been a variation in development time of 12 to 50 per cent.—Yours faithfully,

A. E. Avent.

Hartland Road, Kilburn, N.W.6.
March 5.

To the Editors.

Gentlemen,—The discussion certainly clears the air and has served a good purpose.

If I had to give a working definition of a "Watkins' Factor" it would be "The total time of development which gives the contrast in the negative considered right by the photographer, divided by the time of appearance of the high light."

But it is obvious that anyone (like myself) publishing factors cannot tell what type of printing process, subject, and therefore negative, the man who reads his information requires. In giving factors, therefore, an instruction book or leaflet can only give them for a definite degree of contrast, and in my trials of years ago that contrast was a steepness of .9 on the H. & D. system.

Here is the warning on the point which I have issued with factors in every one of the nine editions of my "Watkins' Manual" printed in the last 19 years: "It must be clearly understood that although I give definite figures for different developers, they are a guide for the first trial only, and may require modification to suit other photographers' fancy as regards contrast. The best amount of contrast (a steepness of gradation) for one printing process is probably not the best for another, and here, again, the experience of the old photographer may lead him to modify the factor."

What Mr. Green considers to be a difficulty and objection peculiar to factorial development is really an equal difficulty and objection to any other possible way of giving information on development.

I, for one, am very grateful to Mr. A. G. Willis for stating exactly how he modifies a factor for different types of studio lighting and printing processes.—Yours truly,

Hereford. March 6. Alfred Watkins.

DOCTORING APPARATUS THAT STICKS.

To the Editors.

Gentlemen,—Most photographers at some time or other have trouble with those parts of their apparatus which slide together. The remedies for sticking and jamming are various—black-lead, glycerine, grease, glass-paper, etc. However well-seasoned wood may be, it is liable to swell and shrink if exposed to damp or heat. Take one example first. The slide of the studio back begins to be troublesome. Often the first thing done is to take it right out and sand-paper the part that enters, and also the part that is entered first. This makes matters worse. The slide should be perfectly parallel, and the part into which it slides a little smaller at the entrance than at the other end. The difference is very small, but there must be a difference, which can be ascertained by inspection or by cutting a piece of wood the length of the width of the slide and passing it along. Few photographers have tools or skill suitable for cutting hard mahogany, and it is seldom any are needed, except a small file or two and some fine glass-paper. The latter should be used very sparingly, as the glass gets embedded in the wood and soon wears out the slide. This can be partly avoided by gluing it on to pieces of wood of suitable shape.

The files should be "flat," and one of them thin enough to go into the groove. Files are harder than glass and won't bend very much; they should be used with discretion, both as regards themselves and the work to which they are put.

Stop removing wood before the slides go easily enough for working and apply an anti-friction preparation, made as follows:—Make or procure a stout cardboard box, about 1½ in. × 1 in. and ½ in. deep. Into it put spermaceti wax and warm gently on a hot plate. When melted, put in more wax until the box is quite full, making it as hot as possible without setting it or the house on fire, and let it cool. The wax can be applied to any part as required while still in the box. The wood may be warmed very slightly. Any fragments of wax should be rubbed off with a cloth (not fluffy). In doctoring up a sticky sliding part it is necessary to use a little brains, in addition to the articles mentioned, but if these hints are attended to no harm can result.—Yours faithfully,

C. Goodwin Norton.

DARK BACKGROUNDS.

To the Editors.

Gentlemen,—You speak in your editorial paragraph on "Dark Backgrounds" (page 121) of "a singular lack of depth" in modern examples of portraits taken against a black background, but is not this lack of depth to be praised and sought after rather than condemned? Dead black grounds are certainly not natural, and are most inartistic, as well as being difficult to print by some processes because of "bronzing." I dislike seeing a portrait head or figure stand out against a real "nothingness"—a "depth" such as you appear to advocate.

The best type of black or very dark background is surely that which can really be seen, and the most satisfactory method of getting a blackness of this description is to use a plastered wall

distempered black, or very nearly so. Properly lighted with a side, or even a top light, the roughness of the distempered ground catches a certain amount of light, and gives a body or a solidity which a suitable exposure will render on the negative. It is, I think, this "body"—a blackness one can see as being "something" behind the figure—we require, rather than a Stygian gloom none can fathom.

When a blackness is impenetrable, it is impossible to get a shadow upon it, but a shadow—and very often a helpful one to a composition—is easily obtained upon what may be called a visible blackness, i.e., one with a body, because of the possibility of getting something darker than the blackest "solid" by simply casting a shadow upon it. And the sitter—if placed near enough to the black background—can be made to cast a shadow that will often help a picture very considerably.—Yours faithfully,

GODFREY WILSON.

THE PROBLEM OF HALATION.

To the Editors.

Gentlemen,—One evening last week I happened to drop in at a photographic society's meeting, where I heard a capital lecture given by one of our best known trade lecturers, who dealt with lenses, exposure, development, halation, and many other things, using a blackboard and chalk to illustrate his remarks. Two of the sketches he used are enclosed.

Fig. 1 was used to illustrate the action of light upon a film, and the proportions of film and glass are, of course, exaggerated in order to make the points clear. F represents the film upon the glass G, and the "crystals" represent the silver in the film. The lecturer explained that in cases of under-exposure only the particles in the upper part of the film (A) were acted upon; if the exposure was correct, the light went deeper (say to B), while in cases of over-exposure light went all the way through (to C) and reached the glass, the silver being blackened by the developer accordingly. He used the well-known diagram (fig. 2) to explain halation, F being the film, G the glass, and L the ray of light from the lens which went through the film to the glass at the back, where it was reflected back again, and so caused halation, he recommending, of course, the use of backed plates, because of the danger of halation.

The amateurs in the audience were greatly interested, and asked several questions before the lecturer had to rush away to catch a train. After the meeting had closed, an amateur who had just started photography was seen to approach the board and carefully study the two diagrams. He was asked by an old hand what interested him and what his difficulty was—he looking so puzzled. His inquiry and criticism started a heated debate, as beginners' questions sometimes do.

"Judged and explained separately," said the tyro, "these two diagrams are quite all right, they explaining the points perfectly. They, however, are not in agreement, and, to my mind, quite contradictory. Assuming fig. 1 to be correct, light only reaches the glass when over-exposure is met with; therefore you can only get

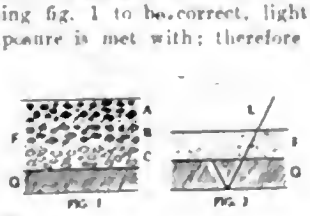

FIG. 1. FIG. 2.

halation when exposure has been excessive. By exposing correctly—or even a trifle more—the light-ray never reaches the glass, and cannot therefore cause halation. Why, then, over-exposure? If, as some say, you get the effect shown in fig. 2, whatever the exposure may be—under or correct—then fig. 1 cannot be correct."

The beginner's comments on the teacher's diagrams set me thinking, and I have done much more of it since reading your editorial paragraph (p. 106) on "Window Portraits," in which you say: "For such subjects backed plates or film should always be used. There is a natural tendency in such conditions (taking portraits with window background) to under-expose, with the result that the high lights are blocked up in the attempt to secure some trace of detail in the shadows, but this may be avoided if means are taken against halation; what is mistaken for over-exposure in a *properly-exposed plate is really halation*."

Assuming halation to be possible with a correct or fairly correct exposure, cannot such halation be stopped (on an unbacked plate) by developing in some particular way? I think—I might even say I know—it can; but how? I have, in the course of my thirty years' practical work, met many experienced photographers who scorn backed plates, and claim that by exposing and developing properly no halation need appear. And I believe it, after an experience I once had.

Twenty years ago I was making ready to start on the task of taking interiors of the most famous of the Italian picture galleries for one of the leading Parisian view-publishing firms, and when discussing apparatus, etc., with my chief, I asked for backed plates of a special make. "Backed plates!" he cried. "We have now twenty-one operators at work in various parts of the world, all engaged upon important tasks, and not one of them ever asks for or uses a backed plate. You give the correct exposures necessary, and return the plates to our developers to be developed; they'll see that no halation appears on the negatives." I did as requested, all exposed negatives being sent to headquarters for development, and no halation was to be found upon any of the negatives.

At intervals since that experience I have made many experiments to prevent halation by development, but have never been successful, and yet the many who I have heard say they can do it say that there is no secret. Obviously we have yet a lot to learn about halation.—Yours faithfully,

GODFREY WILSON.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 6-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

K. J. P.—For frame making appliances apply to Imperial Moulding Works, Macclesfield.

A. A. P.—The postcard is printed from a half-tone block. Cards of this kind can be supplied by Messrs. Hood and Co., Ltd., Sanbride Works, Middlesbrough.

R. P.—The best and neatest method is that described on page 448 of the current "Almanac," namely, of photographing the titles on a process plate and stripping them with hydrofluoric acid on to the negatives.

R. G. A.—The spots may be due to defective paper, but from their appearance under a magnifier it looks as though they may have been caused by air bells on the prints whilst in the fixing bath, due perhaps to overcrowding in this bath.

D. E.—Zinc, which the metal appears to be, does not last very well when used for developing solution, although it has a fairly long life as a washing tank. Unless you can get the earthenware tanks, the best thing in the long run is to have a tank well made of hard wood. Messrs. F. Brodrick, Ltd., 50, High Street, Bloomsbury, London, W.C. 2, is one firm which lays itself out for the making of such tanks.

H. K.—If the enlargement has been perfectly fixed, say in three successive hypo. baths, we think the process would be without harmful effect, either immediately or with lapse of time. But if the enlargement has not been thoroughly fixed (and papers nowadays are not so readily fixed as formerly), then we think the

process is liable to cause the appearance of silver stains, not perhaps immediately, but in course of time.

H. J.—A very good preparation for backing is made by mixing strong gum solution, about 1oz., with crystal caramel 1 oz., and finest lamp black (ground in the minimum quantity of water) about 2 ozs. To this is added about 2 fl. ozs. of alcohol, preferably pure spirits of wine, not methylated spirit. The crystal caramel is that made by Lichtenstein, of Silvertown, London, E., who supplies, we think, only in large quantities, but you could get a small lot from a firm such as Johnson's, of 23, Cross Street, Finsbury, London, E.C.2.

S H. G.—Of course it is possible that the comet-shaped markings are defects in the plate, but such are a rare defect of manufacture, and in other respects the plate certainly does not show evidence of being stale. Without knowing anything to the contrary, we should make a guess that these spots may have been caused by developer dust settling on the plates before exposure, or between exposure and development. Perhaps you can decide whether you find the markings appear at about the same time that you have been making up fresh developer.

D J.—(1) Brass fittings from the Photographic Supply Co., Shepherd's Lane, Leeds. (2) You do not say the size of the camera, nor whether hand or stand. Generally speaking, we should prefer to recommend the *f*/6 lens. (3) Messrs. Houghton's sell an excellent series of diaphragm shutters under the name of "Ilex," one or other of which should be suitable. (4) Negative attachments have long been supplied by optical firms, particularly Messrs. Dallmeyer, although the separate negative has largely gone out of fashion for telephoto work since complete telephoto lenses have been introduced.

C J. K.—Under present copyright law we have no doubt that the map would be regarded as an original work of yours, for it evidently includes indications and marks as well as notes which are not to be found on existing maps, and represent your own knowledge of the islands. In these circumstances we think it is a work entitled to copyright. There is no need whatever for you to register it or do anything in order to establish your copyright in it. Under the present Act that is assumed to be created automatically by the fact of your having produced the work "on your own," that is, without being paid by somebody else.

W. R. H.—You can buy sodium metal from scientific chemical merchants, such as British Drug Houses, Ltd., 22-30, Graham Stree , City Road, London, N.1. There are one or two small books on chemicals, *e.g.*, "Chemistry for Photographers," by C. F. Townsend, and "Photographic Chemicals," by W. Taylor, obtainable, if in print, from Messrs. Iliffe, 20, Tudor Street, London, E.C.4. But probably the best work for your purpose is a rather old book, namely, "Materia Photographica," by Clement J. Leaper, published in 1891. We see a copy of this is offered by Messrs. Sotheran, 140, Strand, London, W.C.2, price 2s.

B A.—(1) Plates for direct positives are supplied by the Magna Gelatine Plate Co., 2, Eastborough, Scarborough; by the Quta Co., 252, Haydons Road, Wimbledon, London, S.W.19; and by the Victoria Frame Co., 103, Anglesey Street, Lozells, Birmingham. (2) A formula for combined development and fixing is as follows :—

Water, to make	40 ozs. fluid.
Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo.	8 ozs.
Liq. ammonia, .880	2 fl. ozs.

Addition of more ammonia to the developer gives more vigour. The plates develop (and partly fix) in 2 or 3 minutes. They can then be examined by daylight and fixed in plain hypo.

D. M. A.—We can find very little fault with the portrait, which is a very nice piece of arrangement and lighting. If we have any criticism to make it is that the line of the shoulder and neck and the "sleeve" of the dress is rather hard. A firelight effect if this kind can do with being softer both as regards outline and contrast, and we think it is worth your while to print it in sepia (and perhaps stain the print to a pale orange colour), and also to introduce a certain amount of diffusion by means of thin celluloid between the negative and the paper. The background also seems to us to want a little relief, such as we judge from the print could easily be done on the glass side of the negative.

N. S.—(1) There have been a very great many different processes of reversal—that is to say, conversion of a negative image into a positive. In the "B.J." of November 17, 1916, we gave the working details for a few of the best of these processes which have been brought out within the last ten years or so. But really none of these methods are thoroughly practical for regular use in comparison with the making of a negative and the printing of a positive on paper or glass from it. (2) The tiny photographs were made in some cases by wet collodion, but we believe the best (made in Paris) were done by a form of albumen process. The latter has gone out of use, although we believe the little photographs are still to be obtained in Paris through a trade house in touch with the few craftsmen doing this work. As regards the albumen process, about the best reference we can give you is to a paper by Miethe, describing working details, which appeared in the "B.J." of September 13, 1912. We have not these old issues in print, but very likely you could see it in your public library.

R A.—(1) You can get several patterns of printing box for use with oil light from Butcher, Kodak, or Marion, as well as from other makers, and for printing on bromide the oil light, which has to be reflected from a mirror in the printing box, is powerful enough in ordinary circumstances, that is to say, unless you are dealing with negatives of heavy density. But for printing on gaslight and for dense negatives on bromide the best plan is to use daylight, by fixing the printer to an aperture in a shutter which is mounted in the window preferably of a room which receives a north light. The exposure would then require to be made by a sliding panel outside or by a shutter placed inside the printing box in the pattern of a pair of opening flaps. As you do not tell us the sizes of negatives we cannot suggest any dimensions, but, generally speaking, any commercial box could be adapted for use in daylight. (2) As regards artificial light in the studio, the only recourse is to a battery of incandescent gas mantles, sold by Griffins as the "Howellite." It is fairly satisfactory, but it gives out a good deal of heat, and if the studio is small and not very well ventilated, may make the place unbearably hot in the summer. Nevertheless, unless you are ready to fit up a chamber for flashlight it is the best thing you can have.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3176. Vol. LXVIII. FRIDAY, MARCH 18, 1921. Price Fourpence.

Contents.

SUMMARY.

In consequence of the Easter holidays the "B.J." will be published a day earlier next week, and, therefore, line advertisements for insertion in next week's issue (March 25) must reach our publishers not later than 12 (noon) on Tuesday next, March 22.

In a leading article we draw attention to some of the æsthetic amenities which require to be observed if photographs from the air are worthily to take their place with those from the ground level. In the case of aerial cinematography, the obstacles to securing a film with the necessary movement in it appear almost insuperable. (P. 150.)

In a recent paper before the Royal Photographic Society, Mr Julius Rheinberg described much interesting experimental work of his in the field of applying the changes in the physical properties of colloid substances to photographic processes. (P. 153.)

The prices of dry-plates were reduced by about 18 per cent. as from Monday last. On page 160 we print a table tracing the fluctuations in price since the disappearance of the popular shilling standard a year or two before the war.

The unconventional in lighting is among the little explored present-day possibilities of portrait photography. A doorway opening upon a sunlit garden provides opportunities for some exceedingly fine lighting effects. (P. 150.)

In reference to Mr. Willis's article on the *de luxe* printing processes, one correspondent emphasises their advantage from the standpoint of hygiene, and another questions the alleged difficulty of obtaining printers. (P. 162.)

Mr. W. Thomas, in a tribute to the usefulness of the phenosafranine process of desensitising, expresses his preference for working by a bright yellow or red light rather than by a very much weaker white light. (P. 151.)

Mr. A. Thomas describes a useful fitment for the enlarging easel consisting of a frame provided with a series of flap shutters. The frame can be pinned in front of a test strip of paper, and successive trial exposure very quickly made. (P. 161.)

At the South Suburban Photographic Society a youthful experimenter gave an excellent demonstration of the preparation and use of Kallitype paper. (P. 160.)

A hint on the making-up of the very useful single solution mercuric-iodide intensifier is given in a paragraph on page 150.

The usefulness of adding an even tone to a print by "sunning down" is of service chiefly with print-out papers, but can be usefully applied to development papers. (P. 150.)

A recent patent specification of Mr. Harold Hood's describes an improved mounting of half-tone blocks, providing greater security of the metal, and allowing of type being set closer to the printed impression in consequence of the narrower width of the "beard" of the block. (P. 157.)

In photography, and particularly in cinematography, there is still the need of a better knowledge of underlying principles. (P. 149.)

EX CATHEDRA.

Plate Prices Reduced. Photographers everywhere will receive with much satisfaction the announcement on Monday last of a reduction in the price of dry-plates. On another page we print a table showing the present reduction in relation to the successive fluctuations in price since 1913. The degree of the present decrease varies within narrow limits in the different sizes, but taking half-plates as a standard of comparison the reduction from 7s. 4d. to 6s. is just over 18 per cent. This reduction brings prices to the level at which they stood from February 5 to August 1, 1918, and makes the present price exactly 2 1-5 times that prevailing at the outbreak of war. We see that French dry-plates have also been reduced in price 10 per cent., and the advice received from one plate-maker in this country announces also a reduction in the price of development and print-out post-cards. This declension of the abnormally high prices of sensitive material will certainly be received as an encouraging and stimulating fact in all sections of the photographic trade, and will do much to restore activity in certain branches.

* * *

Technics. Despite the great volume of information contained in books and periodicals which deals with the underlying principles of photographic processes, we fear it must be admitted that photographers as a body have little inclination to look below the surface at the causes which are inherently associated with practice. Much less are they inclined to apply such of those principles as are susceptible of numerical expression to the control of photographic operations. Probably there are not many in the mental state of a studio photographer who had purchased a lens much too large for his working space and returned it to the seller with the complaint that it had no focal length. Nevertheless, an acquaintance with the more elementary optical and chemical principles which in great measure are a helpful guide to practical work and are reasonably comprehensible is, we are afraid, the possession of few. Perhaps some consolation may be derived from the fact, as we believe it to be, that in the allied cinematograph craft the average acquaintance with the technics of the subject is at an even lower level. We had two instances of this recently. A specially-skilled projection operator, the pick of the firm's staff, was sent to fit a new lens which had been purchased for a theatre, and in default of a proper mounting for it, thought it sufficient to extemporise a holder for the objective, which actually left it free to wobble when the machine was working. The other instance, which is mentioned to us by a correspondent, is that of two projection operators with whom a discussion was held on a means for increasing the period of time during which each picture, whilst stationary, is illuminated on the screen. Neither of these operators could see any useful purpose in such an inquiry, for, said they, the film never does stop. How could it,

when we are turning the handle all the time! Evidently there is still a field for the labours of the technical writers in our cinematograph contemporaries.

* * *

Unconventional Lighting The average studio operator is apt to become more or less stereotyped in his method of lighting, and thus often misses an excellent effect, because the sitter is not at the moment in the regulation position. It is a good plan to keep the eyes open for striking effects of light, whether in the studio or elsewhere. The rapidity of gelatine plates has increased to such an extent that exposures can be made under conditions which even a couple of years ago would have been fatal to success. It is quite a mistake to suppose that only a hard result can be obtained from a strongly-lighted subject. We know of one photographer at least who obtained excellent portraits of children, and sometimes women, by posing them in an open doorway leading into his garden in full sunlight. Correct exposure and judicious development reproduced the lighting as it appeared to the eye, and did not yield the "soot and whitewash" effect which is usually associated with direct sunlight pictures.

* * *

Mercuric Iodide. The mercuric-iodide intensifier is gradually growing in favour, and will in time probably oust the old favourite mercury and ammonia altogether. As we have already given formula and working instructions, it is not necessary to repeat them, but there is a little point which deserves attention in compounding the solution. It was first raised by Mr. Welborne Piper, and is, in our opinion, of some importance. It is, that the mercuric iodide should be made by pouring a solution of mercuric chloride into one of potassium iodide, and not *vice versâ*. Also it is preferable to clear the solution by using a few drops or a small crystal of potassium iodide instead of the hypo usually recommended. Although a trace of hypo in the negatives to be intensified does not interfere with the process, it has a tendency to convert a portion of the mercuric iodide in solution into an inert salt and so to waste it. It is not perhaps generally known that after well washing a negative treated with mercuric iodide may be further strengthened by treating with amidol, as is done in chromium intensification.

* * *

Sunning Down. Many photographers are not aware of the fact that a much better effect may be obtained when printing from harsh negatives by giving the paper a short exposure to light out of contact with the negative after it has been taken from the frame or printing box. This is of particular value when dealing with over-dense negatives that tend to give blank expanses of white paper, such as the sky portion of a landscape. When printing upon one of the daylight papers the extent of the light-action is readily observed and controlled, but even with development papers much better results may be sometimes obtained through the means indicated above. Care must be taken not to allow the action to go too far, or the effect of the attempted cure will be worse than the original defect. Very little exposure only is needed, and it should be so adjusted that its effect is hardly visible. This "sunning down," as it used to be called, may be general, or its action may be controlled locally according to requirements. If only a little depth of tone is needed, as in the case of the sky in a landscape negative, the action of the light may be regulated in the following simple way, though this applies only to print-out papers. The exposed print is replaced in the printing frame and a piece of thick opaque paper, slightly larger than the print, is taken and torn roughly to form a mask to serve in protecting those portions of the print where no light-action is required. The frame is then taken out into the light and the mask rapidly moved over the print while the paper is allowed to darken, the movement preventing the formation of a harsh line. This method is not, of course, confined to landscape subjects, though it is among these that it is found most generally useful.

LIMITATIONS OF AIR PHOTOGRAPHY.

When in the summer of 1839 the great French *savant* Arago communicated to the Academy of Sciences the working details of the Daguerreotype process the Parisian public became rapturously excited, and the artists in particular were filled with generous enthusiasm. Paul Delaroche, for instance, having obtained a Daguerreotype from the inventor, exhibited it everywhere, exclaiming, "Painting is dead from this day!"—an observation which succeeding generations of artists and art critics have done their best to make the world forget. The incident is instructive as an example of the doubtful perspective in which new ideas are commonly viewed, and something may, perhaps, be learnt from it in connection with the art of aerial photography, now in its childhood, and giving promise of a healthy adolescence. In a good many quarters the tendency has been to exaggerate the importance of this new departure quite outside its importance from the military standpoint, and as an aid to surveying and exploration. A useful corrective to this tendency is a visit to some such exhibition as the "Travelogue" of the Ross-Smith flight from England to Australia, now "showing" at the Philharmonic Hall in Great Portland Street. It is quite an interesting performance, and some of the photographs taken from the air, notably those of the Alps, are of distinct merit. But it is quickly realised that, if these had not been supplemented by pictures obtained on what aviators call "the floor," mostly during the return journey, the photographic record would have been disappointing, even if time conditions had enabled a much fuller series of exposures to be made.

In particular, aerial cinematography leaves a good deal more to the imagination than the average spectator likes, unless it is carried out under specially favourable conditions. Flying low over an area in which there is a certain amount of life, or a succession of strongly marked features, a film may doubtless be secured by a shrewd operator, which will show well on the screen and keep an audience interested for a few minutes. But, ordinarily speaking, a cinematograph record from a considerable altitude is, not to put a fine point on it, hopelessly dull, even more so in fact than the average run of films made up of exposures from a moving train. This is hardly surprising, in view of the distance from "the floor," and the extensive area included in the view-angle of a short-focus lens. The desideratum in cinematography, namely, a sequence, as far as possible unbroken, of actions, movements, gestures, processes, or scenes peremptorily arresting the spectator's attention, is wholly lacking in a film in which even objects of magnitude, such as a great camp or mosque, are so insignificant that they hardly relieve the general monotony.

It goes without saying that some very fine single photographs have been made from aeroplanes and airships, and in this direction a good deal of success should be achieved in the future. But even skilled operators have probably a good deal to learn in this connection, and it may well be that in the course of the next few years some important improvements will be introduced in the apparatus employed in aerial work. As things are, it is only

occasionally that a photograph from the air is at all satisfying, and very frequently indeed it is frankly hideous. There is no reason why it should not be in its way a work of some artistic merit, for many a fine picture has been drawn or painted from a very elevated standpoint. But no artist, of course, would attempt a sketch from an eminence if he had to look down at the angle at which some aerial photographers seem to delight in taking their "pictures." There is plenty of room in this respect for improvement, and no obstacle to progress in the way of deficient optical equipment. Perhaps a useful guide to the operator would be an attachment to the camera showing graphically and conveniently the extent to which the camera was being tilted during exposure, and in not a few cases a record of the tilt would be an interesting aid to the study of the resulting air photograph.

These few observations only touch, of course, the fringe of a large subject, but we have said enough, perhaps, to make it clear that for many years aerial photography is not likely to be a serious rival to photography on the ground, except for the particular purposes for which it is invaluable. Some day, possibly, when we all spend a large proportion of our time in the air, there will be a general demand for pictures as seen aerially from considerable altitudes, and the most ordinary form of full-length portrait will be of a "sitter" in his or her private aeroplane, the latter, of course, being "snapped" in motion. Aerial "studios" in such circumstances will be rather serious problems, and one imagines that double-printing will usually have to be resorted to in the matter of backgrounds. Cloud-studies for this particular purpose will no doubt be forthcoming in great variety and at moderate prices, but there will always be clients dissatisfied with such simple aids to pictorial effect, and more inclined to favour, say, the Parthenon or Vesuvius in eruption as a suitable "setting." Those will be days when anything not seen from a more or less sublime standpoint will appear comparatively strange to a race spending, maybe, a great deal more time in aeroplanes and airships than we do in railways and buses. But the restless prospect thus indicated should be—let us hope it is—fairly remote, and in the meantime there is no need to imitate the premature pæan of Arago on the Daguerreotype, and to imagine that photography on *terra firma* is seriously menaced, whether as a profession or a recreation, by photography from the clouds. Coincidently, it would be well if air photographers took more careful stock of their limitations, and endeavoured to gain fuller advantage from their exceptional opportunities by approximating their renderings to the requirements of ordinary human vision. Some results recently printed in "The Times" show progress in the right direction, and it should not be long before we see the last of photographs taken with the camera held vertically, and similar freaks, which, except for reconnaissance and survey purposes, have no real interest or value.

THE NEW WONDER WORKER.

It looks very much as if the newly-introduced desensitiser will prove one of the greatest boons possible to those photographers who, either from choice or force of circumstances, use panchromatic plates. Particularly now that the speed of this class of plate has been almost doubled by at least two makers of them, the extreme care needed to protect them from light-action, when handling in the dark-room, has become still more necessary.

Having used panchromatic plates constantly since Messrs. Wratten first introduced them to the photographic world, it has become, from practice, quite simple to handle them in complete darkness, and in the ordinary way it is when removing the negatives from the fixing bath for washing that they the *seen* for the first time.

This, when exposures given had been correct, proves quite satisfactory, and usually good negatives are the result; it certainly gets rid of fogged negatives, but there is an entire lack of that interest felt when one can watch the progress of development, from time to time, under a flood of safelight, such as is employed in using slow ordinary plates.

This working in complete darkness, or a condition which at best can only be described as darkness made visible, has doubtless been one of the prime causes which prevented all but a comparatively small number of photographers using panchromatic plates, but this should now be a thing of the past, since by the introduction of their "Desensitol" (to give it its trade name) the Ilford Company have simplified the use of all these delicate colour-sensitive plates to such an extent that, except for first soaking the exposed plate for one or two minutes in the solution in *complete darkness*, all the rest—developing and fixing—can be done safely with such a flood of red or orange light as would normally only be used for slow negative plates.

The manufacturers state that after the plates have been given the required time in the Desensitol bath, all that follows may be done safely in *white light* under certain conditions. Personally I fail to find this method gives such clean negatives as when a safe screen is used in the lantern. Certainly that is so when very rapid plates or the panchromatics have been tried, and really it seems difficult to imagine what magic benefit is to follow using a weak white light in preference to a pale red or bright orange one. The object in either case is to be able to see the progress of development, for which purpose one form of light is as effective as another of similar intensity. As the result of a series of experiments made with different plates, and after desensitising, developing some under reflected white light, and for others using different safelights, the following has been found the most convenient procedure when the fastest panchromatic plates are being handled and perfectly clean negatives desired.

All dark-slides are filled in complete darkness, quite a simple performance after a little practice. When about to start developing, a dish of the Desensitol, ½ oz. to 25 ozs. of water, is put on a corner of the table, and when ready the lamp is switched off, and, in complete darkness, the first plate is slid into the solution and left there for a couple of minutes. Then the lamp, with a No. 1 Wratten safelight, is switched on again, and from this point all the rest may be done safely, just as if handling a slow ordinary plate. But here again there seems no particular advantage in leaving the plate uncovered all the time. Therefore, after flowing on the developer, I cover the dish for one or two minutes, then take out the plate and clean off the black backing. I return the plate to continue development, and when it seems finished rinse and put it to fix.

The comfort of doing all this in a room flooded with bright red light is obvious, as is also the lesser risk of damaging the wet, tender film when passing the plates from one tray to another.

The solution being of a deep intense red colour, it is as well to abstain from dabbling about in it with one's fingers, which seem to absorb it with avidity and to part with its

results as reluctantly. As walking about with red-stained finger-tips is not pleasant, a little care in handling the plates is advisable in order to avoid this.

The negatives themselves are all stained red, but this clears away during washing, though some plates seem to hold the dye longer than others, and it is better therefore to follow the Ilford instructions and bathe the negatives in a clearing bath made up of hydrochloric acid, 4 parts; alum, 2 parts; water, 100 parts; then washing as usual for a short time. This is a simple and effective way of discharging all trace of colour, for the negatives become crystal clear, and it takes but a few minutes to accomplish.

It is a wonder worker, this Desensitol, for it transforms the handling of extremely rapid and colour-sensitive plates from a work of some difficulty to one of ease and certainty, and does away with all risk of light-fog during development.

There is another matter which, at times, gives rise to trouble when using plates of such extreme sensitiveness as to require handling in complete darkness or the deepest of ruby or green safelight in the dark-room lamp, and *especially when a quick-acting developer is used*. Unless the solution is flowed evenly and quickly over the entire plate in one sweep it is likely to produce markings, more or less pronounced, on the resulting negative, which requires some amount of dodging when printing is done, or even ruins the plate for this purpose. The larger the size of plate, the more easily may this trouble arise; the preliminary soaking of exposed plates in this desensitiser gets rid of all risk of trouble from uneven flowing on of developer, for the whole proceeding is done in a flood of safe light, and trouble from markings and air bubbles becomes a thing of the past.

It will prove itself a boon and blessing to all photographers, but to none more than those of us who pin their faith, in all critical work, to the fast panchromatic plate.

W. Thomas.

THE POINT TO FOCUS ON.

It is often stated that depth of field in focus depends only on the diameter of the aperture, and is independent of the length of focus of the lens used. While this statement is correct, it requires to be qualified by the remark that the print taken with a lens of short focus must have been enlarged to the same size, as the print taken with a lens of long focus.

The alignment chart, fig. 1, enables us to solve the problems of depth of field in focus (usually called "depth of focus") in an elegant and simple manner. Having decided the distances, measured in feet, of the remote and nearer objects which are desired to be "sharp," draw a straight line between the two corresponding points on the left-hand scales headed "Remote" and "Nearer," and continue this line to meet

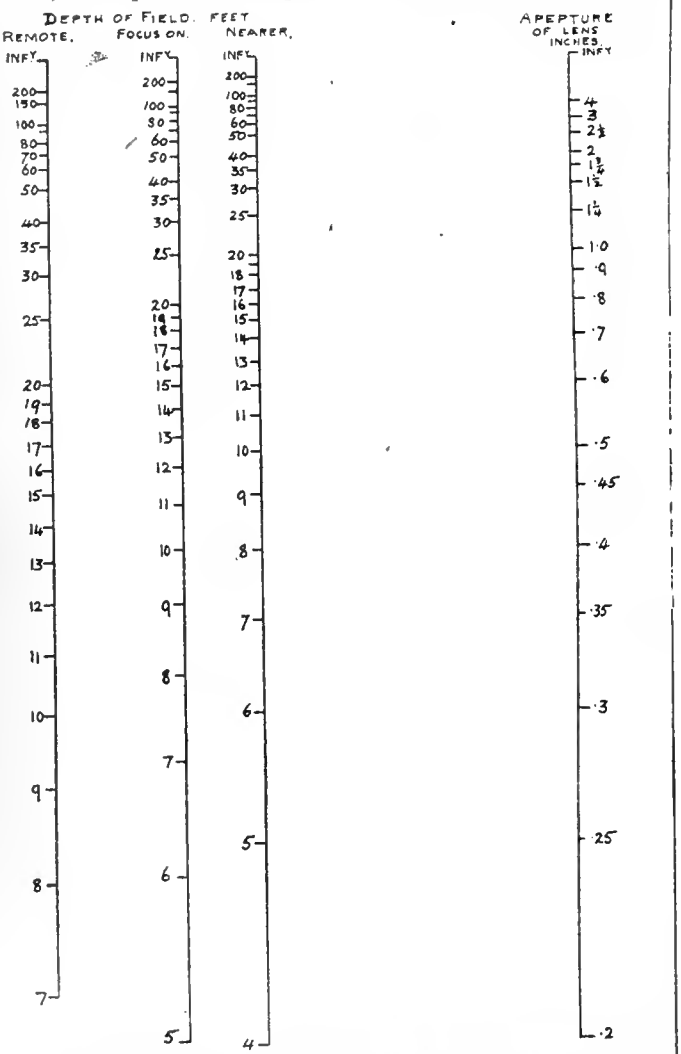

Fig. 1.—Chart showing actual diameter of lens diaphragm for maximum depth of focus of near and distant objects at given distances: also showing point to focus on.

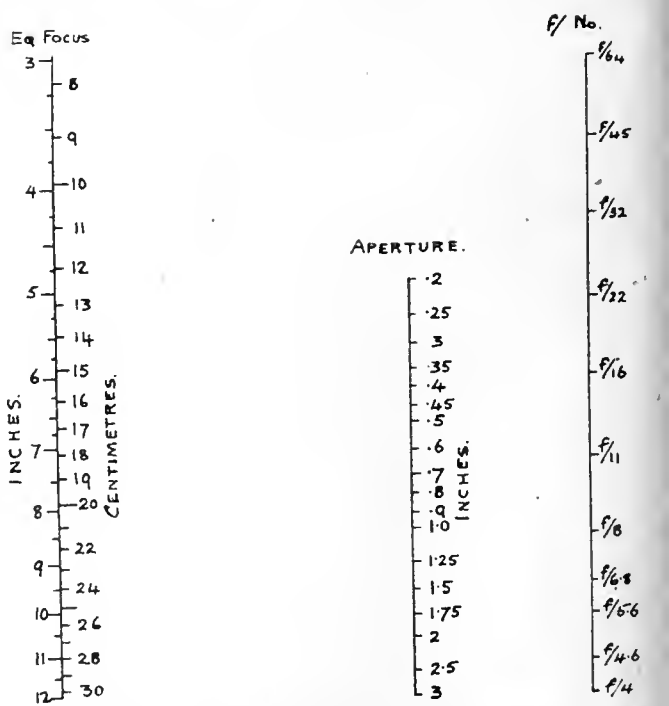

Fig. 2.—Chart showing actual diameters of diaphragms corresponding with various conjunctions of focal length and *f* No.

the right-hand scale headed "Aperture of lens." This last-found point will be the diameter of the aperture in inches, to which the lens must be set. The line just drawn will also cross the middle of the three right-hand scales headed "Focus on," and the point where it does so will indicate the distance on which the camera must be focussed in order that the remote and nearer points may be equally sharp.

It will be objected that the diameter of the aperture is not

marked in inches, but only by *f*/ numbers. Fig. 2 enables the diameter of any stop to be found. The left-hand scale is graduated to represent equivalent foci between 3 inches and 12 inches, with corresponding values in centimetres. The right-hand scale is graduated from *f*/4 to *f*/64 with the usual intermediate apertures, and the centre scale is gradnated to indicate diameter of the aperture in inches. Straight lines from the point representing the equivalent focus of the lens proposed to be used to the points representing the *f*/ numbers will determine by their intersections on the centre scale the diameters in inches of these stops

For convenience of use, these values for lenses in constant use should be marked off on fig. 1 so as to avoid reference to fig. 2 on each occasion.

The circle of confusion on which the design of fig. 1 is based is taken as being 1/1200 of the actual focus of the lens, which is conjugate to the distance focussed on. This means that, using a lens of 12-inch focus, the circle of confusion is 1/100 inch, which is usually considered as a standard, while with a 6-inch lens the circle of confusion is 1/200 inch, and so on, in proportion. If it is desired to work with a larger circle of confusion, the diameter of the aperture should be increased proportionately; if with smaller circle of confusion, the aperture must be decreased. For example, the lens to be used is of 6-inch focus, the remote object is 30 feet away and the nearer object is 12 feet away. Fig. 1 shows that an aperture of .4-inch must be used, and that we must focus upon an object 17 feet away. Using fig. 2, we find that *f*/16 nearly equals .4-inch aperture for a 6-inch lens. Therefore, if the photograph is to be enlarged two diameters and not appear fuzzy when viewed at a distance of 12 inches, the stop just found must be used. If, however ,a contact print only is going to be made, the circle of confusion can be 1/100 inch diameter; that is, twice as large as the designed circle of confusion, and we can therefore use an aperture twice the diameter, or *f*/8 instead of *f* 16.

The formula, on which fig. 1 is based, and which gives the relations between the distance focussed on, the remote and nearer points in focus, the diameter of the aperture, and the circle of confusion, is:—

$$\frac{1}{F} = \frac{1}{N} - \frac{1}{x \times A} = \frac{1}{R} + \frac{1}{x \times A}$$

in which—

F is the distance of the point focussed on.

N is the distance of the nearer point.

R is the distance of the remote point.

x is the ratio of the back focus of the lens (which is conjugate to F) to the diameter of the circle of confusion. In fig. 1 this ratio is 1200.

A is the diameter of the aperture (entrance pupil) of the lens.

Care should be taken when using this formula to keep the quantities F, R, N and A in the same units of length.

Those who take a pleasure in deriving these formulæ for themselves are referred to the eleventh Traill Taylor lecture, that by Dr. E. Wandersleb on "The Regulation of the Rays in Photographic Objectives," which was published in the "B.J." for February 12 and 19 of 1909 (Vol. LVI.), p.p. 116 and 139. They should ponder over the significance of fig. 14 (p. 122).

R. Savory.

SOME NEW DIRECTIONS FOR PHOTOGRAPHIC RESEARCH.

(A paper read before the Royal Photographic Society, and reprinted from the Society's Journal.)

Photography as we know it originated with the observation of the fact that the action of light produced chemical alterations in a light-sensitive film, and it is not unnatural, therefore, that the study of photography and photographic processes has in the main been the study of making use of these chemical changes to best advantage. Research on the preparation of emulsions, developers, toning and fixing agents, and the methods of using them, has been chiefly concerned with the utilisation of the *chemical* changes by light on the light-sensitive film and turning it to best account to obtain the desired results.

The *chemical* action of light on the photographic film, however, is nearly always accompanied by some *physical* change in the colloid vehicle also, or perhaps it would be more correct to say that it is invariably accompanied by some such physical change. The physical changes may be of various kinds, and not being usually very pronounced, this side of the subject appears to me to have perhaps received less attention than it deserves. I propose this evening, therefore, to bring to your notice some observations and results obtained in investigations which I have carried out at various times for specific purposes, showing how these physical changes in a photographic film, which accompany the chemical changes brought about by the action of light, may be made use of in new ways. I am hopeful that this may stimulate discussion, and serve to show that it points to new fields of inquiry worth following up in other directions.

A few instances of marked physical changes in a film accompanying the action of light are familiar to everyone present: they have been known for a very long time, and have been exploited in various practical photographic processes. Perhaps the most familiar instance is that of the action of light on gelatine or albumen containing the proper amount of potassium bichromate. The bichromated gelatine becomes insoluble when acted on by the light, and the portion not acted upon remains soluble and may be washed away, and there are various important processes dependent on this fact. Although in this case the whole nature of the sensitised film has been physically changed by the action of light concomitantly with the chemical change that has occurred, attention would not usually be focussed on this physical alteration, as I suppose that questions of solubility and non-solubility would usually be regarded rather from the view-point of chemical change.

A more pronounced case of physical change is afforded by the instance of the difference in the swelling properties of photo-sensitive gelatine films, the reliefs so obtained having been exploited for various photo-mechanical processes.

Again, certain processes, as instanced by collotype, have been founded on the differential adhesive power of the exposed and unexposed parts of bichromated gelatine films, the differential adhesiveness for greasy substances being itself dependent on the differential power of absorbing moisture of the exposed and unexposed parts.

Lastly, it has been found that by chemically treating exposed films, the exposed and unexposed portions may be made to absorb certain dyes selectively, and certain processes have been founded on this fact. This, however, again would probably be regarded rather from the chemical than from the physical standpoint.

So far as I am aware, the instances named illustrate the chief directions in which the physical alterations caused by the action of light on photographic films have so far been utilised, although very likely some other ways may be pointed out by members present, in the discussion.

I now come to a different way in which the physical properties of a photographic film may be markedly affected by the action of light accompanying chemical change. It is a way I set out to obtain, and was successful in obtaining and utilising in researches on a new method of colour photography, to which I devoted several years' experimenting just prior to the outbreak of war.

Without entering into any special details of this process of colour photography itself, I need only say that one of the problems that presented itself in connection with the same was how to obtain three-colour line or dot screens, somewhat similar to the Paget screens, from which the colour lines or dots might subsequently be selectively extracted, *e.g.*, the red dots might need to be extracted wholly, the green dots partially extracted, the violet dots left in, and this selective extraction would require to be brought about at the same time by immersion in a single bath. Now, I was unable to make use of the Paget plates themselves, or rather I should say of plates made by the Paget process, because this process depends on coating the collodion, which is the vehicle of the coloured dots, with a photographic resist of bichromated albumen. The Paget process of screen making, as is known, is to expose the collodion film covered with the bichromated albumen resist under a dot screen, then wash away the unexposed parts of the resist, and the collodion on immersion in a dye solution is then dyed up selectively where the unexposed film has been washed away, leaving the collodion free, but is protected from taking up the dye, under the exposed dots of the resist, because these form an insoluble protecting surface. In the final Paget screen plate, of course, the dots in two of the three colours have this transparent insoluble bichromated albumen resist left upon them, and that was fatal for my special purpose. Naturally, I first tried by all sorts of ways whether it was not possible to get rid of the bichromated resist which remained on, but was not successful. I then went on the tack of trying to find some sensitiser for the resist, other than a bichromate: one by which insoluble resist dots might be obtained temporarily which could be converted into soluble ones subsequently and then washed away. On this tack I was also unsuccessful; moreover, I found that the washing away of the soluble part of the resist, so as to leave nice, clean, insoluble dots, was not quite such a simple thing as it reads. I then conceived the idea, Why not attempt to dye up or extract dye from the colloid vehicle, right through the superimposed resist film? This idea seemed attainable provided the permeability of the resist film to the solvent of the dye could be changed by the action of light, whilst the resist film remained soluble, whether exposed to light or not, in some other solvent which would not affect the underlying vehicle of the colour dots.

This problem, after innumerable trials, was not only successfully solved, but solved in quite a number of different ways, using various colloids as the vehicle for the colour screen and the resist. It will probably serve to make matters clearer if I describe in detail a specific case.

A plate was first coated with a collodion film dyed red, for example. This was coated with a photographic resist made up as follows:—

Gum arabic—I part in 5 of water ...	1 volume.
Green ferric ammonium citrate—I part in 2 of water	1 volume.
Uranium nitrate—I part in 2 of water	1 volume.

This resist is entirely impermeable to alcohol (industrial spirits) acidified with a few drops of HCl in the unexposed state, but after the action of light on it, it becomes permeable to the spirits.

If, therefore, the plate is exposed for a few minutes to light under a line screen, consisting, say, of 200 opaque and 200 clear lines per inch, and subsequently immersed a few seconds in the acidified alcohol, the whole of the red dye is extracted right through the gum resist, under the lines exposed to light, and a screen consisting of 200 red lines and 200 white lines per inch results.

Next, the plate is immersed in an alcoholic solution of green dye, and the white lines are then dyed up green through the resist. The plate then consists of 200 red and 200 green lines per inch.

Next, the plate is immersed in water, which washes away the whole of the resist, and it is coated with fresh gum resist as before. It is again exposed to light under a line screen; this time a line screen of 200 per inch with the opaque lines double as wide as the clear lines is used, and this screen is placed with the lines at right angles to the red and green lines already on the plate.

It is then again immersed a few moments in acidified alcohol, extracting the dyes from the collodion, corresponding to the clear lines of the line screen, and then immersed in an alcoholic solution of a violet dye, which dyes these clear lines up.

Lastly, the plate is again immersed in water, which at once dissolves and washes away the gum resist.

The final result is then a plate with violet lines, and red and green rectangles, all three colours occupying an equal area of the plate.

A few specimens of screen plates of the pattern described and of other patterns which were made by this process in 1913-14 by myself and Mr. G. C. Laws, who was assisting me at that time, are exhibited this evening. The process, I may say, is patented so far as screen plates are concerned, but has not been offered anywhere, and if any enterprising firm wishes to take it up and will communicate with me, I shall be delighted.

However, to revert to my subject. In the method described with the gum resist, the resist was washed away after the underlying collodion film had been dyed up in two colours, and a second resist applied before proceeding to re-expose and extracting the dye and then dying up in the third colour. But gum arabic is by no means the only colloid that can be employed for the photographic resist film. Fish glue could also be used, likewise albumen, and when employing albumen it was even found possible to leave the albumen coating intact after the first dyeing up, simply washing out the water-soluble chemicals in the resist, and sensitising it again by immersion in water containing 7½ per cent. green ferric ammonium citrate and 7½ per cent. uranium nitrate, and then proceeding with the process as described. This perhaps brings home more than anything else that it is purely a case of utilising the physical properties of the colloid film to bring about the desired result.

It will be seen that when once the general principal of the idea is grasped it is simply a matter of time and patience to work out all sorts of variations, so long as a few main conditions are borne in mind. These are simply:—

(1) The colloids of which the upper and underlying film consist should be of a different nature; for example, the one should be water-soluble, the other spirit-soluble, or soluble in some other solvent or mixture of solvents.

(2) The solvent chosen for conveying or extracting material from the underlying film must be one which does not harmfully affect the upper film.

(3) The light-sensitive chemicals in the upper film must be such that only the unexposed parts or the exposed parts, as the case may be, are affected by this solvent, or at all events the action must be very differential on the exposed and unexposed parts.

(4) The solvent for removing the upper film or light-sensitive chemicals must be one which does not affect the underlying film, or dyes or materials in it.

The general idea of action on an underlying material through a superimposed resist is one which I doubt not is capable of extension in quite a number of directions. I will instance one application of it to quite a different problem than the one already referred to.

Shortly after the outbreak of the war I had, unfortunately, to give up my experiments in colour photography, as Professor Cheshire, of the Ministry of Munitions, asked me to

see what could be done in the way of devising some good process for the production of "Graticules" (which, as most of my audience know, are the glass discs or scales with extremely fine lines on them, used in military and other sighting instruments). It was an urgent problem, since we had been chiefly dependent on Germany for these products, and, except for some very primitive methods, not at all suitable to mass production, the processes, monopolised by one or two German firms, were kept secret.

Some photographic method appeared to be the only feasible one, and, after first attempting a dyeing-up method which, it was quickly seen, offered no prospects of success, I decided to attempt an etching method, based upon the idea of differential action through a resist, which was subsequently to be washed away. The principle was, of course, just the same as in the previously described method, but the factors were much changed, because now the underlying film was the glass itself, and the solvent to act on the underlying film would no longer be a fluid, but hydrofluoric acid gas. I need not dilate at length on the matter; suffice it to say that after a great many experiments it was found perfectly possible to apply the principle.

In this case it turned out that the most suitable upper resist film was collodion containing an iron salt, and subsequently sensitised in an alcoholic solution of silver nitrate. A few specimens, prepared by myself or Mr. J. W. Purkis, who was acting as my assistant at the time, are exhibited this evening. Results were also obtained with water-soluble resist films on albumen, fish glue and gum arabic, but for the purpose in question the collodion resist gave the best results.

Now, it is quite true that these graticules were not eventually used, because, firstly, it was found impossible to get the resist so perfect as to prevent some microscopic pits on the surface of the glass, where they were not wanted; secondly, because the nature of the etched lines did not meet the optical desiderata; and thirdly, because very shortly after these experiments all desiderata were fulfilled by the method of grainless photography, examples of which I had the pleasure of exhibiting at the Society's annual exhibition. That, however, does not alter the fact that the principle of etching in this way has been found quite workable, and, for aught I know, might usefully be applied to work of a less delicate and exacting description than that demanded by graticules.

The last matter to which I will refer this evening is the different physical properties of colloid films according to the solvents with which they have been produced, and with which they may be treated. From the theoretical standpoint there is little, if anything, new in what I have to say: it is the practical applications which I wish more particularly to refer to, because I venture to think that certain simple fundamental facts, often very helpful in dealing with photographic problems, are not infrequently apt to be overlooked.

Now, the physical properties of the film resulting from a colloid in solution depend, amongst other things, on the rate of evaporation of the solvent or solvents, as well as on temperature. When two solvents which evaporate at varying rates are employed together, the resulting film has a tendency to be deposited in a more irregular manner than when it is evaporated from a single solvent. This principle is occasionally made use of in producing matt screens with fine grains or particles in the colloid varnish: the greater or less regularity of distribution of the grains of which the film is formed can be regulated by varying the two solvents and varying the ratio of one to the other. Another point is that thick colloidal solutions with two such solvents do not flow so smoothly or easily as solutions of similar concentration in which a single solvent is used; they tend to form ripples, or thicker and thinner places. Now, that is just one of the difficulties which occurs with collodion, which for photographic purposes is almost invariably made by dissolving the pyroxyline in a mixture of ether and ethyl alcohol, neither of which separately will dissolve it. Further, the considerable difference in the rate of evaporation of the ether and alcohol also varies with difference in temperature, and it is well known that the proportions used are different in winter to summer. And the resultant film has varying degrees of density or porosity according to the ratio of the solvents. To coat plates by hand with such collodion mixtures is an art. It can, of course, be done, and done very perfectly; for example, I had reason to admire Mr. G. C. Laws' adeptness at such work. But, personally, I could never coat a plate properly with ordinary collodion.

It is now seven or eight years ago that it seemed to me very desirable to find another way of making collodion for photographic work, either with a single solvent, or at least with two solvents having a much smaller difference in the rate of evaporation than ether and ethyl alcohol. A suitable single solvent was found in the use of pure methyl alcohol, which will by itself dissolve celloidin, or any of the usual photographic forms of pyroxyline. The collodion film formed by such a solution is, however, slightly opalescent, showing that the structure is comparatively coarse, that it is very porous and not as dense, therefore, as ordinary ether-alcohol collodion. This, it was found, could be altered by adding to the made-up solution a certain quantity of ethyl alcohol, the rate of evaporation of which is comparatively close to that of methyl alcohol. The more ethyl alcohol, up to about 50 per cent., that was added, the denser, the less porous and the clearer became the film. It is, therefore, easy to produce a film having controlled and regulated physical properties in these respects.

As to coating plates in a smooth and regular way, it is as simple and easy to do it with either the methyl alcohol collodion or the methyl alcohol plus a moderate proportion of ethyl alcohol collodion as it is difficult to do it with the ether alcohol collodion—a novice can do it at once. But to have a film which possesses known properties as regards density and porosity is not sufficient, for it may be highly desirable that during the processes of photographic development or intensification such physical properties should be varied or made the most of—I have found this extremely necessary in the case of several processes worked out during the war—and with a collodion film of the nature described nothing is simpler. If you require the film to be temporarily more porous, all you have to do is to put it in a bath of water and spirits, the amount of spirits determining the degree of porosity you will obtain. The time of immersion is not of great importance, as it very soon swells to the amount it is going to swell. As spirits, i.e., ethyl alcohol, will not dissolve the film by itself, you may immerse it in spirits alone for obtaining a fairly considerable increase in porosity. If that does not suffice, methyl alcohol may be added to the spirits, up to 25 per cent., to produce increased swelling or porosity. But if you go very much beyond this, although you do not dissolve the collodion, you begin to disintegrate it, and with spirit baths containing 15 per cent. or 20 per cent. of methyl alcohol, the time of immersion does tend to become a factor.

I have recently patented the use of methyl alcohol for certain special photographic emulsions, to which I have not referred this evening, but it seems to me that with the necessary research it might easily be found very useful and adaptable for other purposes, one which suggests itself immediately being the wet-collodion processes, for example.

However, my main point this evening is to suggest that the whole subject of the physical properties of the colloid films, with which photographers have continuously to deal, the bringing of these properties into greater service, or new ways of utilising these properties, is a field of research which will well repay greater attention than has perhaps been devoted to it.

JULIUS RHEINBERG.

To MR. W. B. FERGUSON we must express our regrets that by a clerical error his name was not included in the list of those elected to the Council of the Royal Photographic Society. No one on the Council has rendered so long and valuable service to the R.P.S., and therefore we have the more reason for removing any misapprehension among well-wishers of the Royal that he did not secure election.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Some Notes on the Use of Process Plates.

At first sight, and to the uninitiated studio worker, process plates appear to be the easiest of all brands to work—the slowness of the emulsion, the great latitude, the simple developer commonly employed, and the not having to bother about the rendering of delicate shadows and fine gradations—are all factors which so successfully "camouflage" the process plate as to make it appear to be the easiest thing in the world of photography to use. Habitual and successful users of the "black-and-white" (process) plate, however, know very well that, in spite of the apparent simplicity of the plate and operations connected with it, it is at first a little difficult to understand, having peculiar characteristics of its own; when, however, its idiosyncrasies have been mastered, it will be found to be an ideal plate for many purposes other than that it is intended for, which, as most operators know, is the copying of letterpress, pen-and-ink line drawings, and other purely black-and-white work.

We learn a lot from our failures, are told when we fail to try and try again, and few workers, I feel sure, have had in their early experiences with process plates, more disappointing failures than I met with, and it was not until I adopted a certain plan—one in which the factorial system of development is most prominent—that I now feel sure of getting a good result from every exposure I make. Indeed, for a long time when doing black-and-white work I chose to use ordinary slow plates and the hydroquinone-formaldehyde developer, but good as the latter plan undoubtedly is, it is both slow and unsatisfactory in comparison with a proper process plate properly exposed and developed.

Most, if not all, plate makers issue a process plate, and there is very little difference between them, all giving equally good results when properly exposed, and—what is most important—developed with the developer advocated by the makers. The average speed is H and D 25, though the plate made by the Barnet firm is as high as H and D 75. It is always said that the slower the plate the better it is for copying black-and-white originals, but this saying does not hold good to-day, because the extra speed of the Barnet plate is no detriment to its good qualities, but rather the reverse, as by its speed it becomes a very useful plate for use on ordinary subjects, *e.g.*, dull and flat interiors, architecture, and for copying ordinary photographs, when increased contrasts are wanted.

The developer is far more important than the plate, and since the introduction of process plates many formulæ have been advocated, *e.g.*, pyro-ammonia (Mawson), pyro-soda, metol-hydroquinone, glycin, and hydroquinone. To-day most authorities are in favour of hydroquinone, with, perhaps, glycin as an alternative, but in my experience there is nothing better than hydroquinone, post-war glycin not appearing to be quite so good as the pre-war product; but it may have improved since I used it. Process plate developing formulæ have changed considerably during recent years. Wellington, for example, advocated until recently a solution containing equal amounts of hydroquinone and potassium bromide (100 grs. of each to a pint of developer), as, I believe, the officials at Bolt Court do, but to-day the Wellington formula contains but 10 grs. of bromide and 80 grs. of hydroquinone to the pint. Multiplicity of process-plate developers, however, need not bother the photographer in the least, because a secret of success with any one of the makes of process plates is to use the formula advocated by the maker, and no other. The worker cannot—if he wishes to get really perfect results—ring changes with process-plate developers, as he may, and usually does, with others, and it is for this reason, I suppose, that no commercial ever-ready dry or liquid "universal" developer, no matter what its base may be, will give a result with a black-and-white plate equal to that obtainable with the formula specially recommended by the maker of the plate. Any one developer will, it is true, give an image upon a process plate, and such an image may satisfy some workers, but there is not the chance of getting a perfect black-and-white negative that one has when using the right developer. There is a great likeness between some of the formulæ, the Barnet and the Ilford differing but little, but small as this difference is, I would never use the Ilford formula for the Barnet plate, or the Barnet formula for the Ilford plate. A really serviceable universal developer may, however, come along in due course: it would be most welcome if it could be relied upon.

Most errors are probably made in the exposing of process plates, for in spite of the enormous latitude—mainly theoretical, however—accurate exposures are essential if the blackest of deposits and clearest of shadows are required. One may sometimes secure the necessary density and clearness on a wrongly exposed and developed plate by use of the mereury-ammonia intensifier or the ferricyanide-hypo reducer—using both in some cases—these after-baths being commonly used, but it is a saving of time, trouble, and expense to get a perfect negative by direct development.

Exposure meters serve very well for calculating exposures when the necessary additional calculations for eamera extension, etc., are made. If the increased distance (beyond the normal) between lens and plate is less than one-fifth the focus of the lens, it may be ignored, greater extensions, however, need attention, and the extra extensions and the necesary increases in exposures (the latter in parentheses) are as follows:—1¼ (1½); 1½ (2); 1¾ (5); 2 (4). Thus when using, say, a 6-in. focus lens at 9 in. from the plate, double the meter time is required. There are, I believe, other methods of calculating meter times for copying, but I know little or nothing of them, because I prefer to sacrifice a plate in the making of a test exposure. This testing I do by focussing a piece of newspaper and giving eaeh column of print, or marked sections to represent the same, a different exposure, using a blackened card for covering or uncovering the columns as required during exposure. If, I think, say, 30 secs. is a correct exposure, I arrange that exposure for the centre portion, giving sections on one side of it more, and portions on the other side less, exposure. I prefer this system to the meter, as one is enabled to see more clearly the degrees of density given, and can repeat the desired result with a big degree of certainty. Even when a meter is used it is no uncommon thing to have to repeat an exposure owing to something having gone a little wrong and the negative not being exactly of the type required.

Development is easy enough if the exposure is right, but most difficult if it is wrong. Uninitiated users of process plates are usually of opinion that by under-exposing and forcing development the necessary density can be obtained, but this is not the case, as only by giving sufficient exposure can one get the much-desired opacity of developed image. The great problem users of process-plates have to solve is that of getting a perfectly opaque deposit without blocking up the finer lines and veiling the whites. The factorial system of development may have its weak points when applied to the development of negatives of ordinary subjects, but for process plates it is the thing, and, using a factor of 6, one cannot go far wrong when using the hydroquinone developer. A shorter factor number (assuming, of course, the exposure to be fairly accurate) will not give the required density, while a higher one will result in the lines being blocked up. Thus, if the image appears in, say, 30 secs., developmentwill be complete in 3 minutes, and it is next to useless to develop for a longer or shorter period (with 30 secs. as the time of appearance), unless, of course, it is intended to use a reducer or intensifier, or both, as many workers are in the habit of doing. The usual factor for normal hydroquinone developers, when used for ordinary plates, is 5, but 6 is better for process plates, and even 7 or 8 may be used in some instances, *e.g.*, when originals are flat, if no danger of elogging the finer lines or veiling the shadows threatens. For glycin, a factor of 10 is, I find, suitable, but modern glycin in my hands tends to give a brownish-black image of insuffieient opacity.

Little need be said about fixing baths for process plates, as any kind of hypo fixer appears to serve equally well. I generally use the hypo-alum-acetic acid fixer, as I keep it made up for use with gaslight papers, and this particular bath is specially recommended for the Barnet process plates. In any case, an acid-fixer is to be preferred.

Brief mention has been made of the use of process plates for work other than the copying of black-and-white originals, and more attention might be paid to their uses in what may be termed ordinary photography. Mr. Harold Baker twenty-three years ago, when process plates were usually of a H and D 10 to 15 speed, called attention to their uses in other directions, and now that all

process plates are quicker—particularly the Barnet make—there is all the more reason why they should, in certain instances, be used for ordinary work when the increased exposures called for can be given without any inconvenience.

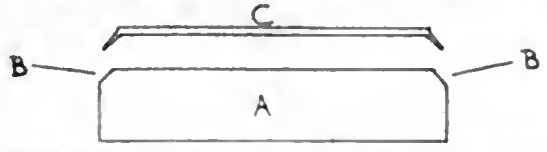
For interiors, when there is a nasty flattening haze in the air, and for architectural exteriors in smoky towns, process plates will give unusually bright results because of their "blindness" to haze and contrast-giving properties. For shop-fronts in busy streets, when there is a lot of traffic past the shops, and for interiors when people are walking about during the exposure, they are ideal because of their slowness, and operators would do well to take advantage of this method of overcoming the drawbacks of traffic, haze, and smoke, as, given the necessary long exposure, process plates will render half-tones quite as well as other plates, though, of course, the steps from black to white are steeper, a peculiarity—exactly like that of gaslight paper—operators can make very good use of.—L. TENNANT WOODS.

Photo-Mechanical Notes.

Mounting of Half-Tone Blocks.

A recent patent specification, No. 158,628, of Harold William Hood and Hood & Co., Ltd., Sandbride Works, Middlesbrough, describes an improved method of mounting half-tone blocks. It consists in providing a bevel or rebate on the wood mount for the purpose of allowing the bevels or lugs of the plates to be depressed below the printing surface to a greater depth. The copper or other metal bevel may be bent downwards out of the way of the inking rollers, and by so doing they may, if expedient, be made to miss being inked altogether by the rollers, and thus not print an unsightly mark or smudge, as frequently happens with inferior papers or loose cylinder-packing. Even if it is not found convenient for the rollers entirely to miss the bevelled edge of the half-tone thus depressed, it will be found in practice that that depression is so great that under no ordinary or even careless condition will it impress either the bevel or the nail head upon the paper round the edge of the picture formed by the half-tone block itself.

Another advantage of this mode of mounting a half-tone block is that of reducing the width of space required for the "bevel" -



in itself a marked advantage so that type matter may be brought so much the nearer to the illustration proper.

A further advantage of the method of mounting blocks is that the nails have a considerably reduced tendency to rise, owing to the fact that their position is far from the vertical and therefore the upward tendency much reduced; this in itself minimises the danger of rising nail heads.

In the drawing A represents a section of an ordinary mount for half-tone work, and BB represent the bevels, while C represents a half-tone plate with bevels arranged to fit the sloping bevels prepared for it on the wood or other substance on the mount.

The usual mounting nails could be used, or, if preferred, very small screws; indeed, the latter are preferred, because owing to the greatly increased security of the plate to its respective mount the difficulty of safely removing a plate mounted by the method is a serious one, which in itself goes to show the increased tenacity of hold that the plate has to the mount, and the reduced likelihood of the danger of the plate coming away during printing, as frequently happens, especially on old blocks.

The following patents have been applied for :—

COLOUR REPRODUCTION.—No. 6,908. Preparation of originals for photographic or photo-mechanical reproduction in colour. A. E. Bawtree.

INTAGLIO PRINTING.—No. 7,047. Process of printing from intaglio plates. Waterlow and Sons, Ltd.

PRINTING-PLATES.—No. 6,697. Production of gelatine printing-plates. H. Renck.

PRINTING PROCESSES.—No. 3,974. Photo-mechanical, etc., printing processes. Dye Impression Photos, Ltd., and W. H. Edridge.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, February 28 to March 5 :—

COLOUR PHOTOGRAPHY.—No. 6,859. Colour photography. F. W. Donisthorpe.

X RAY PHOTOGRAPHY.—Nos. 6,901 and 6,902. X-Ray photography. N. E. Luboshey.

CINEMATOGRAPHY.—No. 6,936. Cinematograph projection apparatus. A. R. Buttery.

CINEMATOGRAPHY.—No. 6,685. Cinematographic apparatus. G. S. James.

CINEMATOGRAPHY.—No. 7,066. Cinematographic apparatus. O. Messter.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

ONE LENS COLOUR CAMERAS.—No. 141,368 (January 8, 1919). The invention has for its subject an apparatus whereby separate films or plates, having the necessary colour screens placed in front of them, are exposed to rays of light emanating from a single objective.

Two mirrors are provided for each of the films or plates to which the rays of light are to be reflected so that the films may

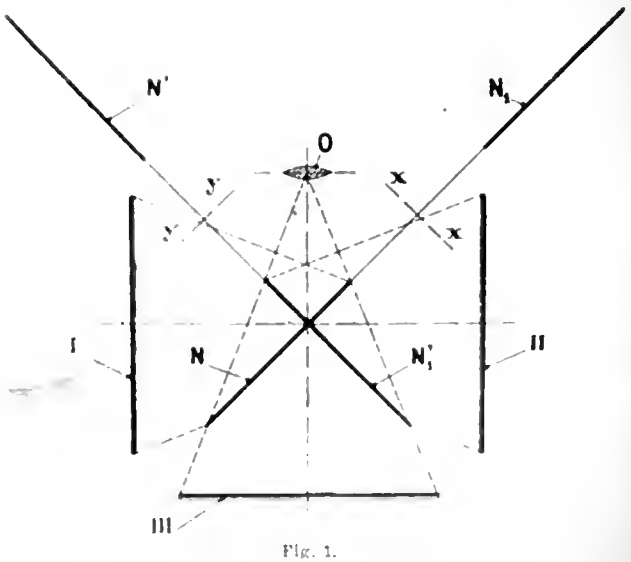


Fig. 1.

be exposed at a higher speed. These mirrors are driven by a common shaft by means of bevel gearing, all the driving mechanism being provided above the level of the objective.

The system comprises two pairs of mirrors N, N_1, and N' and N_1', turning respectively on the axes $x—x$ and $y—y$. The mirrors N, N_1 direct the image from the objective to the plate I., whilst the mirrors N', N_1' direct this image to the plate II. The plate III. receives the rays of light direct from the objective.

Each pair of mirrors N, N_1 (or N^1, N_1^1) is mounted on a hub A, carried in brackets B secured to a plate F. On the axes x—x, y—y are keyed bevel pinions C, D, which gear with a bevel wheel E. This bevel wheel E is keyed to a shaft G mounted in a bearing H provided on the plate F and in a bearing J provided in the top of the casing of the apparatus. On the shaft G is also keyed a toothed pinion K which may be driven by a suitable

Fig. 2.

clockwork or other motor. The plate F is adapted to be adjusted in position on the front wall of the casing so as to bring the mirrors into proper position relatively to the films or plates.

The two pairs of mirrors are mounted in such a manner that the system may turn continuously without collision between the mirrors N, N_1, N^1, N_1^1.

With the system in question it is necessary for the object to remain stationary on the plate during the exposure of the sensitised plate. This result can only be obtained if the mirror moves in a plane perpendicular to the plane formed by the axis of the objective and by its reflected image. The mirrors are inclined to

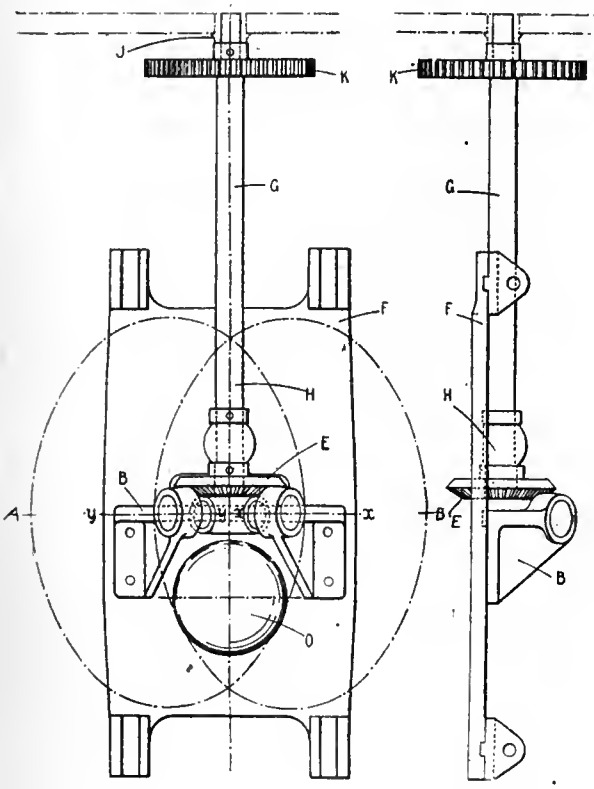

Fig. 3.

Fig. 4.

the axis of the objective at a suitable angle so as to reflect upon the sensitised surface an image, which is not distorted, during its movement.

With this method of construction any number of sensitised plates (2, 3, 4, 5 or more), each corresponding to a colour of the solar spectrum, may be printed upon. The selecting screens are placed immediately in front of the negatives.

This method of construction presents advantages for certain purposes; it permits of rapid displacement without any jerks and it is particularly suitable for colour cinematography.

For this latter purpose it would suffice to substitute for the three stationary plates I., II., III. three films unrolling in the same direction, the movement of the films being effected intermittently in the well-known manner.

The apparatus for taking photographs in colours (by means of rotary mirrors) lends itself to the stationary projection of images in colour, the mirrors being subjected to a rapid rotary movement during the projection. A similar arrangement may be used for

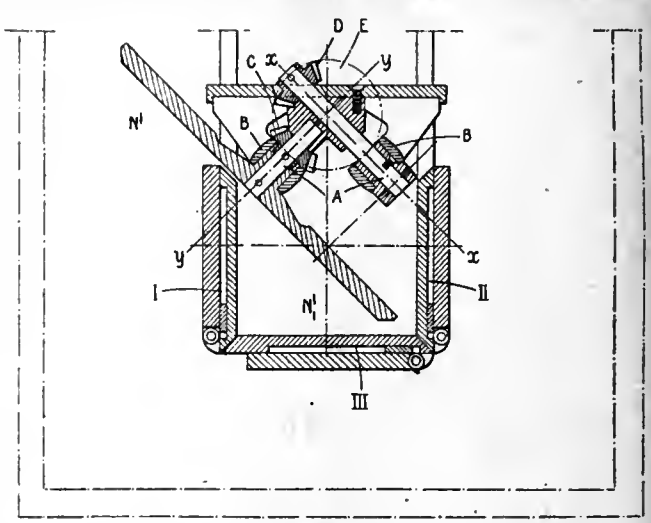

Fig. 5.

the projection of animated images in colours.—Jacquea Dourlen and Marcel Chretien, 64, Rue des Vignes, Paris.

The following complete specifications are open to public inspection before acceptance :—

STEREOSCOPY.—No. 159,192. Stereoscopic methods and apparatus. Optische Anstalt C. P. Goerz Akt.-Ges.

Trade Names and Marks.

FRIDAY, MARCH 25.

Bedford Camera Club. "After-treatment of Negatives."

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, March 15, the President, Dr. G. H. Rodman, in the chair.

The President announced that it had been decided by the Council not to permit smoking at the Society's meetings.

Mr. Arthur S. Newman delivered a lecture on the design and construction of reflex cameras, illustrated by blackboard drawings. He first sketched briefly the historical development of the reflex camera, which he attributed in its first practical form to R. J. Edwards. In the Vanneck camera the mirror acted as the shutter, and incidentally gave a four-fold exposure to the sky. The mirror did not form a light-tight seal with the focussing screen, which therefore was of yellow ground glass. A camera designed by Major Lysaght had a mirror which had a downward sliding movement. Mr. Newman referred to his own inventions of a jointed mirror, guided by slots, as means of avoiding fouling of the lens, and of the design of a camera to work with a shutter on the lens, and embodying an opaque flap, which followed the mirror, and released the shutter after the mirror had closed it. He referred to the making of a folding reflex camera as mechanically a most difficult problem if permanent precision of action and full range of movements were required.

In the design of a reflex camera the chief optical requirement was that the mirror surface when in the down position should bisect the angle between plate and focussing screen. It was not necessary that the angle should be 90 deg. A greater angle had been used giving an inclined position of the focussing screen, but surface defects in the mirror then became much more serious in their effect. The mirror should subtend the full cone of rays from the lens. Mechanically a chief problem was to balance the jerk of the mirror, the effect of which was to angle the lens axis, and therefore was much more destructive of definition than a shake which moved the axis parallel to itself. A constructor therefore sought to move the mirror slowly at first, then very quickly, and finally to bring it slowly to rest. Mr. Newman described various types of link movement effecting this acceleration and deceleration.

A brief discussion followed, in which Mr. J. C. Warburg and Mr. Walter Thomas took part, the latter referring to the many years an N. and G. camera had been in his continuous use without need of adjustment.

Dr. Adolph Abrahams delivered a lecture on the use of the reflex camera in reference to high speed photography. He explained that in photographing rapidly moving objects it was necessary to anticipate the moment of release of the shutter by a certain period of time in order to compensate for the human inertia. With a non-reflex camera the period might be 1-10th of a second; with a reflex, say, 4th of a second longer. It was necessary to know the camera in this respect; he had used a Videx for many years. He referred to the advantage of a swing front on a reflex and of long-focus lenses, in particular the Telecentric. Much of what Dr. Abrahams said was special pleading, and at times plausibility got the better of consistency.

At a somewhat late hour, reflex cameras were shown and briefly described by representatives of Messrs. Houghtons, Butcher and Sons, Kodak, Ltd., Ross, Ltd., and Adams and Co. Mr. R. Fonkes Wilks, of the last named firm, dwelt upon some of the points raised by Mr. Newman, and referred to the late Mr. A. L. Adams as having been the first to issue a commercial focal-plane reflex. He showed the box and folding patterns of Adams' reflex.

A late hour votes of thanks to lecturers and demonstrators brought the proceedings to a close.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held at 116, Hanover Street, Edinburgh, on Monday, March 7. Present:—Messrs. Campbell Harper, Ayton, George Beaman, Norman Thomson, Melrose, Fergusson, Laing, Yerbury, Moffat, John Thomson, F. D. Young, and Swan Watson.

Mr. J. Campbell Harper was called to the chair in the absence of the President, Mr. F. D. Young, who afterwards presided.

The meeting considered minimum prices for making negative and supplying proof for commercial photography, there being an unanimous feeling that some of the prices of prints, which had previously been approved of, were too high. Mr. Moffat suggested that the price should be fixed by taking the operator's time, *plus* the cost of material and a percentage over the whole transaction, but this proposal appeared to some of the members to be somewhat complicated, and necessitate additional book-keeping. After considerable discussion, the meeting unanimously recommended the following prices to be charged as a minimum for commercial photography meantime, and it was further resolved to remit the matter of fixing prices on a costing basis to a committee for further consideration and report. The following members were appointed to the committee:—Mr. Moffat, Mr. Yerbury, Mr. Norman Thomson, Mr. Ayton, and Mr. Campbell Harper. Mr. Moffat being appointed convener:—

For making negative and supplying one print	Duplicate Copies, Unmounted and Rough Trimmed. Each.	Mounted Each.	Large Mounted. Each.
	s. d.	s. d.	s. d.
15 × 12, £1 11s 0d	5 0	6 3	7 6
12 × 10, £1 1-	4 0	5 0	6 0
10 × 8, £1 1s	3 0	4 0	5 0
8½ × 6½, 12- 6d.	2 0	2 6	3 0
6½ × 4¼, 7s 6d	1 0	1 6	2 0

The meeting thereafter discussed the minimum prices for groups (black and white), which had been approved by the Society some time ago. The members felt that the Society's previous recom-

mendations were too vague and lacked detail. The President stated that it was distinctly understood and agreed to by the members when these prices were fixed that they did not include the price of printing nor mounts, and that the prices to be charged for a series of school classes or groups of workmen should be slumped. It was agreed, after the above explanations, not to make any alteration in the price meantime, but to continue the discussion at the next meeting of the Society.

It was agreed to hold an informal meeting of the Society at the Victory Café on Monday, March 21, at 8 p.m. A vote of thanks to the chairman terminated the proceedings.

SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.

At a recent meeting of the Society, Master Ivor Nixon, the sixteen-year-old photo-chemical student who last year surprised the members by giving a learned talk on the chemistry of printing processes in general, devoted an evening to Kallitype, giving his experiences with all the published formulæ, demonstrating where possible, and showing results—possibly the finest Kallitypes ever seen—obtained by the many systems of working. Master Nixon appears to have quite mastered the process, and although he was not able to publish anything really new concerning the preparation of the paper and development, his remarks were eagerly followed by many of the older hands, who had failed to get the results expected. The demonstrator had experienced considerable difficulty in getting a suitable paper, and had come to the conclusion that Whatman's "A.l.m." water-colour paper (series N) was the best, though expensive. The only chemical that had given trouble was the ferric oxalate, the commercial samples being quite unsuitable. However, he made the ferric oxalate at home, and found it to be the thing required to produce really perfect prints. The method he used is as follows:—Take a 20-oz. bottle, pour into it 4 ozs. of water, and mark the height of the water by means of a piece of paper stuck on the bottle. Pour out the water, and place in the bottle 400 minims of .880 ammonia and 8 ozs. 160 minims of water, then pour into the bottle a solution of 2 ozs. 80 grs. of iron ammonia alum in 8 ozs. of water. Allow the precipitate to settle, and wash it about ten times by decantation; allow the precipitate to settle well below the 4-oz. mark on the bottle, and syphon off the water above it. Next add to the mixture 420 grs. of oxalic acid, and allow to digest for about thirty minutes, by which time all the precipitate should have dissolved, and a clear, greenish solution should be the result. If necessary, filter the solution, make up to 5 ozs., and label "Ferric oxalate. Stock solution." If the proper ferric oxalate can be bought, the stock solution should be made by dissolving 75 grs. of it with 1 or 2 grs. of oxalic acid in each ounce of water. The solution should be kept in the dark to prevent decomposition, and it should give no blue colouration with a solution of potassium ferricyanide. The sensitising solution is made by dissolving 30 grs. of silver nitrate in each ounce of the stock ferric oxalate solution, and filtering; the sensitising solution does not keep good for more than two or three hours. The paper to be sensitised is pinned to a board, and the solution applied by means of a sponge or cotton wool, using strokes from left to right, and working from the top of the sheet, the board with the paper being placed at an angle of about 45 degrees. The paper, after coating, is allowed to stand for about ten minutes, and then dried very gently by heat; the paper is then ready for exposing. The sensitive paper should be stored in a chloride tin, like platinotype paper, although the paper will keep good for about a month without any special precautions. The paper at this stage is very much like platinotype paper, and is exposed in the same way, the printed image appearing faintly upon a yellow ground, and afterwards developed out. As is fairly well known, a large number of developers are advocated, each giving a different tone. Some developers need more care than others, and all were shown by the young demonstrator, who described their good and weak points. His favourite developer, and the one he considered the most reliable, was: Sodium acetate, 1 oz.; tartaric acid, 12 grs.; potass bichromate (10 per cent. sol.), 10 to 100 minims; water to 8 ozs. The potass bichromate acts as potass bromide in negative development, the more used, the slower the development and the greater the contrast; the black tones obtained were most pleasing. In the opinion of his hearers, however, the purple-black tones obtained with the borax developer were the most effective: Borax, 1 oz.; Rochelle salts, ½ oz.; ammonium acetate, 40 grs.; potass bichromate (10 per cent. sol.), 50 to 100 minims; water, 12 ozs. One set of prints produced with an oxalate developer ranged from black to a rich sepia, the demonstrator describing this as the most "sporty" developer because of the worker never being really sure what the final colour of the print would be, much appearing to depend upon the quality of the negative. The actual formula used was: Potass oxalate, ¼ oz.; potass bichromate (10 per cent. sol.), 5 minims; water, 2 ozs. The old hands present strongly advised the young enthusiast to abandon all developers in favour of the rather erratic oxalate solution, and devote his energies to the finding out the reason of the various tones obtainable with the one solution, and to devise a method of securing at will any tone from black to warm sepia with the simple solution. A detailed account of the sodium citrate and the Rochelle salts clearing baths and the hypo fixing bath concluded a very instructive lecture, the youngster being complimented on his photo-chemical knowledge and the excellence of his results. Until quite recently Master Nixon made all his own dry plates, and a lecture on the subject was promised for this season, but owing to the gelatinous condition of his parents' furniture and domestic utensils, his plate-making operations have been suspended by order.

Commercial & Legal Intelligence.

LEGAL NOTICES.—At a recent extraordinary general meeting of the members of Boyde's Studios, Ltd., held at 108, Strand, W.C.2, a resolution was passed to the effect that the company be wound up voluntarily, and that Mr. Richard William Simmons, corporate accountant, of 27-28, King William Street, E.C., be appointed liquidator.

NEW COMPANIES.

FRANK HUGHES, LTD.—This private company was registered on March 4 with a capital of £300 in 5s. shares. Objects: To carry on the business of printers, publishers, photographers, etc. The first directors are: F. W. Edmondson, 8, Clarence House, High Holborn, W.C., financier, and Mrs. M. P. Edmondson, 8, Clarence House, High Holborn, W.C. Registered office: 7, Southampton Row, High Holborn, W.C.

News and Notes.

REDUCTION OF PLATE PRICES.—As from March 14 last makers of dry-plates, which have been sold since about a year ago on the basis of 3s. 6d. per dozen quarter-plates, have reduced prices to the basis of 2s. 9d. per dozen quarter-plates. Half-plates are now 6s. per dozen, as against 7s. 4d.; whole-plates, 11s. 6d., as against 14s. On the basis of one dozen quarter-plates for 1s., which was the standard price up to the middle of 1913, the successive changes which have taken place in the price of plates are shown as follows:—

	s.	d.
Before June 16, 1913	1	0
June 16, 1913	1	3
March 13, 1915	1	6
February 29, 1916	1	10
March 1, 1917	2	3
February 5, 1918	2	9
August 1, 1918	3	8
March 11, 1919	3	0
February 16, 1920	3	6
March 14, 1921	2	9

It will thus be seen that the present reduction cancels the successive increase of 11d. on August 1, 1918, decrease of 8d. on March 11, 1919, and increase of 6d. on February 16, 1920, bringing the price again to the level to which it was raised by the advance of 6d. on February 5, 1918.

Mr. Thomas Illingworth, head of the Willesden firm of that name, has been appointed a Justice of the Peace for the County of Middlesex.

Kodak Postcards.—Messrs. Kodak, Ltd., announce that as from Monday last, March 14, the price of bromide, Kodura, Velox and Solio postcards has been reduced to 57s. per thousand: 55s. per thousand in lots of 5,000 and over. In the case of self-toning Solio the price has been reduced to 60s. per thousand.

The Australasian Photo-Review has once again—for the seventh time—appeared in a special issue in which all the contributions, literary and pictorial, are by Australians or photographers resident in Australia. The display of nationalism is an eminently creditable one, and in the respective fields of pictorialism and technics marks an enormous advance on the maiden effort. One contributor discourses on tone-masses in relation to Australian landscape, and another nobly engages with percentage solutions, armed for the conflict with the B.J. Almanac. We congratulate Mr. Walter Burke on having brought together a goodly company and also on having secured as sub-editor of his journal Miss Mary S. Lawson, who for five years was chief editorial assistant in the British Journal office, and lately had occasion to make her home in Australia.

BROMIDE STRIP TESTING APPARATUS, AND A SUGGESTED DARK-ROOM CLOCK

To the Editors

Gentlemen,—Having to make enlargements by daylight, and this being so variable, I have to make tests generally in geometrical progression. To hold a card against a strip of bromide paper on a vertical easel for 2, 4, 8, 16, 32 seconds, and sometimes a good deal more, is rather tiring, so I devised the little instrument which I illustrate. It consists of a board with six openings, with a shutter to each. The whole board is supported by two hinges, A, A provided with holes through which push pins can be passed so as to fix it in any position on the easel. A strip of bromide paper the length of the board is placed beneath; two joints an eighth of an inch long at each end of the board pin the strip to the easel when the board is pressed down. Before exposing all the six flaps are pulled out and hang down, then I begin the exposure while a metronome ticks seconds on a shelf near by. At two seconds the first flap is closed, at four the second, at eight the third, and so on till the last has sixty-four seconds. Then the cap is put on the lens and the strip developed.

There are several advantages in this, to my mind. First, the portion of the negative for testing is selected in advance, and the small apparatus placed there. Secondly, there is no fatigue in making the test; and thirdly, as far as I am concerned, I find it easier to judge of the density of strips of equal area separated by a small white band. I have often found in the strips shaded by a moving card that it was hard to tell, even with exposures in geometrical progression, let alone the arithmetical, where one exposure ended and the next began. In this case each part is perfectly defined, and there is no hesitation in knowing which has had so many seconds.

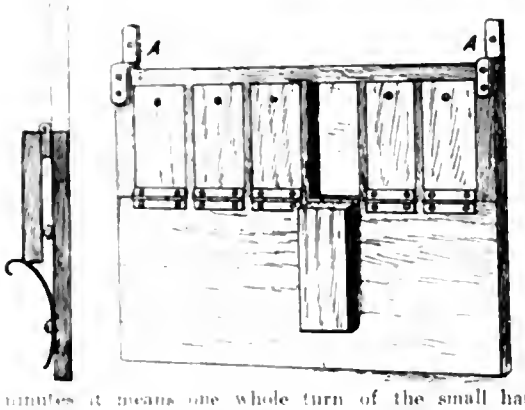
I admit that as it is the apparatus is a bit clumsy, but it was made by a local joiner. If it were made by cabinet makers accustomed to camera work it could be a quarter of the size, thickness, and the weight could be reduced in proportion. An improvement might be to have the flaps held open by a catch, with a spring to close when the catch is released, as in the short exposures it requires some dexterity to close the first just in two seconds and the same for the second; with a catch it would be easier to release it just as the metronome gives its second tick. The whole thing need not be more than 5 in. long. The catch could be of the form shown in the sectional drawing.

Of course, this only applies to easels without glass to hold the sensitive surface. By the way, I should like to say I use a cork bath mat, which has a perfectly flat surface, and in which pins can be pushed to further orders, and which is very light to handle, even though an inch thick.

I also beg to submit a dark-room clock which I got a local watchmaker to make for me from an ordinary 4-inch timepiece. By taking out a certain arbor and putting in a weak spring the whole clock has been made to run sixty times faster. The minute hand runs round in sixty seconds, and the hour hand in 12 minutes.

I had a Watkins' clock at one time, but the great disadvantage of it was the decimal division 10 minutes and 100 seconds. You never knew where the seconds hand would be at the end of the minute. If you started at zero the first minute would end at 60, the second at 20, the third at 80, the fourth at 40, and it was only at the fifth minute that it was at the top of the dial again. As for the clocks that give hours, and sixty minutes (on a four-inch dial often with a bevelled front glass) they are no use in a dark-room, even with plenty of safe-light, as the divisions are too small, and when development runs into hours an ordinary watch which everybody possesses will give all the information needed.

Now, what objection can there be to a clock of twelve minutes? None whatever to people accustomed to shillings and pence, or feet and inches. Everybody knows that fifteen pence is one and three, and the same applies to the clock. If you have to develop for



fifteen minutes it means one whole turn of the small hand and three minutes, with the advantage that those big divisions of the minute can be seen in any light, and the whole minute always ends at the same place.

Unfortunately having had to put in a weak spring on account of the reduced internal resistance my clock runs down in half an hour.

I should like to see on the market a similar clock which would go for a day, and if it could be made to tick seconds audibly so much the better for those who have to work in complete darkness, or for those who, using the factorial system, watch for the first appearance when they obviously cannot have their eye glued to a clock at the same time. And if further, the hands would fly back to zero on the pressure of a lever—but that is too much to ask.

A. Thomas.

THE PROBLEM OF HALATION.

To the Editors.

Gentlemen,—This problem, like the poor, seems always with us, and I am sure we should all be grateful to Mr. Godfrey Wilson if he can find out and reveal to us the developer which will cure the complaint. But I, for one, am rather sceptical as to any such simple remedy as a special developer curing a complaint which is so complicated. I wish it could be so easily cured. Only to-day I had a bad case. I really don't see how any developer could have effected a cure, and I am afraid the amateur's idea about over-exposure being the cause, and suggesting a remedy, is no good, for he seems to think a mere reduction of the exposure would prevent the trouble. In this particular case a war memorial had to be photographed; it is oak panelling, with a carved and perforated cresting along the top. About a foot or more above the cresting is

the sill of a window, and a foot of the stained glass appeared at the top, reduced to perhaps a quarter of an inch on the negative. The day was dull and the church was dark, and a small stop was necessary to get all the names on the oak panelling sharp enough to read; some incandescent gaslights were turned up to buck up the daylight, and an exposure of one and a half hours was given. On development, the film proved to be hopelessly under-exposed, but the halation had crept a long way down the plate. The only way I can see of obtaining a successful result is to cover the bottom of the window, on the outside, for nine-tenths of the exposure, give a still longer exposure, and finally to complete the exposure and to brighten it all up, give a flare with a good flash light. But I cannot see that over-exposure is the cause of the halation. It is true that the small piece of window was over-exposed, but the rest of the plate was under-exposed, and I believe if the whole of the plate had been fully exposed, there would have been less halation apparent.

We are apt to forget that a certain amount of halation will often appear in the actual scene, especially in the dusty atmosphere of towns. But if there is a developer that will cure or stop halation, will some good, kind soul let us know if it. One method has been suggested, and I have used it, sometimes with success, sometimes otherwise. It is to start development with a restrained developer, say pyro-ammonia, with a minimum of ammonia. When the windows, which would usually be over-exposed, are fairly well developed, the plate is well washed and local development carried out with metol. Some have suggested even painting the windows with a solution of bromide before proceeding with the metol developer. But the difficulty is that the halation causes most mischief when it spreads from the windows over the dark places that usually surround them.

I am afraid there is no *one* cure for the trouble. It can only be overcome by taking a number of precautions, and one of them, I believe, is backing. But the thin red coating often sent out is not much good; the solid black backing that one gets on panchromatic plates will do much to minimise halation. Films are supposed to give less halation than plates, but my bad result of to-day was on a film.

Some months ago, in the columns of the "B.J.," a method was suggested to stop halation. It was to hang a piece of opaque paper, cut to the shape of the window, in front of the lens by a wire from the top of the camera. Some twenty years or more ago this method was sold as a great secret. I tried it then, but found it so extremely difficult to fit the mask to cover the window accurately that I gave it up. Of course, when the exposure of the rest of the plate was complete, the mask was removed for a few seconds before the lens was capped.

Even with special anti-halation plates, in which there was a stained film between the glass and the sensitive film, halation sometimes occurred. I agree with Mr. Wilson, we have a lot to learn about it.

BIFOCAL.

APPROPRIATE FRAMING.

To the Editors.

Gentlemen,—In your article on the above subject you conclude with the remark, "Home frame-making on a small scale does not pay." I beg to be allowed to differ from you on this point. There appears to be no reason that even a single frame should not show a profit, apart from the convenience in ensuring the certainty of delivery in time. This is providing, of course, that one is not cramped for space and that there is sufficient room for the materials and tools to be always ready—a place for everything and everything in its place. I recently took an order for an enlargement, framed complete in stained oak, with name plate, for a presentation. Following my usual custom, I ordered the frame from a firm that had always served me well. The frame duly arrived by rail; the name plate I had already obtained. The portrait was in my finisher's hands when the club secretary called on the morning of the great event. In the circumstances I felt in a position to promise "absolutely without fail" for that evening.

When proceeding to fit up, lo and behold the frame proved to be the wrong size and out of proportion. The heads of the local high-class firms to whom I told my woes gazed at me with lack-lustre eyes, and the best I could get was a half-promise for the following day. Like many seaside visitors looking for "digs," I was at last compelled to resort to the back streets, where I remembered seeing a notice, "Frames made while you wait." The "boss" turned out to be a thoroughly practical man, and kindly invited me to witness the performance.

A pot of glue was simmering on the gas stove. Going to the moulding rack, he drew out a length of figured oak. Laying this on his mitre block he proceeded to cut the four sides to the required size. Placing these, one mitre at a time, in position, he planed them accurately with the aid of a "shooting board." The vice was then visited, a long side placed in the jaws and a short one nailed to it, the other sides being treated in a similar manner. A box of various-coloured putties was to hand, and the holes left by the punch were soon stopped. After a slight rub with glass-paper the frame received a liberal application, using a hog-hair brush, from a bottle of spirit stain.

Glass of different sizes were in the rack, which he mentioned contained only the best quality, so extracting the diamond from his waistcoat pocket it was only a matter of a few seconds to trim the glass into the frame.

With a stout strawboard back the picture was soon complete, and mutual satisfaction obtained by my handing over a pound (£1) note, the whole transaction being completed under the hour.

I noticed that his workshop looked much the same as when I entered. After my vain attempts the room has always presented an appearance similar to the scene of Huns' hurried departure.

It would appear that this tidiness is essential to success from a profit-making standpoint, and coupled with practice it should only be a case of "the more the merrier." In this particular instance it was far better than to hear a member of the committee remark:—"That's Smithson—the man who 'let us down' with the presentation."

H. G. S.

HEALTH—AND THE PRINTING PROCESS.

To the Editors.

Gentlemen,—There is one point that Mr. Willis does not mention in his refreshing article on "Distinction—and the Printing Process," and that is that Platinotype or carbon entails no dark-room work, and is therefore far less trying for the eyesight and healthier for the worker than bromide. When so many semi-invalided ex-soldiers seem to be taking up photography this is an important factor in the choice of a printing medium.

For twenty years I have used either platinum or carbon, and when necessity made me start professionally a year ago, I decided to stick to these two processes, not only for the excellent reasons Mr. Willis gives, but also from the health and eyesight point of view. In spite of all prophesies that this decision would be impossible to carry out, I have never executed any order in any narcotic process. Platinum for a thin negative and carbon for a strong one have always met with nothing but appreciation. There seems room for a training school for printers; it is worth thinking about.—Yours faithfully,

JANET ALLAN.

Wallington, Surrey.

A SUGGESTED METHOD FOR COPYING FLAT OR WEAK NEGATIVES.

To the Editors.

Gentlemen,—I have read in your paper at odd times, articles on copying and on dealing with the making of negatives from weak copies. The best advice given seems to be that of using contrast-giving plates, viz., slow ordinary, or process. Now my opinion of the resulting negative, obtained by using process plates, is that, in general, sufficient contrast is obtained for the actual subject, but the defects in the background, due to uneven fading, discolouration, or texture of old paper, are so emphasised that the negative or print does not satisfy the critical photographer.

Here is a method of obtaining sufficient contrast, combined with softness, which I have not yet seen published.

Many years ago I had a weak faded print to copy. The first negative was too weak. I studied the negative and gave another exposure with altered exposure and development. The resulting negative was better, but still weak. The two negatives were put to wash while I considered the matter. Later on the negative was picked up from the washing water, examined, and, strange to say, found to be of an ample density or contrast. For a moment satisfaction only filled the mind, but the enquiring department of my

again soon asked "Why?" The solution was as follows:—The negatives in the washing water had slipped one over the other, and having been exposed without shifting the camera, they registered exactly, when placed one over the other, with the thickness of the glass between the two images.

Now, my procedure in cases of extreme flatness is to take a negative on an ordinary plate, criticise the exposure and development, and make another negative. Then take the best negative and retouch, place the other negative in register, and bind together as in lantern-slide making. Either negative or both, whole negative or part only, can be reduced, stained, etc. In your print you get the sharpness from the primary negative and diffused addition of density from the secondary.

I have often thought that a similar result, and, perhaps more under control, could be obtained by the dusting-on process, coating the glass side of the negative with the bichromate solution.

The next time you are up against an extremely weak print to copy, just try this method. A. CHARGOIS.

Cairns, Queensland.
January 18.

FACTORIAL DEVELOPMENT.

To the Editors.

Gentlemen,—The letter from Mr. Alfred Watkins on March 11 called attention to the influence of the printing process upon the Watkins factor to which the plate should be developed. He wrote that "The best amount of contrast (a steepness of gradation) for one printing process is *probably not* the best for another, and here, again, the experience of the old photographer may lead him to modify the factor." The italics are mine.

It is certain that the various types of printing paper (gaslight, bromide, carbon, platinum) require negatives which have been developed to very different times when it is desired to depict the same subject as a print of the same appearance upon each type of paper. The two extreme printing papers are vigorous gaslight paper and platinum. The former has an exposure range of 1-10 and the latter about 1-100. The exposure range of a printing paper is the relationship between the least exposure required to give the faintest grey upon the print, and that required to just give the deepest black. It is the business of the negative to utilise the exposure range of the paper during printing. Let us assume a subject whose range of light intensities is 20-1, an average open-air outdoor subject including bright sky. To produce a negative suitable for printing upon vigorous gaslight paper, the printing range of the negative must be about 1-10. A 20-1 subject is rendered as a 1-10 negative by development to a gamma of .77, $\left(\frac{\log 10}{\log 20}\right)$. From the same subject, however, a negative equally suitable for platinum paper must have a printing range of 1-100. To produce a 1-100 negative from a 20-1 subject requires development to a gamma of 1.54, $\left(\frac{\log 100}{\log 20}\right)$. The gamma .77 negative will, upon vigorous gaslight paper, give identically the same print of this particular subject as the gamma 1.54 negative will upon platinum, certain very minor differences excepted. With low Watkins factor developers (pyro, hydrokinone) gamma 1.54 is only reached in 2-3 times the length of time of development for gamma .77, equivalent to an increase in the Watkins factor of 2-3 times. With high Watkins factor developers (metol, rodinal), whose characteristic is a high development velocity in the early stages of development, rapidly falling off in the later stages, the factor suitable for a negative for vigorous gaslight paper may have to be multiplied by 4 or 5 in order to yield a negative from the same subject suitable for platinum.

The failure on the part of many photographers to recognise that every type of printing paper requires a negative specially made for it has led to many disparaging comparisons being made between one printing process and others. When bromide paper was first introduced, the general complaint was that it gave harsh results. Failing to recognise the comparatively short exposure range of bromide paper, photographers were attempting to print upon it with the long-range negatives which for years they had been making for P.O.P. carbon and platinum. To-day history is repeating itself. Vigorous gaslight paper stands condemned as a harsh contrasty paper. It is nothing of the kind. Accustomed at the present time to make negatives of a suitable range for printing upon bromide paper, photographers have yet to grasp the fact that these negatives are too long in range for vigorous gaslight paper. If a specially short-range negative be made for vigorous gaslight paper, the resultant print is indistinguishable from one made from an appropriate negative upon any other printing process, colour of deposit, and character of surface excepted. In his excellent article last week, called "Distinction—and the Printing Process," Mr. A. G. Willis, on page 137, line 21, column II., writes: "To many workers it would be a revelation to see a carbon alongside a bromide from the same negative." It is perfectly true that if the negative were suited for carbon, then it would give an unsatisfactory result on bromide paper, but it is equally true that if that negative had been suited to bromide paper, the result upon carbon would have been unsatisfactory also. It has for years been a popular fallacy that prints upon different papers made from the *same* negative may justifiably stand compared as an index of the "quality" of the printing process. A comparison so made is false.

When Mr. Watkins revises his manual again, I hope that he will be able to see his way to alter the words "probably not" into "certainly not."—Yours faithfully, B. T. J. GLOVER.

Sunnymere, Birkenhead Road, Meols, Cheshire.
March 13.

[We are glad to be able to say that we have in type for appearance shortly a paper by Dr. Glover dealing with the practical relationship between the subject, the negative and the type of printing paper used, and considering to what extent various methods of negative development enable the correct relationship to be fulfilled.—Eds. "B.J."]

LENSES v. CHIFFON FOR DIFFUSION.

To the Editors.

Gentlemen,—When I read in the "B.J.," of March 11, the discussion on chiffon, by the R.P.S. Pictorial Group, I had to go over it again to satisfy myself that they were not bluffing.

Why does Mr. Lawton eulogise chiffon in one sentence, and in the next scorn it with the withering remark: "It produces general fog"?

Surely general fog is a thing to be scorned like a pestilence, especially in portraiture, pictorial or otherwise. I hesitate before my next remark for fear of encroaching on their preserves, but would suggest they move with the times.

To my idea, chiffon was played out with the advent of modern lenses, whose powers of diffusion tolled the death knell to unnatural, undesirable, foggy softness. During my thirty years' experience in photography I have used all kinds of devices to obtain softness, and have come to the conclusion that there is no instrument or material equal to the Cooke portrait lens for giving a clean, sharp, or soft, foggless negative or enlargement.—Yours faithfully,
RALPH JONES.

St. Anne's-on-the-Sea.
March 14.

THE OLDER PRINTING PROCESSES.

To the Editors.

Gentlemen,—To an "old timer" it was indeed a pleasure to read Mr. Arthur G. Willis's article, "Distinction—and the Printing Process."

The necessity for extra-rapid completion of work having passed with the war, photographers generally might do much worse than turn their attention to the processes whose merits are there so ably set forth. As an assistant, I think the rage for bromide papers is largely responsible for the ousting of male labour from the ranks of photographic workers. To those unemployed it is very disheartening to see, week after week, a "lady" insisted upon, and so often for work which has generally been regarded as fit for men only. As a printer, I have no prejudice against bromide papers, but I maintain that it is impossible to obtain results thereon equal to those on carbon or collodio-chloride matt paper. And is Mr. Willis quite sure that good printers in those processes are "quite unobtainable"? I, for one, should be very glad of the opportunity to prove the contrary.—Yours truly,
"OLD PRINTER."

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

B. E.—If the Wray lens is of *f*/8 aperture and in good condition it has a value of about £2 10s.

H. N. W.—The address for which you ask is MM. Grieshaber Frères et Cie, 12, Rue du Quatre-Septembre, Paris.

G. B.—We are sorry that we have no particulars of the maker of the automatic camera. We gathered from the few particulars we received of it that it is not yet on the market.

E. H.—As the photographs of the football teams were made to order, all rights of reproduction are the property of the person or persons who gave the order. You are not entitled to any reproduction fee.

T. E. B.—We cannot find a formula in the "B.J." answering to your description, but bisulphite is a very common method of making up an acid bath, and a very suitable formula is as follows:—Hypo, 4 ozs.: soda bisulphite liquor, 1 oz. (fluid); water, 20 ozs.

P. M.—You do not require any licence or registration in order to sell post-cards or take portraits, but if you don't trade under your own name (this applies to any business), you require to register with the Registrar of Business Names, 39, Russell Square, London, W.C.1.

J. P.—In so short a studio the longest focal length you can do with for a full-length post-card portrait is 6 inches, that is allowing 3 ft. space behind the sitter and also 3 ft. behind the camera. Supposing you allow only 3 ft. for both these places, then you could use a 7½-inch at a pinch.

S. A.—A total candle power of 5,000 should be ample. Most users of electric light would prefer to divide up between 5 lamps each of 1,000 c.p. We are afraid we cannot suggest what the announcement of the opening of a studio should be. Surely you can best do that with your knowledge of local conditions.

F. P.—We don't think they can turn you out unless they can find other accommodation, but the Rent Restrictions Act is such a complicated measure that we don't profess to understand it, and suggest that you ask the question from one of the daily papers, *e.g.*, the "Daily Chronicle," which has a department specially for the purpose.

H. W.—About the most promising branch is process work, not necessarily half-tone and line block making only, but the other branches of photogravure, collotype, and photo-lithography. A youth could obtain thorough training at the L.C.C. School of Photo-Engraving, at Bolt Court, Fleet Street, London, E.C.4. Mr. A. J. Bull, the Principal of the School, would gladly give you every information by letter or at a personal interview.

R. H. W.—"Photography Made Easy" is a very good book, although it does not deal specially with tank development. Nevertheless, it is the best book a beginner in photography can have, and the chapter on development ought to be an effective guide to you in conjunction with the tables for time development issued by Messrs. Johnson, 23, Cross Street, London, E.C.2, for use with their "Azol" developer, and by Messrs. Burroughs Wellcome, Snow Hill Buildings, London, E.C.1, for use with their "Rytol." These tables can be had on application.

C. H. M.—(1) We do not know the wholesale makers of the anti-sulphuric paint. We find it is obtainable from any dealer in electrical requisites. If not obtainable in your town, you could certainly get it from the Economic Electric Co., Twickenham. (2) We recommend the "Howellite" inverted burner to be used in the ordinary position in the enlarging lantern—that is, without the mirror. Used in that way it gives an exceedingly good light, and though the angled mirror has been recommended for securing the tip of the mantle as the light-source, we do not think there is any advantage in it.

L. P.—The best type of lens for portraiture is a portrait lens of the so-called Petzval type. A suitable focal length for cabinet portraits is about 10 inches, providing you have plenty of space. But a 10-in is a big lens, and it is very doubtful that your camera, if it is one of the field kind, will carry it. We expect you will have to compromise in one direction or the other, either in the way of aperture or focal length. Better to sacrifice aperture than focal length within reason. Probably your camera would take quite well a 9-inch lens of *f*/6 aperture, which would be a very good choice, and can be made among a whole lot of lenses on the market of different prices.

A. W.—There is no useful purpose gained by stopping down further than *f*/16 for the sake of improving the definition of the lens or getting further depth of focus. We think you ought to be able to give a short enough exposure at this aperture on ultra-rapid plates to avoid want of definition from movement of the children, and if the plates are correctly exposed and developed to a thin crisp negative they would enlarge quite well. Of course, the shorter the focal length of your lens the larger relative aperture (speed) you can use for the same amount of depth of focus. There is no need to use such a long focus as 8 ins. for a negative, which we suppose is about 2 ins. × 2 ins. One of 5 ins. at the outside is long enough, and with this *f*/11 ought to give you ample depth.

W. A.—(1) Usually the F. number without a stop is somewhat smaller than when the largest stop is inserted. As a rule, there is a pair of rings within the lens-tube between which the Waterhouse stop is slid. If the aperture in each ring is larger than the aperture in the largest diaphragm, naturally the lens will then be working at a smaller F. number. However, no harm in seeing what kind of definition you get in the margins without the largest stop, but you must cover over the slit in the tube with an elastic band, otherwise there is danger of fog. (2) On no account must light leak in through the fitting of the lens-panel to the shutter. It would seem that you require to have a better fitting made, either a deeper rebate against which the lens-panel comes, or an arrangement by which the lens-panel slides in grooves, as on an ordinary camera. (3) A magnifier makes the image on the ground glass both brighter and larger, and is a great aid to focussing in both of these respects. The best form of magnifier is that sold as the Ramsden eye-piece, a good pattern of which you can get from Messrs. Sinclair and Co., Ltd., 54, Haymarket, London, S.W.1.

JOURNAL OF PHOTOGRAPHY.

No. 3177. Vol. LXVIII. FRIDAY, MARCH 25, 1921. Price Fourpence.

Contents.

SUMMARY.

A reminder that the last day for the receipt of exhibits for the forthcoming exhibition of professional and commercial photography, arranged by the Professional Photographers' Association, is April 7 next. (P. 165.)

In a contributed article, "Thermit" discusses the seasonal problem in the development and printing of amateurs' films, and finds a solution in the production of a superior grade of print (P. 167.)

Messrs. W. F. A. Ermen and Raymond E. Crowther, in a note on the variation of the Watkins factor of Monomet developer used with different quantities of soda carbonate, suggest the formula which they consider to be the best. (P. 168.)

Mr. E. P. Wightman and Dr. S. E. Sheppard, of the Eastman Research Laboratory, review recent work on the relation of the size of the grain to the properties of an emulsion. (P. 169.)

Mr. C. H. Bothamley has been elected president of the Photographic Convention, and Bristol chosen as the place of meeting in July next. (P. 165.)

A demonstration was given last week in London of the first result of the process of colour cinematography worked out by Professor Procoudine-Gorsky. (P. 173.)

In a contribution to "Photo-Mechanical Notes," Mr. E. L. Turner gives working formulæ for methods of producing reversed blocks (as regards light and shade) without making a positive for printing. (P. 173.)

Methods of masking for making several negatives on a single plate are also described in "Photo-Mechanical Notes." (P. 173.)

A correspondent, as the result of his experience of the "professional" developer recently recommended by Mr. P. M. Jones, recommends a revised formula. (P. 179.)

An extension box should serve a double purpose: if made reversible it allows of a short-focus lens being used in copying. (P. 166.)

Some of the considerations which require to be given to the use of a studio, the bearings of which expose it to sunlight, are dealt with in a leading article on page 166.

Mr. A. Lockett gives a simple rule for finding the diagonal of a plate. (P. 172.)

Failure in maintaining customers for special work may often be due to so low a scale of charges that the work cannot be satisfactorily done at a profit. (P. 166.)

A convenient plan for the comfortable and effective accommodation of the retoucher is described in a paragraph on page 166.

EX CATHEDRA.

Fair and Congress. On the eve of Easter we must not omit to remind our readers of the opening of the Photographic Fair at Westminster in three weeks' time and of the Congress of the Professional Photographers' Association which runs concurrently with the latter part of the period of the Fair. We understand that large measures will be taken in the daily Press for bringing the Fair prominently before the public. The exhibition of professional and commercial photography is to be on view on the opening day of the Fair, namely April 15, so that little time now remains for those who wish to try their fortunes in being represented in it. The entry form is obtainable from Mr. Marcus Adams, 43, Dover Street, London, W.1, and requires to be sent, together with the exhibit, so as to reach Mr. R. N. Speaight, at 157, New Bond Street, not later than Thursday, April 7. We endorse Mr. Lang Sims's appeal, which appears in the P.P.A. council report on another page, that those intending to take part in the Congress should send in their names (and subscriptions) to him without delay. It will then be possible to publish a list of names and their respective badge numbers in advance of the opening of the Congress—a little piece of organisation which in previous years has been shown to be of great value in making members known to each other, and which, therefore, deserves to be carried out as completely as possible.

* * *

The Convention. The forthcoming meeting of the Photographic Convention, which will be the thirty-third held by this association, is to take place at Bristol from July 4 to 9. At a council meeting of the Convention, which was held last week, Mr. C. H. Bothamley, F.I.C., was unanimously elected president and Mr. Walter Potter and Mr. F. J. Mortimer were re-elected hon. treasurer and hon. secretary, respectively. In electing Mr. Bothamley to the presidency, the Convention council is choosing one of the oldest and most enthusiastic "conventioners." We think Mr. Bothamley must have attended every meeting; at any rate at the second meeting, held in Glasgow in 1887, he read a paper on orthochromatic photography, and has frequently made notable contributions to the proceedings of the Convention over which in 1890 at Chester he presided. We understand that at Bristol his desire to make the Convention the occasion for the presentation of technical contributions to photography may bear fruit. He has our wishes that it will, for we have always been firmly convinced that the Convention cannot live by holiday making alone. Among other excursions which are planned in connection with the Bristol visit is one which, it is hoped, it will be possible to make, viz., to Fox Talbot's home in the village of Lacock, near Chippenham. That certainly ought to be done. Lacock is the Mecca of English photographers, and, moreover, the buildings of its quiet stone streets are

a delight to the eye. It was while living at Lacock Abbey that Fox Talbot began his photographic experiments. The window can there be seen which figured as the subject of a paper negative which he made in the year 1836 and which we believe is still in existence. His early photographs included numerous views of the picturesque abbey.

* * *

Fixing Prices. We are often asked by those opening new businesses to suggest a scale of charges. This cannot be done, for much must depend upon the nature of the locality; high prices are prohibitive in a poor neighbourhood, while low ones are viewed with distrust in a wealthy one. A safe plan is to adopt the highest scale of prices which are being obtained in the district and to make sure that the work offered is worth it. It is a bad policy to cut prices and send out inferior work, as this does not tend to keep customers after their first experience. Low prices mean an unwise economy in plates, the use of inferior mounts, and in many cases the issue of prints which should be destroyed. A conversation, which was repeated to us, points a moral. A young photographer, watching an old one doing a difficult copying job, remarked that with such an expenditure of time and plates no profit could be made. The old hand said, "What would you charge for this?" and received the answer, "About seven and sixpence." "Ah!" was the reply, "I get two guineas for it, so can afford to do it properly."

* * *

Light for Retouching. The usual retouching desk is often an inconvenient article in the work-room, blocking up a great part of the window and preventing the use of the bench for trimming, spotting and other work. We have recently seen an arrangement which obviates this difficulty and enables the retoucher to work in greater comfort. In a dark corner of the work-room a curtain is suspended so as to cut off all daylight, and in the little cubicle so formed, the retouching desk is placed close up to the wall. Behind the opening an incandescent electric lamp, screened with bluish glass or tissue, is fixed. The advantage of this is that the retoucher is not enclosed in a small hood and that the light is always uniform. It also does away with the necessity for moving the desk for any other work. When a special room can be devoted to retouching it is a good plan to dispense with hoods and to fit dark blinds to the windows so that the only light which enters comes through the negatives. In one establishment the remainder of a room so fitted is used for the storage of negatives, and this arrangement was found to be very satisfactory.

* * *

Camera Extensions. Although most modern studio cameras have an adequate length of bellows, there are many serviceable instruments which have too short an extension to allow of large heads being taken with the long-focus lenses which are now generally recommended. In order to overcome this defect it is a good plan to fit a reversible box front, by means of which a foot or more may be added to the working length. The fitment consists of an extra sliding front or lens panel carrying a box of the desired length, the front of this being made to receive the ordinary lens panels. It should be arranged so that the box may either project outside the fixed camera front or be put inside the bellows, so that in addition to facilitating the use of long-focus lenses, it also permits of those of short focus being used as well. This is very useful when making very small copies or portraits, when the bellows does not close up sufficiently to allow of a carte or quarter-plate lens being used. A slight difficulty may arise when a shutter is fixed inside the ordinary front, but if the rebate is cut away from one edge of the normal front and two or more buttons substituted, the front can be removed carrying the shutter with it.

SUNLIGHT IN THE STUDIO.

It is generally believed that it is impossible to produce good portrait negatives in a studio which is so situated that the direct rays of the sun fall upon the glass during any considerable portion of the day, and many photographers pass over otherwise eligible positions on this account While a northern aspect is highly desirable, it is by no means indispensable; by the exercise of a little ingenuity it is quite possible to work successfully in a studio which faces due west or even south. The main difficulty to be overcome, especially in large towns, where the atmosphere is always more or less foggy, is the flood of light between the lens and the sitter which entirely precludes the obtaining of clear shadows, and also tends to shine directly into the lens and still further flatten the lighting.

A lengthy experience in a studio which receives its light directly from the west has shown that the difficulty is more easily overcome than might be imagined. There are two methods of doing so, the older being by the use of screens or louvres inside or outside the glass, and the other that of employing diffusing media which prevent the direct rays from entering. The former method depends upon the use of frames arranged upon the principle of the domestic Venetian blind, which only permit light to enter in one direction, and when these can be conveniently used, is extremely efficient. These frames, which are of the full length of the side and top lights, are covered with opaque material and hinged to the sash bars, being controlled by cords or rods so that the angle may be altered to suit the varying conditions of light. When viewed from the sitter's position the edges of the frames only are visible, while the operator cannot see the glass at all. In this way the working light is quite unobscured, and no increase of exposure is necessary. The objection to this system is that if the screens are placed outside they are not easy to manipulate, and, moreover, offer considerable resistance to a strong wind, while, if placed inside, they are liable to interfere with the easy working of the ordinary blinds unless the studio has a lofty roof. For this reason the simpler method of diffusing the light is now more generally adopted. Operators who are experienced in artificial light work will find it quite easy to use direct sun-light through a white blind or similar device.

The selection of a suitable diffusing medium is an important matter, as many devices have been suggested and some of these are noticeably inferior to others. Glazing the studio with ground glass seems to offer the easiest solution of the problem, but in practice it is the least satisfactory; although it prevents sharply-cast shadows it does little to minimise the general glare. A better way is to stipple the glass with zinc white paint, but still better is to employ a movable screen of translucent material, such as tracing paper or cloth or waxed paper. These control the light effectually, and can be dispensed with on dull days or after the sunlight has passed away. If the festoon curtains, which we have so often advocated, are used it will be found that the white nainsook section renders any further diffuser unnecessary, all that needs to be done is to see that the white curtains are quite clean.

Inside the studio all unnecessary light should be

screened off by backgrounds or some similar device, so that the space between the lens and the sitter is well shaded. A necessary, but often neglected, precaution is to shade the lens, especially if it be of the modern anastigmat type. The best way of doing this is to erect a framework either upon the camera itself or upon the stand, and to cover this with a curtain, which serves also as a focussing cloth. A projection of eighteen inches from the camera front is not too much for a 12 x 10 camera. Two small curtains on the front of the frame will be of great service when working against the light, as these can be adjusted so as to cut off all light not intended to reach the plate.

In sunlit studios the colour of the walls should be appreciably darker than when working with a north light, a rather dark grey or sage green being most suitable. Care should also be taken to avoid reflections from the floor, rugs being laid over polished linoleum or wood.

In working with such a diffused light as we have described it is quite easy to obtain portraits with strong contrast by reducing the area of illumination and bringing the sitter close up to it. If a white curtain brightly lighted by the sun is the source of illumination, it can be handled in very much the same way as an electric-light installation, and one accustomed to the latter will find no difficulty in getting any desired lighting.

The apparatus used in a brightly-lighted studio requires a little more attention than is usually given to it, as there is more risk of interior reflections causing fog. The lens tube and hood should be kept a good dead black; for large lenses velvet is a better lining than varnish. The interior of the bellows, and particularly the edges of any woodwork should be treated with a dead black varnish. The cases and frames of exposing shutters should also be looked to, as these may reflect unwanted light upon the plate. These precautions are not out of place in any studio, but they are exceptionally desirable when there is any tendency to flatness in the lighting.

THE SEASONAL PROBLEM IN "AMATEUR FINISHING."

For the man with the requisite knowledge and capital, amateur finishing should prove an exceptionally good line.

But, like everything else, "amateur finishing" has a characteristic that is not exactly an unmixed blessing. It fluctuates. From next door to zero at the New Year, it rises to unmanageable heights by August or September, to drop back to insignificance in a couple of months. The employer's problem of "What to do with surplus staff" becomes "How to obtain competent help," and with employees it is a case of "How to find or keep a job" becoming "How to see a bit of daylight."

Now the present is a significant time for the photographer who caters for this business. Dealers, chemists, and others who specialise in the line are already getting busy putting things shipshape for the coming season, and I have no doubt that those photographers who have previously undertaken this kind of business are doing the same. Considering the amount of work that should be done between now and Christmas it is quite likely that more studios will branch out on developing and printing this year, especially in view of the abnormal slackness in portraiture that is being experienced in many parts.

But I am not concerned at present with new and prospective exponents of the business, and I won't attempt to describe here the equipment and system necessary for success. It has already been done and information in detail is always to hand from manufacturers who are interested in the supply of apparatus and materials. I will therefore pass on with the hint that now—and not May or June—is the better time to get all into working order.

From a fairly deep consideration of the rush problem I am convinced that it might be greatly alleviated, if not totally eliminated, by application of certain business tactics. In this line, as in others, there can always be found a firm or an individual willing to do work at ridiculously low charges and to turn it out in impossible time. It is a mistake to fear the opposition of such people unless it so happens that they can do better work than we can, and in that case well, we had better quit. But rush work at cut prices will not approach the standard of any respectable workshop, and it can be ignored. There is a kind of customer capable of expecting a film developed and printed for about a shilling, and that between Saturday evening and Monday morning. But why cater for them? There is a demand for better work than this, and my argument is that by catering for the latter at the expense of the former—instead of the reverse process—we may solve the fluctuation problem.

The main items of amateur finishing are the development of exposed spools and the printing of the same in a mechanical stereotyped manner on gaslight paper. The bulk of the printing is untoned black and white, most of it is untrimmed; much is unmasked, and little or none is spotted or mounted. This is the kind of work that invites rush and fluctuation. On the other hand, work printed with an eye to pictorialism—selection of negatives' best parts, straightening, elimination of waste and faulty passages, etc.—toned, tinted, spotted and mounted might find a more steady market at more respectable prices. The well-known type of amateur print is well worth doing if done well, but it should not be the one and only style shown or advertised. With superior lines in hand, the common style could at any time be dropped to ease an overload. By way of example we might start off at the present time with the following lines:—

Exposures developed, one grade, standard.
Negatives printed, two grades, ordinary and double-weight (toned if desired).
Prints mounted, selected styles offered.
Enlargements, selected styles offered

At first there might be practically no demand for anything but ordinary developing and printing, but the others would follow gradually, and in July or August, instead of starting overtime and struggling with a smother of cheap work, it would be an easy, pleasant and dignified thing to notify the public that "Owing to the great demand for our Quality Printing we are reluctantly compelled to withdraw our other styles for the present," etc., etc.

The result of such a move, if carefully engineered, would be that instead of doing about 10,000 prints (on overtime and against time) for £100 income, it would only be necessary to do about 500 double-weight, warm black or toned prints on which the profit in £100 might be greater. Considering the release from working under pressure, it certainly should be well on the right side. Consider the thin edge of the wedge. We commence merely by dropping thin, unmounted prints. The standard style of printing becomes masked and trimmed work on double weight. This means giving the customer much better value, as anyone who is in the habit of carrying snapshots about in his wallet or in her satchel—will agree. It should also prove an advertisement for the photographer. Such prints are worth all of 35 to 50 per cent. more than

the ordinary article, but they do not cost 20 per cent. more to produce, as though the double-weight paper is 20 per cent. extra, the chemicals, light, labour and overhead costs are approximately the same. Therefore if we do double-weight prints exclusively at 35 per cent. over, say, the Kodak prices, a bigger margin of profit will be obtained, and we can afford to dispense with overwork.

The production of good substantial work in preference to shoddy has another beneficial result. It encourages the right kind of customer rather than the camera-mad film destructor, who is often more of a nuisance than he (or she) is worth. It may be argued that film wasters spend an appreciable sum on photography, and so from a business point of view should not be ignored. I can admit the truth in this, but still contend that the more serious and discriminating camera-users among the public are likely to be the finisher's best customers if properly catered for. I am not referring to the genuine amateur, whose interest will compel him to do his own printing, etc., but to a type of camera-user who comes midway between him and the film destructor and has something in common with both. Anyone who is familiar with the trade will recognise the customer who combines the amateur's keen interest with the button-presser's desire to have the finishing done by somebody else; who is responsible for much good photography, and spends quite a lot on it. This is the customer who can be kept and cultivated. He may not, as a class, create a demand for millions of prints, but what he does want he will want good, and he does not expire with the summer holidays.

As with double-weight prints—or any other simple style calculated to benefit both customer and producer—so with toned, tinted, and mounted work. The better the class of work done, the less work and the greater profit and reputation. Enlargements and lantern slides are in demand from customers' negatives, and their supply can do much to level out the twelve months' business.

Here again quality should pay better than quantity. Anybody can make an "enlargement" or a "slide" from a snapshot film for a shilling or so, but such work is no advertisement, and can hardly bring in a decent profit unless done wholesale. The making of a "picture," or a slide that will threw a "picture" on to the screen, is a different thing—a thing that will bring a reputation to the house capable of it, and such work finds a demand at fair prices among the better classes of camera-users.

And these lines lead to others. Satisfied customers bring all kinds of photography to the man who can do really good "amateur finishing." They are the public, and to get a reputation among the public is no mean or empty achievement, and I am inclined to believe that a reputation for "amateur finishing" is a broader and more fertile thing than a reputation restricted solely to studio work.

THERMIT.

SODA CARBONATE AND THE MONOMET WATKINS FACTOR.

IN the course of an investigation on which we are eugaged we have had occasion to examine the effect of alteration of carbonate concentration on the behaviour of Monomet. Some of our results, since they have a direct bearing on the subject of factorial development—a matter which is at present engaging the attention of photographers—appear to be of sufficient interest to warrant publication apart from the larger investigation.

A stock solution was made by mixing two solutions containing respectively 3.2 gms. of Monomet and 10 gms. of anhydrous sodium sulphite in 100 c.c.s. of solution. The mixture of the two solutions gave a thin cream of suspended amidocresol base of very great stability, owing to the preservative action of the sulphite present. Development tests were made on Imperial special sensitive plates which had been appropriately exposed (200 candle-metre-seconds) behind a step wedge.

For the first test, 10 c.c.s. of the monomet base mixture were diluted with 90 c.c.s. of water, solution of the base occurring rapidly at this dilution. When poured on the exposed plate the image appeared in 5 minutes, and development was allowed to proceed for 50 minutes at 65 deg. F. The result was a beautifully graduated, clean negative with densities rising from 0.25 to 1.3. A second plate was treated with 100 c.c.s. of developer containing 10 c.c.s. "stock" solution and 2 c.c.s. of normal (*i.e.*, 5.3 per cent Na_2CO_3) sodium carbonate solution The image appeared in 76 seconds, and development was conducted for 8 minutes. The resulting negative was exceedingly thin, the greatest density being only 0.8 with a developer containing 5 c.c.s. of carbonate solution, the time of appearance was 18 seconds, and 8 minutes development produced a normal negative, with densities ranging from 0.48 to 1.5. Further increase of the carbonate concentration, up to 40 c.c.s. of the normal solution in 100 c.c.s. developer, gradually lowered the time of appearance to 7 seconds without any increase in the densities; moreover, with 20 c.c.s. and 40 c.c.s. carbonate solution, the plates were appreciably fogged. On calculating the development factors, the following interesting results were obtained:—

	Sol. of Na_2CO_3 per 100 c.c.	Normality of Na_2CO_3.	Time of of appearance.	Total time of development.	Range of densities.
(1) ..	None.	—	5 mins.	50 mins.	0.25—1.3
(2) ..	0.106	N/50	76 secs.	8 „	0.4 —0.8
(3) ..	0.265	N/20	18 „	8 „	0.40—1.5
(4) ..	0.53	N/10	12 „	8 „	0.5 —1.5
(5) ..	1.06	N/5	9 „	8 „	0.55—1.5
(6) ..	2.12	2N/5	7 „	8 „	0.53—1.5

Dividing time of appearance into total time, we get the factors:—

(1) Factor ..	10	(4) Factor ..	40
(2) „ ..	65	(5) „ ..	53
(3) „ ..	26	(6) „ ..	69

It appears, therefore, that the best formula for a Monomet-carbonate developer will be the following:—

Monomet	1.6 gms.
Sodium sulphite (anhydrous)	5.0 gms.
Sodium carbonate (anhydrous)	5.3 gms.
Water to	1,000 c.c.s.

To enhance its keeping qualities, the Monomet and sulphite may be dissolved in 500 c.c.s. of water (the solution will not be quite free from suspended base), and the carbonate in a separate 500 c.c.s. equal volumes of the two solutions being mixed just before use. The normal factor for such a developer will be 35 to 40.

One of the most interesting points noticed was that of the suitability of Monomet, in concentrations up to 2 grams per 1,000 c.c.s. with three times its weight of anhydrous sodium sulphite, for tank development. At a temperature of 65 deg. F., development will be complete in from 1 to 2 hours,

according to the brand of plate and the degree of contrast desired. An appropriate formula would be:—

Monomet	2 gms.
Sodium sulphite (anhydrous)	6 gms.
Water to	1,000 c.c.s.

the Monomet and sulphite being dissolved separately, and the cold solutions mixed.

Whilst it is well known that the concentration of carbonate alkali has considerable influence on the developing characteristics of the poly-hydroxy-benzenes (hydroquinone, pyro, etc.), the above figures, indicating the concentration of carbonate alkali above which (in conjunction with an amidophenol) the rate of development (but not the time of appearance) is unaltered, constitute, as far as we are aware, new knowledge of interest to the advocates of factorial development.

GRAIN SIZE AND SENSITOMETRIC PROPERTIES OF EMULSIONS.

(A Communication from the Research Laboratory of the Eastman Kodak Company.)

Although the existence of some relation between size of grains in a photographic emulsion and the sensitiveness of the emulsion was accepted early[1], little or no attention appears to have been paid to the variation in grain size in one and the same emulsion or layer, as a factor in the photographic properties. Attention was first called to this by C. E. K. Mees[2], in a paper on "The Physics of the Photographic Process." He considers that, "inasmuch as the emulsions are not homogeneous, but each emulsion will contain grains of all sizes, the sensitiveness will depend upon the distribution of the different sizes of grains, as also will the shape of the plate curve, this plate curve being the relation between density and logarithmic exposure." Further, he states "the shape of this curve depends to a considerable extent on the distribution of the different sizes of grains in the emulsion. With a homogeneous emulsion we should have a simple curve with a short over- and under-exposure portion, as shown in fig. 1, and by adjusting the

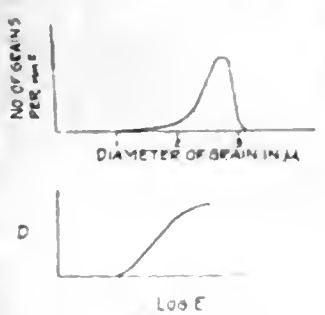

Fig. 1.

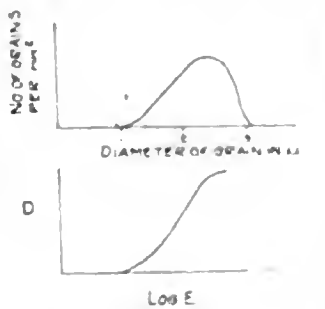

Fig. 2.

sizes of grain so that there is a sufficient number of grains distributed around the mean, we can diminish the size of the under exposure position to obtain a longer straight line (fig 2) We can therefore form a mental picture of the relation between the distributions of the grain and the sensitiveness curve." The author points out that up to that time there had been very little experimental work on this subject, and that the relations suggested were speculative. It appears that the main suggestion is that a proportionality exists between the degree of heterogeneity of the grains, otherwise the breadth of the frequency curve, and the latitude of the plate or emulsion. It is stated that any such considerations are to be regarded as limited to high-speed emulsions.

In this connection we should point out that a first result of our experimental work is to show that the frequency curve alone is of less value in relation to the sensitometric curve than the projective area curve obtained by plotting the product of frequency by the projective area of grains of a given class against the corresponding classes. This will be discussed more fully later. It seems desirable, however, to call attention to this point at this stage.

Experimental investigation of the problem was begun in June, 1919; later papers give account of the results. Meanwhile there has appeared a Paper by Slade and Higson[3], and another by T. Svedberg[4], in which the same problem is envisaged.

Slade and Higson state that "under ordinary conditions of exposure, the shape of the plate curve (as determined by Hurter and Driffield's method) is dependent on:

"(1) The relation of the different sizes of grains in the plate to each other and the quantity of each present.

"(2) The thickness and opacity of the film.

"(3) The time and method of development (though on 'infinite' development almost the same result is obtained whatever the developer and however much bromide it contains)."

They emphasise the importance of the first factor, and show by H and D curves the difference between a plate with grains nearly of the same size and a plate with grains of mixed sizes. They also give photomicrographs, which illustrate the two kinds of plates. The plates with grains of nearly uniform size have much steeper curves than those with mixed grains.

Their results are obviously only semi-quantitative, as no measurement of the dispersity of the silver halides is given. From the curves it appears that, according to their view, γ_∞ is increased by homogensing the grain, and latitude, i.e., the projection of the straight line part of the plate curve is diminished. In partial agreement with this is Lüppo-Cramer's[5] statement that plates of homogeneous grains, prepared by after-peptisation of a finished emulsion show a much earlier reversal period than plates with non-uniform grain.

In a quite recent paper by F. E. Ross[6], of this Laboratory, on the relation between photographic density and exposure, the author develops a new theoretical formula for the characteristic curve. It is pointed out that many formulæ can be constructed depending upon particular assumptions of the following types:—

a. Relative frequency of grains of varying size.

b. Relative sensitiveness of grains of varying size.

c. Variation of grain sensitiveness with light-intensity and wave-length for each class of grain.

d. Ratio of inert to active grains, depending on grain size.

e. Number of layers of silver halide.

f. Opacity of emulsion and its variation with wave-length.

The author points out that data for weighing these assumptions

1. J. Gaedicke, Eder's Jahrbuch, p. 309 (1906); Eder's Handbuch, 3, 66 (1903).
A. P. H. Trivelli, in 1911 (Z. wiss. Phot. 9, 168), had considered a certain relationship to exist between the size of grains of silver halide and the energy absorption when light falls upon them. Lüppo-Cramer (Phot Korr. 47, 468) in the same year, stated that size of grain is concurrent with sensitiveness, and is limited by visible granularity of the negative. Koch and du Prel (Physik. Z. 17, 536), in 1916, also made some important observations tending to show that the so-called coarse-grained plates are not necessarily the most sensitive. Recently, Slade and Foy (Proc. Roy. Soc. A97, 181 (1920)) have made some careful spectrophotometric measurements of the absorption of light by silver bromide. Further, a very recent article by R. E. Slade and G. L. Higson (Proc. Roy. Soc. A91, 154 (1920)) deals with the action of light on a dilute emulsion, which was said to have grains of uniform size, and was one layer thick. Others have likewise given thought to the questions of the size of grain and sensitiveness, and of the absorption of light by the silver halides. A more complete bibliography of this subject will be presented in a forthcoming monograph on the photographic theory by A. P. H. Trivelli and S. E. Sheppard
2. C. E. K. Mees, J. Franklin Inst., 179, 141 (1915)
3. R. E. Slade and G. L. Higson, Phot. J., 59, 260 (1919).
4. T. Svedberg, Z. wiss. Phot. 20, 36 (1920).
5. Lüppo-Cramer, "Photographische Probleme," Halle, 1907.
6. On the Relation between Photographic Density, Light-Intensity, and Exposure Time, by F. E. Ross, Journal of the Optical Society of America, 5, 256 (1920).

severally are lacking, hence, it is unprofitable to develop a formula on any but the simplest assumptions. As these he takes:—

1. All grains in an emulsion are divisible into n groups, each group as a whole obeying the mass action law.[7]

2. The silver mass the same for each group.

3. The sensitivity factor of the groups arranged in geometrical progression. This regards as equivalent true sensitivity difference (inherent) and apparent sensitivity differences (topical), due to thickness of emulsion. This equivalence is possible on account of the reciprocal equivalence of intensity and absorption-coefficient in a layer.

From these assumptions a formula is derived. Calling d_m the maximum density for infinite exposure (reversal neglected), k the sensitivity factor, r the common ratio of the sensitivities of the groups, the equation is obtained

$$D = d_m\left(1 - \frac{1}{n}\sum_{s=0}^{s=n-1} e^{-Kr^s It}\right)$$

$$\frac{dx}{dt} = kI\,(A - x).$$

Taking values $r = 1/2$, and $n = 1, 2, \ldots 10$, the field of practical emulsions should be well covered. A series of typical curves thus obtained is shown in fig. 3.

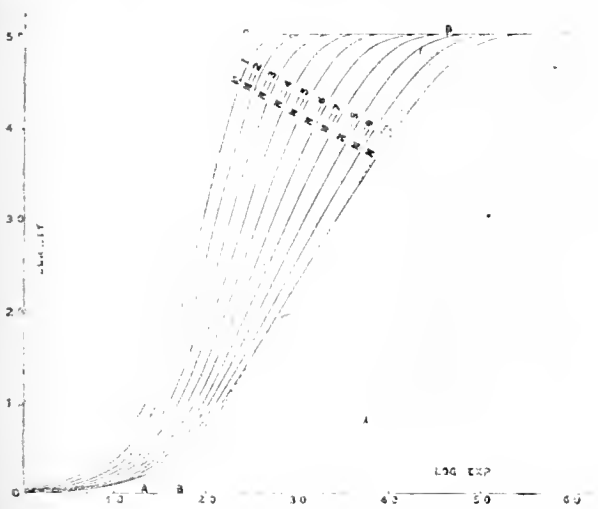

Fig. 3.

Now, it will be noticed that for increasing values of n the slope, or γ_∞, becomes less and the straight line portion longer. Instead of the H. and D. latitude Ross takes the "range," as antilog of the projection of the line A A' or B B' on the exposure axis, as measure of the reproducing power of an emulsion. The "range" increases with n, as shown in following table:—

n	*Range.*
1	15
2	17
4	35
8	290
10	1,000

Although n does not refer explicity to number of classes of different sizes, it would do so (*a*) if these had varying sensibilities, (*b*) if opacities were constsnt. In this case, Ross's equation agrees partly with Mees's hypothesis, that increasing grain heterogeneity increases latitude[8], but also agrees with Higson and Slade's contention that more homogeneous grained emulsions have steeper curves.

We may point out here, anticipating certain results given in a later paper, that the influence of size of grains is not symmetrical in respect of their effect on exposure conditions (light-intensity gradient) and development results (development factor). A great number of very small grains may contribute little on development to effective density, but they may very markedly affect the turbidity and opacity of the plate or film; hence their effect on the characteristic curve is not revealed by the density after development.

Slade and Higson were apparently ignorant of Mees's previous paper, and this is also the case with Svedberg. The latter considers that the problem at issue may be treated as, generally, relation of light-sensitiveness to size of grain, and specifically, the four following cases of this:—

(1) Every single grain has the characteristic curve of the plate.

(2) For every class of grains of nearly the same size in the emulsion there is a distinct curve.

(3) The characteristic curve is only shown by emulsions with non-uniform grain.

(4) The relation between density and exposure expressed in the plate curve is a consequence of inhomogeneity of the photo-chemical illumination inside the photographic layer.

The last case is discounted largely by results with very thin layers previously obtained by Lüppo-Cramer and W. Scheffer,[9] and confirmed by Svedberg. As to the first case, Svedberg concludes, in agreement with Sheppard and Mees, that "reactivity" (rate of reduction) of the grain depends on exposure, but not absolute reducibility. Hence, the problem falls back on the second and third cases. It is pointed out that these require statistics of distribution of size in relation to exposure on ultimate development. Instead of measuring the reduced grains of distorted appearance, Svedberg has applied the method of difference determination. Statistical measurements of grain size (or dispersity) are made first in the unexposed but developed emulsion, after treatment with a silver solvent, then they are made for a series of exposures. From these measurements two important diagrams are obtained, namely (*a*) the curves connecting exposure and percentage reduced grains for each order of magnitude of the grains (*b*) curves showing relation between size of grain and percentage made reducible after a certain exposure.

The first type of curve is comparable with the characteristic curve (since the number of grains is a factor in density). The second gives the relation of light-sensitiveness to size of grain. The determination and division of sizes of residual grains were made by direct projection and microphotography of the exposed, developed layers of very thinly coated much diluted emulsion,[10] after dissolving the developed grains. They were photographed at 1,000 diameters, and then copied on paper at 4x, giving 4,000x in all, and the mean *diameters* of circular grains were determined, and the areas of the polyhedral grains were found by means of a millimetre network. All sizes were then reduced to projective areas, and divided into four classes of magnitudes.

The results are shown in the curves in figs. 4 and 5.

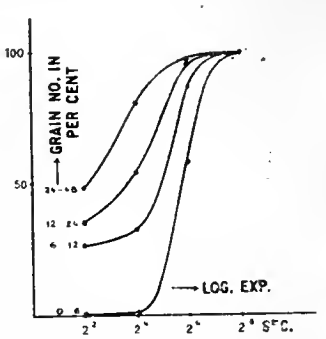

Fig. 4.

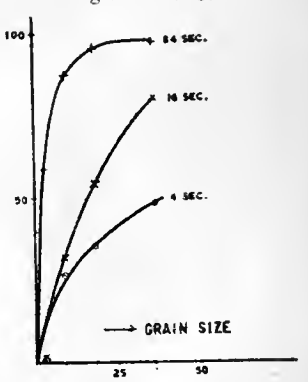

Fig. 5.

From this it appears that every class of grains has its own characteristic curve; D, however, would be proportional to Pn, where n is the number of grains, P the photometric constant or factor. Now at present we do not know precisely the function $D = f(N,S)$, where N = the number of grains per cubic mm., S = the magnitude. Assuming $D_\infty N$, we have $D = Nf(S)$, and $f(S)$ remains to be determined. The only estimation we have of this at present is that of Higson,[11] who gives a relation between size of developed grain, and P, the photometric constant. If we assume that the size of the developed grain, as a first approximation, is proportional to that of the original silver bromide grain, we can use Higson's values to calculate from Svedberg's data the actual D log E curves for his four classes of grains.

Table I. gives the mean projective areas of the undeveloped grains for Svedberg's four classes and also these areas multiplied

7. That is, the law that rate of reaction is proportional to mass of material unchanged.

8. Latitude being analogous to Ross's range.

9. W. Scheffer, Z. Elektroch., *14*, 489 (1908).

10. First should be determined the effect of dilution and thickness of coating on the plate curve.

11. G. I. Higson, Phot. J. *60*, 160 (1920)

by four.[12] The corresponding diameters and photometric constants calculated from these are likewise given.

Svedberg gives no data for the number of fogged grains, so that these could not be taken into account in the tables. In Table II. are shown (see also fig. 6) the number of developed grains (exclusive of fogged grains as stated) for each exposure, together with densities to correspond (using 4A as the projective area for the developed grain), and also the additive or total densities. These total densities, it will be seen, by comparison with the total densities for the plate given in Svedberg's paper, as shown in fig. 7 and Table III., are in the neighbourhood of four times higher than those of the latter, whereas, if Higson's method of calculation is correct and if Svedberg's method is reliable, the values should agree.

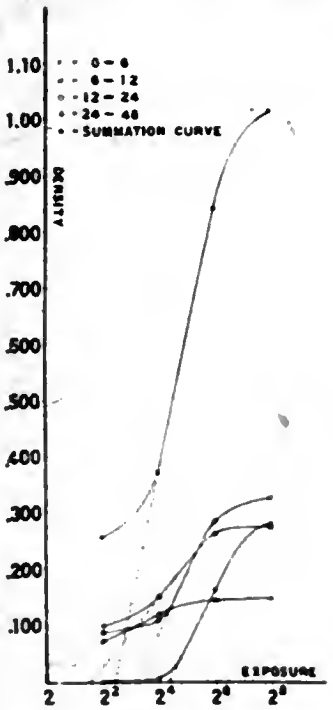

Fig. 6.

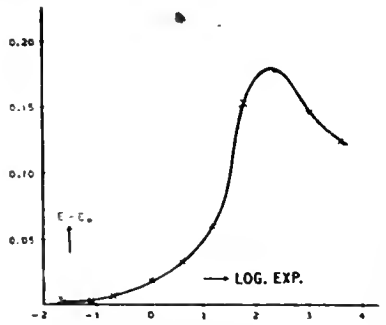

Fig. 7.

Fig. 1 from Svedberg's Paper.

TABLE III.

Time of exposure in seconds.	Density (= extinction co-efficient). Total density.	Density, less fog.
0	0.105 (= $_0$)	0
0.02	0.109	0.004
0.08	0.109	0.004
0.2	0.112	0.007
1	0.124	0.019
4	0.138	0.033
16	0.165	0.060
64	0.258	0.153
256	0.283	0.178
1024	0.250	0.145
4096	0.229	0.124

The most plausible explanation for this large discrepancy appears to be a fallacy in Higson's assumption that in general the developed silver grain has twice the diameter of the original bromide grain (i.e., 4 times the area). It is known, for instance that certain developers, such as phenylenediamine and hydrazine give developed grains considerably smaller than the original grain.

12. According to Higson, the developed silver grain is larger than the original bromide particle by this amount.

Of course, it may be argued that these developers are not capable of giving complete development, or perhaps they cause part of the silver to be dissolved. However that may be, there does not appear to be sufficient experimental evidence for Higson's assumption. Work on this point, namely, the determination of the ratio of the size of developed to undeveloped grain for various developers is much to be desired, and is about to be investigated in this laboratory by Mr. A. P. H. Trivelli.

If we assume that the fully developed grains in Svedberg's work were of about the same size as the undeveloped grains (some previous observations by one of us on the size ratio of developed to undeveloped grains using a developer similar to that of Svedberg substantiate this assumption), then the density values calculated from Svedberg's data on this basis, give D-log E values very close to those of the latter, as shown by comparison of fig. 8 and Table IV. with fig. 5 and Table III. above.

Our calculations are based on the mean projective areas given by Svedberg. The maximum and minimum values of his four classes, particularly the larger sizes, which are the most important, are quite wide apart, so that the agreement just shown is all the more striking.

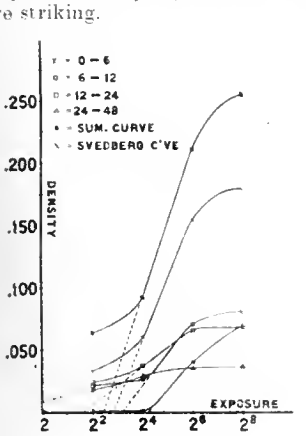

Fig. 8.

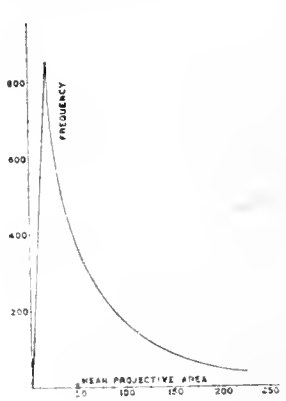

Fig. 9.

D-log E curve from Table IV.

Svedberg's work on solarisation and hydrogen peroxide action in this connection need not be discussed at present.

We reproduce herewith the size frequency distribution curve (fig. 9) plotted from Svedberg's data: this curve, of course, does not include fog grains.

Our work, which was commenced before the papers of Slade and Higson, and of Svedberg, appeared, has as its object the investigation of the relation of grain, in the statistical sense, or of dispersity, to the sensitometric properties of emulsions. This requires methods of assay and determination of the size frequency curves. A discussion of the methods already developed in this direction by ourselves and others will be published shortly.

E. P. Wightman.
S. E. Sheppard.

RULE FOR FINDING DIAGONAL OF PLATE.

It is often required to know the exact diagonal of a plate, as when obtaining a condenser for enlarging, or choosing a lens of the maximum focus desirable for all-round work. The diagonals of the more usual sizes of plates are to be found in tables, such as that given in the "B.J.A.," as a note to the "Table of View-Angles"; but for odd or special sizes one has to make a practical test, either by drawing a rectangle of the dimensions in question and bisecting it from opposite corners, or by measuring across the plate itself. Both of the latter methods are liable to error unless carried out very carefully.

There is, however, an accurate and simple rule for finding the diagonal of any rectangle or square, which, though perhaps familiar to the mathematician, will probably be new to most photographers. It is as follows:—Let A and B equal the length of two adjoining sides of the rectangle, then the diagonal will be equal to the square root of the squares of A and B added together. Or, to express it as a formula, the diagonal = $\sqrt{A^2+B^2}$.

For example, what is the diagonal of a Continental plate measuring 18 cm. by 24 cm.? Here, the square of 18 is 324, and the square of 24 is 576. Adding together 324 and 576, we get 900, and the square root of 900 is, of course, 30; so that 30 cm. is the required diagonal, practically equivalent to 11.8 in.

Or, to give another instance, what is the diagonal of a 5 in. by 3½ in. plate? (This is one of Mr. Watkins' suggested logical sizes.) Here, the square of 5 is 25, and the square of 3½ is 12¼. Adding together 25 and 12¼, the total is 37¼, and the square of 37.25 is 6.103, so that the required diagonal is approximately 6.1 in.

By many people the extraction of a square root is regarded with a quite uncalled-for amount of awe. Those, however, who are not acquainted with the method, or who wish to save trouble, can easily refer to the tables of square roots to be found in ready-reckoners, etc. These only deal with whole numbers, but that is usually near enough. Thus in the example just quoted, on looking up 37 in such a table, the square root is found to be 6.037.

For those who like proof of a rule, it may be stated that the foregoing depends on Euclid's well-known proposition that the area of a square erected on the hypotenuse of a right-angled triangle is equal to the combined area of the squares on the other two sides. The diagonal of a rectangle is obviously the hypotenuse of two identical right-angled triangles, hence its length must be equal to the square root of the added squares of the two other sides of either triangle, that is, two adjoining sides of the rectangle.

It may be remarked that the rule is also useful occasionally for testing the accuracy of a set-square, or for verifying the truthful adjustment of the gauge in a guillotine cutter, or the angles of a trimming glass. This can be done by measuring two edges or sides at a right angle, and then noting whether or not a diagonal connecting the ends agrees in length with that calculated.

A. Lockett.

THE GORSKY PROCESS OF COLOUR CINEMATOGRAPHY.

A private view was held in London last week of a short length of film, the first to be shown, prepared by the process of colour cinematography, which has been worked out by Professor S. M. Procoudine-Gorsky. The film, taken on the Riviera in September last, had as its subject a slight incident of matrimonial misunderstandings. The eternal triangle of the cinema theatres aparently is an obsession even of the technical experimenter in cinematography. So far as the technical result is concerned, it was explained that the film had been taken with the object of showing the practicability of the process, and therefore had been made at a stage of its development at which the causes of certain minor defects had still to be eliminated, whilst the mechanical equipment for the printing of the coloured films was that of the experimental laboratory, and not of the factory. With these allowances to be made, it was not the easiest matter to form a definite opinion of the process. The film was certainly very transparent, yielding a bright picture on the screen, and many of the textures, and particularly flesh tones, were well rendered.

Scarcely any technical particulars of the process are available, but it is stated that the negative is made at triple speed, and, presumably, that each successive series of three pictures on the negative is used as the set of colour-sensation negatives. From each of these three a separate colour impression is produced, and the three assembled in register, so that the film is a series of complete colour pictures on a film which can be shown in any cinematograph projector. It would seem that the several colour impressions are produced by a mordanting process of dye-toning. But presuming that the foregoing is a description of the process in general terms, it seems somewhat difficult to understand in what way identity of the images in three successive picture sections is obtained. If the subject is in rapid movement, it would seem inevitable that the image must differ from one picture section to another, even when taken at triple speed, a defect which would give rise to want of registration, and thus to the colour fringing, which is the rock on which many processes of colour cinematography have foundered. It may be that we are not fully informed of the basis of Professor Gorsky's process, which, at a luncheon following the demonstration, was described by Mr. Sanger-Shepherd as being a sound one, and as having yielded a film parts of which were technically perfect. It is clear, however, that Professor Gorsky has progressed some way towards the goal which has been his ideal for many years past, and we wish him all success in his further progress.

Photo-Mechanical Notes.

Reversal Methods for Photo-Engraving.

It is not an uncommon occurrence in photo. engraving for line blocks to be reversed, *i.e.*, the black lines are required to print as white lines on a black background, and by use of one of the following methods the operation can be easily and quickly performed without having to resort to the making of a positive. In all the cases given the negative is made as usual.

Method I.

The negative is printed on the zinc plate by the albumen method and developed out in the usual way. After drying, the plate is coated with the fish glue or enameline solution, dried and exposed without putting in a frame, by standing it up to the light. When the exposure is finished, the plate is dyed up and dried off, when the ink image can be removed by rubbing it with cotton wool moistened with turpentine. The plate is burnt in, and after cooling is ready for etching.

Method II.

An albumen print is prepared in the ordinary way and given a good pass through the graining bath. After drying it, the plate is rolled up solid with etching ink and placed in the following solution:—

Water	20 ozs.	...	600 c.c.
Hydrochloric acid (pure)	½ oz.	...	15 c.c.

This solution attacks the albumen under the original work and causes it to wash away, leaving the bare metal, whilst the ink applied by the second rolling up is left intact.

Method III.

A print is made by the enameline process, but is not burnt in. After the plate has been dried, it is rolled up with soft letterpress ink and dusted in with powdered bitumen. The plate is then placed in a 5 per cent. nitric acid bath, which penetrates the film causing the fish-glue to leave the metal. This action is assisted by gentle rubbing. When the plate is dry it is heated to set the ink and bitumen.

Method IV.

Shellac	1 oz.	..	30 c.c.s.
Dragon's blood	60 grs.	..	4 gms.
Industrial spirit	10 ozs.	..	300 c.c.s.

An albumen print is made, but not dusted with bitumen, and after flowing over with plain spirit, it is flowed over with the above solution and whirled dry. The reversed image is obtained by washing out the plate with benzole.

Method V.

This method is known as the Vandyke process and can be used for printing directly from the original as well as from a negative, provided in the former the lines are drawn or printed in firm black ink on clean paper.

The zinc plate is coated with the following solution and exposed behind the original or negative:—

Fish glue	2½ ozs.	..	75 c.c.s.
Ammonium bichromate ..	½ oz.	..	15 gms.
Ammonia 880	30 minims		2 c.c.s.
Water	10 ozs.	..	300 c.c.s.

After the exposure is made the plate is developed in water as in the case of an enameline print and the surface gently but thoroughly rubbed with a creamy paste of magnesium carbonate. The latter should be well rubbed down on a piece of glass or zinc to ensure it is free from grit, which would scratch the work. The print is rinsed under the tap and passed through the following graining bath, washed well and dried over a flame:—

Nitric acid	½ oz.	..	7 c.c.s.
Alum	60 grs.	..	4 gms.
Water	40 ozs.	..	1,200 c.c.s.

The plate is now rolled up with the following ink applied thinly:—

A.	Litho chalk ink	6 parts }
	Stick litho ink	2 parts } Mix by heating.
	Hard copper plate transfer ink ..	2 parts }
B.	Bitumen	1 part } Dissolve in chloroform
	Yellow lump resin	1 part } and benzole mixed

Thoroughly mix A and when cooling gradually add B with constant stirring. For use thin out a small quantity of the ink with turps on a slab and roll up plate, which should then have a thin grey film of ink over it. The plate is now warmed to set the ink, and when cool is placed in clean water for 2 or 3 minutes, when it is gently rubbed with cotton wool to remove the glue and ink upon it, leaving the ink adhering to the bare metal.

If the glue is difficult to remove, soak for a short period in a 1 to 400 bath of sulphuric acid. After the glue has been removed, dry and treat as ordinary line work.—E. L. Turner.

Multi Reproductions on One Negative.

Small blocks of different sizes are frequently required from an original or originals. One method is to take separate negatives of the required size and then strip the film to a large sheet of glass, and thus enable the etcher to treat them as one plate, which is subsequently cut up and mounted. By employing the following method only one negative is made, and no stripping is necessary, thus saving considerable time. To take four exposures on one plate, cut out an L shape mask of stiff card, as shown in fig. 1, the dimensions depending upon the size of plate to be used. Place the mask in the half tone screen holder as shown at 1. Focus the original and adjust the image so that it falls in the cut-out portion and make the first exposure. After this exposure, close the darkslide and remove from camera. Turn the mask as shown at 2, with the cut-out portion to the right. Move the original and re-adjust the focus, replace the slide and expose. The third and fourth exposures are treated in a similar way, only the mask is inverted, as shown, with the openings as seen at 3 for the third exposure. For the fourth exposure the mask is turned round with the cut-out portion as seen at 4, thus completing the four exposures.

Six exposures can be obtained by cutting two masks as shown

in figs. 2 and 3. It will be noticed that fig. 2 is longer than fig. 1. The procedure is the same as when using fig. 1 for the four exposures. The fifth and sixth exposures are made through fig. 3, turning from right to left. The diagram will explain the method of using these masks.

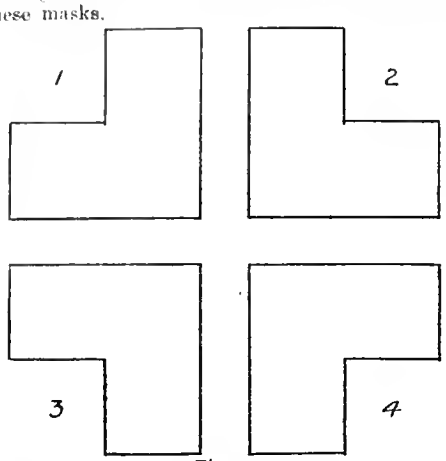

Fig. 1.

A mask with which eight exposures can be made, and which anyone of ordinary ability can construct, is shown in fig. 4. The shaded portion is a piece of cord that covers up half the opening, and works in the slides *a* and *b*, so that either half can be covered. Fig. 5 shows in section the sliders in which the card is pushed up

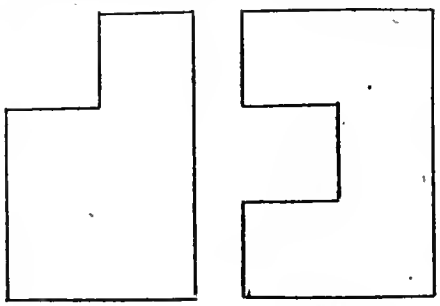

Fig. 2. Fig. 3

and down. The first exposure is made through the top left-hand opening, with the card over the lower portion. The next exposure is through the lower portion, the card being pushed up for the purpose. The mask is then turned so that the opening is on the right side, the same operations being repeated. Four exposures

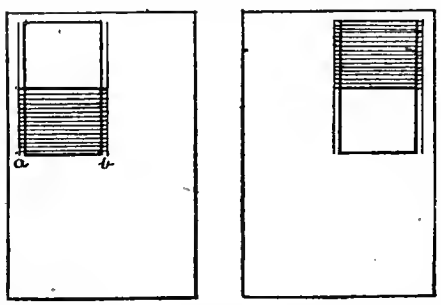

Fig. 4.

are thus obtained. The remaining four are made by inverting the card so that the openings are at the bottom of the plate, thus making the eight exposures.

A little thought and ingenuity will suggest how by adding additional covers even 12 or 16 exposures can be obtained on one

Fig. 5

plate. If the wet collodion process is used for negative making, and the exposures exceed eight minutes, it is sometimes advisable to re-dip the plate in the silver bath before developing, having previously well drained the plate from an excess of silver solution.

W. J. S.

FORTHCOMING EXHIBITIONS.

March 14 to 26.—Dennistoun Amateur Photographic Association. Hon. Secretary, Wm. F. Macpherson, 152, Craigpark, Dennistoun.

April 13 to 23.—Portsmouth Camera Club. Latest date for entries March 31. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

April 15 to 23.—Professional Photographers' Association, at the Photographic Fair. Horticultural Hall, Westminster, S.W. Latest date for entries, April 7. Hon. Secretaries (Correspondence), Marcus Adams, 43, Dover Street, Piccadilly, London, W.1; (Exhibits), R. N. Speaight, 157, New Bond Street, London, W.1.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Latest date for entries, April 16. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs

April 28 to 30.—Nottingham and Notts. Photographic Society. Latest date for entries, April 13. Particulars from the Hon. Secretary, A. Beeston, 103, Nottingham Road, Nottingham.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, March 7 to 12:—

APPARATUS.—No. 7,646. Machines for sensitising papers, etc. B. J. Hall.

APPARATUS.—No. 7,647. Apparatus for continuous washing and drying of blue-prints, etc. B. J. Hall.

DYE PROCESS.—No. 7,788. Process for treating and dyeing photographic images and products obtained thereby. W. van D. Kelley.

LANTERN PROJECTION.—No. 7,450. Passing picture slides through magic lanterns, etc. A. E. Orr.

APPARATUS.—No. 7,538. Light-condensing device. K. de Proszynski.

CAMERAS.—No. 7,656. Bellows camera. E. J. Sark.

PRINTING.—No. 7,578. Printing machine. Chromatic Film Printers, Ltd., and L. J. Hibbert.

COLOUR PHOTOGRAPHY.—No. 7,579. Production of printing surface for making coloured screen-plates, films, etc. Chromatic Film Printers, Ltd., and L. J. Hibbert.

CINEMATOGRAPHY.—No. 7,273. Composition for treating cinematograph screens, etc. J. W. Byford.

CINEMATOGRAPHY.—No. 7,757. Cinematograph projection shutter. J. Crawley and W. Harris.

CINEMATOGRAPHY.—No. 7,295. Cinematographic apparatus. D. Kennedy.

COLOUR PHOTOGRAPHY.—No. 7,517. Direct-colour photography and/or cinematography. M. Martinez.

PHOTOGRAPHIC SUPPORTS.—No. 7,518. Double-faced photo, etc., recording supports. M. Martinez.

COLOUR PHOTOGRAPHY.—No. 7,519. Double-faced supports for direct-colour photography or/and cinematography. M. Martinez.

STEREOSCOPY.—No. 7,520. Stereoscopic and/or colour cinematography. M. Martinez.

CINEMATOGRAPHY.—No. 7,521. Multiple printers for cinematography. M. Martinez.

COLOUR CINEMATOGRAPHY.—No. 7,522. Colour cinematography by interference of rays. M. Martinez.

COLOUR PHOTOGRAPHY.—No. 7,523. Screens for colour cinematography. M. Martinez.

COLOUR PROCESS.—No. 7,524. Process for stereoscopic or/and colour cinematography. M. Martinez.

CINEMATOGRAPHY.—No. 7,863. Cinematograph, etc., projection screen. R. Wellesley.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

AERIAL CAMERAS. No. 134,851. (June 5, 1915.)—The method of taking photographic pictures of country from aircraft comprises moving intermittently a narrow strip of sensitive film in a direction transverse to the direction of flight, exposing such an amount of this film after each movement that the size of the exposure measured lengthwise of the film is a multiple of the size of the exposure measured across the width of the film, the several exposures on the film being then individually separated and suitably pasted one over the other by their longitudinal edges to form a complete panoramic or composite picture.

Fig. 1 shows a single picture, the elongation a of which transversely to the direction of flight is approximately four

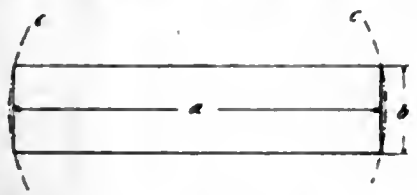

Fig. 1.

times as long as the dimension b in the direction of flight. The circular lines c denote the circle cast by the objective.

Figs. 2 and 3 show in front view and transverse section an example for the juxtaposition of the pictures. The film band is so shifted onwards transversely to the direction of flight that the picture taken at the moment in the direction of flight has as small an elongation as possible in this direction and therefore on the other hand as great an elongation as possible transversely to the direction of flight. The separate copied strips of picture a^1 which result after the subdivision of the film band are laid over each other at their longitudinal edges like the tiles on a roof so that a continuous finished panoramic picture results.

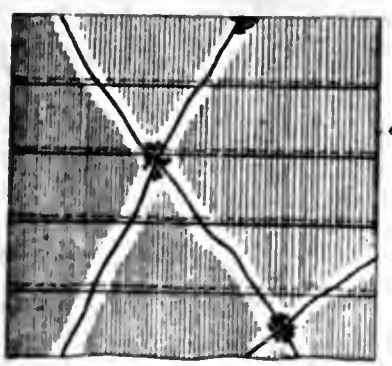

Fig. 2.

Fig. 3.

To the part d of the casing carrying the objective c is attached the casing d^1, in which are placed the means for guiding and feeding forward the film h. This film h runs from the roller g from which it is unwound to the roller g^1 on to which it is wound and is exposed by the well-known roller-blind shutter f consisting of a band with a longitudinal slit f^1 in it. The intermittent feeding forward of the film is effected by known means independently of the operation of the roller-blind shutter f, in such a way that every time the film h comes to rest the exposure slit f^1 is moved past transversely to the longitudinal direction of the film. For this purpose the following arrangement which is shown by way of example serves:

The film h is directed between a pressure roller m with a peripheral recess m^1 in it and a roller n which latter is connected by a friction cord o or the like with the core p of the roller on to which the film is wound. This roller n co-operates by friction with the roller m, but when the roller n ceases to remain in driving engagement with the roller m when passing over the recess m^1 the roller m will slip past the film which in consequence will remain stationary until the roller n again engages with the periphery of the roller m.

The intermittent feeding forward of the film produced thereby

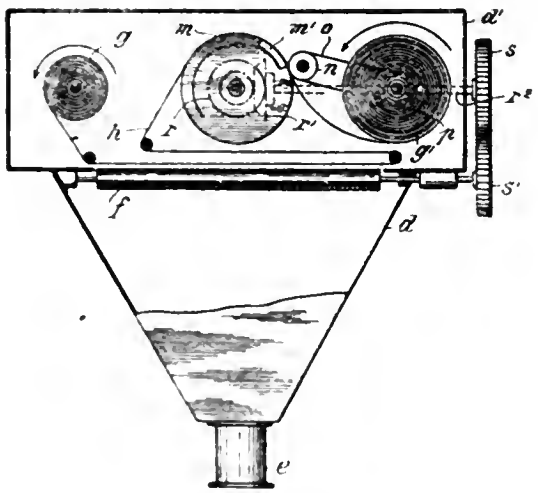

Fig. 4.

produces also the intermittent forward movement of the winding up arrangement.

The axle of the feed roller m is connected by a bevel wheel r to the bevel wheel r^1 on a spindle r^2, which has mounted on its other end a gear wheel s, which as shown in fig. 6 has teeth on only a portion of its periphery and which gear wheel gears into the gear wheel s' on the spindle t of one of the rollers for the shutter. Consequently when the feed roller m rotates the gear wheel s^1 is also set in rotation by the gear wheel s and again released whereby as the spindle t^1 of the other roller for the shutter is controlled by a spring u which is set when the shutter moves forward, the shutter is released so that it flies back and during this backward movement the slit f^1 moves over the stationary section of the film transversely to the longitudinal direction thereof and so exposes it. The instant of the co-operation of the recess m^1 with the feed roller m therefore coincides with the instant of the release of the gear wheel s^1 by the part of the gear wheel s which has no teeth, so that

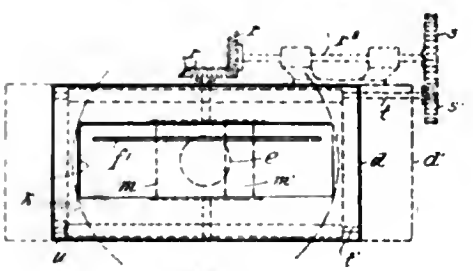

Fig. 5.

Fig. 6.

therefore the requirement that the exposure shall take place while the film is stationary is fulfilled.

It is obvious, of course, that the slit f^1 must be inoperative when the roller-blind shutter is being reset (*i.e.*, when the gear wheel s^1 co-operates with the part of the wheel s which has teeth and when the film is moving), and this can be ensured in the well-known way by covering over the slit during the resetting of the shutter by means of a slide or the like, the slide exposing the slit again when the shutter flies back. An example of this arrangement is shown in fig. 7 in which f denotes the roller-blind shutter, f^1 the exposure slit therein and t, t^1 the spindles of the rollers for the shutter. As previously

stated. the spindle t^1 is controlled by a spring u, which tends to wind the shutter f on to the roller mounted on the spindle t^1. Under the shutter f lies the slide v which is guided in lateral guides v^1 and is connected at one end to a spring w attached to a fixture w^1, which spring constantly tends to draw the slide towards the stop y^1. The other end of the slide v is provided with a recess in which a hook x, pivotted to the shutter f, is adapted to engage. Assuming the slide v to be against its stop y^1 and the shutter is being rewound during an exposure on the roller on the spindle t^1, it will be seen that when the hook engages with the edge of the slide v it will ride over this edge as it has a curved or cam-shaped contour, and engage in the recess in the slide. Thus when the shutter is moved in the opposite direction on to the roller mounted on the spindle

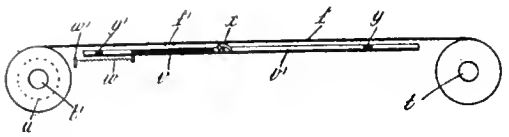

Fig. 7.

t the slide will be moved with it and will thus cover the exposure slit f^1 and render the latter inoperative. Of course the slide will be sufficiently close to the shutter to prevent light reaching and fogging the film when the latter is being moved. Now when the shutter has been moved the required distance towards the roller on the spindle t the nose of the hook x will engage with a fixed stop y, will be depressed thereby and the hook will be released from the recess in the slide which will thus fly back to the stop y^1 under the action of its spring w. Thus the slit will no longer be covered so that light may pass to the film. The operation of the parts are so timed that the slide flies back just before the teeth on the gear wheel s move out of engagement with those on the gear wheel s^1 so that the release of the slide is ensured.—Oskar Eduard Messter, 110-111, Leipziger Strasse, Berlin, W.8.

The following complete specifications are open to public inspection before acceptance :—

CINEMATOGRAPHY.—No. 159,851. Cinematographic projecting screens. J. Emlington-Darling.

COPYING DEVICE.—No. 159,828. Device for copying the surface to be obtained from a photo-stereogram of a spatial form. C. Zeiss.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

IMPEX.—No. 411,020.—Photographic plates and photographic films. The Imperial Dry Plate Co., Ltd., Ashford Road, Cricklewood, London, N.W.2., manufacturers of photographic materials. December 29, 1920.

IMPEX.—No. 411,021. Photographic sensitised paper. The Imperial Dry Plate Co., Ltd., Ashford Road, Cricklewood, London, N.W.2. December 29, 1920.

DESENSITOL.—No. 411,785. Chemical substances used in photography, photographic plates and photographic films. Ilford, Ltd., Britannia Works, Roden Street, Ilford, Essex, manufacturers of photographic plates, paper and films. January 22, 1921.

DISTAR.—No. 362,971. Optical instruments. Carl Zeiss, 2, Carl Zeiss Strasse, Jena, Germany, manufacturers of optical and philosophical instruments. August 1, 1914.

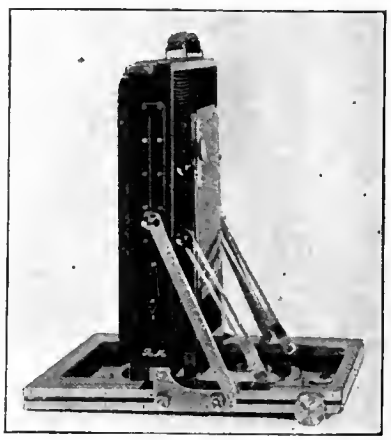
PROXAR.—No. 362,972. Optical instruments. Carl Zeiss, 2, Carl Zeiss Strasse, Jena, Germany, manufacturers of optical and philosophical instruments. August 1. 1914.

New Apparatus.

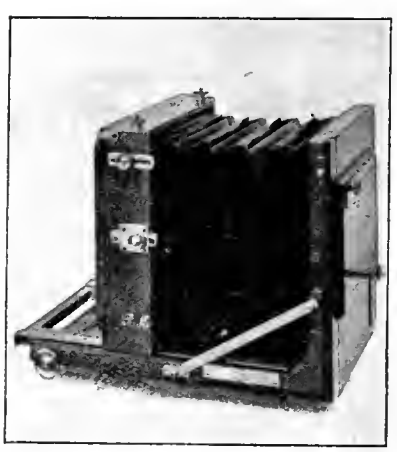
R.M. Field Cameras. Sold by the London Camera Exchange 2, Poultry, Cheapside, London, E.C.2,

Two models of field cameras, supplied as their specialties by the London Camera Exchange (Robbins, Manistre & Co.), have been sent to us for our examination. One is a light model with taper bellows; the other, of heavier square-pattern build. Both are of exceedingly good design and workmanship, and both can be obtained in teak instead of mahogany for 5 per cent. extra on the prices given below.

The light model is of double extension, 19 inches in the whole-plate size, and has a thickness of 2½ inches when folded. One special feature of it is the wide-angle movement, which is obtained by providing on the baseboard a second pair of supports for the



lens front. This allows of lenses of the shortest focus which could be usefully employed being made available. The camera is very well provided with rising front. The front as a whole can be raised inches, and a further rise of about 2 inches is obtainable by raising the lens panel, which is of ample dimensions, 7 × 3½ inches, for this purpose and for taking large lenses. The panel movement also allows of good rise when a wide-angle lens is being used. There is both front and back swing, and the brass fittings are of specially substantial make, brass binding and plates being fitted in places where there is a tendency to wear. The camera is made



with a solid baseboard, but can be supplied with turntable and tripod for a further £4. Altogether it is a high-class instrument, light yet strong. Including three double book-form plate-holders, the price in half-plate size is £13 10s.; in whole-plate, £17 10s.; in 10 × 8, £22 10s.; and in 12 × 10, £27.

In the square bellows pattern the extension in half-plate size is 19½ inches, and the rise of front 2 inches. Three is ample swing back, and also side-swing movement on the brass runners. In this

model also special commendation must be given to the solid construction of the brass and metal work. The camera is a first-rate pattern of the rear-focussing type, such as is favoured by many photographers. It is a camera able to stand much hard work in the field, and one which serves also for studio use. The prices are the same as those for the light model. In each model, brass-binding throughout of camera and plate-holders is obtainable at prices running from £2 15s. to £4.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MARCH 28.

Croydon Camera Club. Easter Monday Outing.
North Middlesex Phot. Soc. Outing to Rickmansworth.
South London Phot. Soc. Portfolio Exhibition.

TUESDAY, MARCH 29.

Bournemouth Camera Club. A.P. and P. 1920 Prize Lantern Slides.
Bowes Park and District Phot. Soc. Informal Meeting.
Leith Amateur Phot. Assoc. Annual Business Meeting.
Portsmouth Camera Club. "Photographic Dodges." Eng.-Cmdr. Mowlam and Others.

FRIDAY, APRIL 1.

R.P.S. Pictorial Group. "Control in Printing." N. E. Lubosher.

CROYDON CAMERA CLUB.

Mr. C. P. Crowther kindly filled a gap in the syllabus with a lecture entitled "Psychology in the Studio," and succeeded in highly interesting all.

Psychology, he said, might be deemed to be the application of experience and talent developed by years of study till the act itself was done unconsciously or subconsciously. In the studio it was compulsory to converse with sitters until they arrived at the unconscious mood. Only in such way could characteristic portraits be obtained, though no concrete directions were possible to teach a method of catching the evasive characteristics of sitters.

A capital set of slides illustrating varied professional portraiture was shown. A slide by Mr. Herbert Lambert, of Bath, well showed the pleasing diffused definition afforded by one of the old landscape lenses at a large aperture. He employs a star-shaped stop in lieu of the usual type, as affording a more pleasant quality of image. Mr. Crowther said he could offer no opinion on this, but on raising the question at the R.P.S. he had been informed that the star-shape could make no possible difference.

Granted this be true for a corrected lens free from zones, it is by no means apparent that the same remark applies to a single achromatic lens at large aperture. With the latter at *f*/8, owing to outstanding spherical aberration, focussing is so difficult that it is the usual plan to focus with smaller diaphragm and then open out. Now, if we assume a fairly small central stop good definition is secured. Next, if we enlarge this aperture by radiating V cuts, then the "quality" of the image, compared with that furnished by a circular stop of equal area, may well be of perceptibly different character, as, so to speak, the aberrations are being drawn upon in different ratios. It is quite an interesting point, and it only remains to suggest to those who may care to make comparative tests, and are not optically inclined, that the *f* value of the irregularly shaped stop may be approximately ascertained by laying it, and one of the Waterhouse regular stops (or if iris, a cut-out equivalent circle) on small squared paper, and counting the squares in each case. Exposures will be in direct ratio.

In justice to Mr. Crowther it should be said that the foregoing is but an imperfect summary of some of the points raised. The lecture was keyed in highly strung vein, and delivered from an altitude. His main contention, so far as could be gathered, was that all great achievements in art were secured sub-consciously and without much effort. On this a hot discussion arose, to which space does not permit reference; possibly little real difference of opinion existed due to misconception of definitions.

Mr. Salt, who opened the discussion, found himself in complete and cordial disagreement with the main thesis. Mr. Cavendish Morton, after pointing out to the last speaker that those who split hairs frequently were bald, cut the mundane, climbed on to the roof after the lecturer, and then held forth from the top of the flagstaff. And Mr. Crowther looked up and blessed him.

"What are we?" dramatically inquired Mr. Cavendish Morton, and supplied the answer by saying—"The products of bodies and souls wounded in countless generations." ("I suspected as much," here interjected the "office boy.") "The artist," he added, "is to be distinguished by his hyper-sense to the subtle things of life, and his art is the sacrament made to powers of good or evil." This is a mere sample from bulk, but sufficiently indicates the transcendental atmosphere kicking about. Mr. King brought all to earth with the proverbial charwoman's bump by saying that he found children, owing to their absence of self-consciousness, much easier to photograph than adults. Those accustomed to public speaking (adults), such as the clergy, actors, and bookmakers, made the best sitters. Mr. Ackroyd remembered as a child, some seventy or eighty years ago, being given some toys to play with by a photographer, mistaken for presents with eventual heart-burning. Mr. Reynolds was curious to know how the sub-conscious theory applied to scientific work.

Mr. Sellors regarded the theory as dangerous, as a lot of sub-conscious badness might be stored. Mr. Harpur regarded himself as one of the sub-conscious sort; all his finest work had been done that way. Mr. Purkis made some remarks on supplementing common sense and "following your nose"—excellent advice provided the nose is not bent sideways. Mr. Crowther, in a general reply, said he was glad to think that for once the reporter would be compelled to record that sentiment reigned over and held the members of the Croydon Club. It can be recorded with more accuracy that all thoroughly enjoyed a first-class evening, and will look forward with pleasure to hearing the lecturer again.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held on March 11 at 35, Russell Square, when there were present Messrs. Marcus Adams, A. B. Basil, Frank Brown, W. B. Chaplin, A. H. Chapman, G. Chase, Alex. Corbett, T. Chidley, Alfred Ellis, R. Haines, G. Hana, W. Illingworth, H. St. George, R. N. Speaight, F. G. Wakefield, H. Wheeler, W. H. Wedlake, and the Secretary, Mr. Lang Sims.

Letters regretting absence were read from Messrs. Dickinson, Fry, Gray, Lambert, Read, Spink, Turner, and Swan Watson.

The finance committee reported that they had met that day, and recommended for payment various accounts.

Mr. Speaight reported that at the last meeting of the Congress committee it was decided to recommend the Council that each business meeting in Congress week should have its individual Chairman, and that certain guests should be invited to the dinner. These recommendations were approved.

There was some discussion with regard to the date of the annual meeting, the room in which it was to be held being required for the afternoon of Wednesday, April 20. It was agreed that the meeting take place at 2.30 p.m. on the following Friday.

The Secretary reported that the Autotype Company had offered to give a "Carbro" demonstration at the Congress, and it was agreed that the Secretary should reply that the only convenient time would be 2.30 p.m. on the Tuesday.

Mr. Crowther had written saying he would be glad to use a lantern, and he could then show examples of work by several prominent photographers. The Secretary was asked to inform Mr. Crowther that a lantern would be available.

Mr. Marcus Adams reported with regard to the Exhibition that everything was going on satisfactorily.

The Secretary reported that there was a brisk demand for Congress badges, and hoped members would follow the good example set so that the official list might be complete when printed.

The Secretary presented an unusually long list of new members, totalling 33. All were elected.

A number of interesting letters were read by the Secretary, all

having reference to matters in which members sought the advice of the Council. The replies suggested by the Secretary were confirmed, and the Council rose after a sitting of nearly three hours.

COUNCIL AT DINNER.

In the evening the members of the Council dined together at Gatti's, in the Adelaide Gallery. Mr. Frank Brown (President) genially presided, and the evening was most happily spent. Reference was made to the growth of the Association, and several lines along which development and increasing usefulness was looked for were indicated.

The health of the President was heartily drunk, as was also that of the President-Elect.

News and Notes.

TO APPRECIATE FINE ART.—A mind trained to the understanding of fine art is plainly a vital qualification of those who aspire to produce works by photography claiming to be "art," whether portraiture or landscape. Yet how seldom is that qualification found. The obstacles in the way of acquiring it are certainly great, for many have not the opportunity of attending an art school, and, after all, the average school of art is simply an institution for teaching people to draw. Therefore, it is with a good deal of pleasure that we see that Mr. F. C. Tilney has established a postal course of training in this subject as a natural issue from a general course (The Art of Life), in which the student is led to train himself in the principles of æsthetics. This latter course, as we know, has been widely appreciated, and we are sure that in seeking to guide those more particularly interested in fine art Mr. Tilney is ministering to a widely-felt need. Particulars of the course are obtainable from him at 28, John Street, Bedford Row, London, W.C.1.

HULL PHOTOGRAPHIC SOCIETY.—Once again the Hull Society has its exhibition housed in the City Art Gallery, where it has been opened by Alderman J. Pybus, the Chairman of the Art Gallery Committee and a member of the Hull Society since its inception 37 years ago. There are nearly 200 prints on view, including nearly a score of prints by Mr. Marcus Adams, of London, and Mr. John M. Whitehead, of Alva. It is satisfactory to learn that the show was a bigger and better one than last year's, which provides an interesting sidelight on the stimulus resulting from last year's publicity. There are certain disadvantages attendant on such a method, such as a financial loss, but there is no objection to the prints remaining hung until May, and they can be viewed under almost ideal conditions. The Hull gallery is one of the prettiest and best-lighted galleries in the country. The president, Mr. L. Kirk, shows some interesting multi-colour Bromoils of fine artistic taste and delicate colouring. The technique of J. W. Atkinson is very praiseworthy, and C. Oxtoby's architectural examples form a notable group. Variety of subject is very noticeable in the work of Cyril W. Rodmell, and outstanding exhibits are also shown by J. T. Dyson. W. Dalton, C. A. Manning, G. R. Langdale, R. Proudlove, and H. C. Stephenson. There is one lady exhibitor—Mrs. Rivers Freeling.

Correspondence.

STEREOSCOPIC RELIEF.

To the Editors.

Gentlemen,—I see from your "Paris Notes" in the "B.J." of March 11 that another interesting attempt has been made to give stereoscopic effects on the screen—with one picture, I suppose; otherwise there would be nothing very striking about the claim. Your patents columns from time to time give abridged specifications of similar inventions, some of which are hardly convincing, and others quite absurd. The phrase "stereoscopic relief" is often used quite wrongly, and by no one more than photographers, who ought to know better. A good lantern slide with a strong foreground is almost certain to evoke the praise, "My word! That's quite stereoscopic." And photographers will sometimes insist that by closing one eye and looking with the other through the tunnelled fingers they can see stereoscopically.

I am inclined to think that quite a fair number of people never have seen a slide properly in the stereoscope, and that this may account for the lax use of the term. Amongst my own small circle there are two who cannot see a slide properly—one man I found out quite accidentally. He was passing slides through the stereoscope with the usual "very nice," "very good," and at the finish I said, "Now look at this," and replaced the last slide by the same view with R. and L. halves transposed. It was a view through foreground foliage, but he saw—and even when told what to look for, could see—no difference.

I think there may be many people who, when looking through the stereoscope, or when looking at any very close up object, unconsciously throw one eye out of action. A sailor or microscopist does this at will when using a telescope, though he would probably describe the action as quite unconscious.

In your issue of November 26, Dr. F. W. Edridge-Green is reported as saying that a foreshortened revolver in a picture gives a striking stereoscopic effect, and he goes on to say that the perception of binocular relief is independent of double images. It doesn't sound very convincing. Apparently a man who has lost the sight of one eye may still see stereoscopically if the artist will only paint a revolver as seen from two sides at once.

I may have misunderstood Dr. Edridge-Green's experiment with a stereo-slide, but I enclose three slides, one ordinary, one cut through the distant point of sight, and one cut through a convenient foreground object. But, like the Paris spectators, I quite fail to see the slightest stereoscopic effect in the two slides so treated. And if dissimilar views for each eye are not essential I have wasted some "cursory breath" when I have bought Continental stereo-slides, and on getting home have found that the R. and L. halves were exact duplicates.

Last week you have an article on the "Photographic Method of Detecting Changes in a Complicated Group of Objects," the mathematics of which to an ordinary photographer are simply appalling. There are no less than 18 factors, and after a hearty feed on these—one is tempted to call it an indecent debauch—Mr. Stillman tops up with logarithms and graphs as a sort of liqueur. But I am afraid that by the time Mr. Stillman gets to the liqueurs the rest of us are already under the table.

Given the two pictures illustrated, all that is necessary is to mount them as a stereo-slide. The stereoscope will reveal quite clearly any changes in the heap.

THE NEGATIVE AND THE PRINTING PROCESS.

To the Editors.

Gentlemen,—It is always a pleasure to me to find that your correspondents have taken an interest in anything that I have written—even when the interest shows itself in criticism. May I be permitted to reply to that portion of Dr. B. T. J. Glover's letter in your issue of to-day, that has reference to my article on non-bromide printing processes?

Dr. Glover is perfectly correct in stating that "prints from the same negative upon different papers" cannot be usefully compared, This is a point I insisted on when writing to you on the subject of factorial development in your issue of February 25, advising different factors for negatives to be used for different papers. What I should have made clear, but evidently did not, was that when writing of the comparison of prints from the same negative, but on different papers, I was assuming the gradation remained constant in each case. One can obtain bromide paper with as soft a scale as carbon. This I think I made plain later in the same article when writing:—"It is frequently claimed on behalf of bromide papers that they are indistinguishable from carbon or platinum; this is claiming too much, because, although their range of contrast and gradation may be identical, their physical construction. . . makes just that difference-in quality in the print."

I should not trouble you to correct my statement, which, as it stood, was obviously incomplete, but for the fear that, maybe, some of your readers would imagine that if they could get perfect grada-

tion on bromide paper, their prints were necessarily of perfect quality. This is not so: Contrast and gradation being equal, a carbon or platinum print has a quality, richness, depth, call it what you will, that no silver-in-gelatine image can for one moment be compared with.

In common, I am sure, with many more of your readers, I am looking forward with great interest to Dr. Glover's promised article. The more clearly and fully factorial development is expounded in your columns the better for photography, and for photographers.

In conclusion, I wonder if "Old Printer," who is evidently not particularly satisfied with present-day assistants' posts, has ever thought of trying one of the photo-mechanical printing processes that depend on the same basis as "carbon," as a means to earn a living! I know that at one time carbon printers were welcomed by many collotype houses, and I believe there are still openings to be found in this branch.—Yours faithfully,

ARTHUR C. WILLIS.

March 18.

THE PROFESSIONAL'S DEVELOPER.

To the Editors.

Gentlemen,—As soon as I saw Mr. Jones's article about his developer I decided to try it, but as two gallons is rather a large quantity to make up for an experiment, I reduced it about ten times and made it up as follows:—

Metol	3 drams.
Hydroquinone	6 drams.
Soda sulphite	3 ozs.
Caustic soda	1½ ozs
Water	32 ozs

It worked remarkably well when diluted to 1 oz. to 15 of water, but 2½ minutes is rather a short time for development when developing flat films, as one would bromide prints; and after a trial, as he suggests, I diluted to 25 ozs. of water and gave four or five minutes' development, with very good results. The stock solution soon showed signs of discoloration, even when kept in a stoppered bottle, but this did not seem to affect the result at all, and the caustic soda made my fingers rather like a washerwoman's, and decidedly tender. Then a week later came Mr. Jones's correction and Mr. Ermen's letter suggesting a reduction in the amount of caustic soda, so I made up another 32-oz. bottle, but with even less soda than Mr. Ermen suggested, and now it stands thus:—

Metol	3 drams.
Hydroquinone	6 drams.
Soda sulphite	6 ozs.
Soda caustic	½ oz.
Water	32 ozs.

It is now an excellent developer. Diluted to 1 oz. made up to 25 with water it gives an excellent portrait negative in five minutes. The reduction in soda makes it less objectionable to the fingers and generally improves its quality as a developer.

When developing films like bromide prints the fingers are constantly in the solution, far more so than when handling plates, so that the reduction in the amount of caustic removes the only objection I could urge against it.

The increase in the amount of sulphite is also a great improvement, as the solution remained practically colourless when kept for several days in an unstoppered bottle, and the developer after use remains quite clear even after it had been used for some time. I found when over-exposure was suspected that a few drops of bromide solution were useful. I feel sure that this developer allows a shorter exposure to be given than when using pyro-soda, but I believe the chemists tell us that all developers are alike in the final result if we only carry them to the stage when all the silver bromide in the gelatine film affected by light has been reduced by the developer. But that is just what the man who takes photographs never does, so that we are quite satisfied that we can make a difference in the final result by using a different developer, and I believe the "Professional's Developer" enables me to reduce exposure, especially in portraits, very considerably, and I am grateful to Mr. Jones for publishing his formula.—Yours, faithfully,

HALF-WATT.

PRESERVING PYRO.

To the Editors.

Gentlemen,—Those who use pyrogallol in small quantities at fairly long intervals often find that the stock solution, made with sulphite and metabisulphite, deteriorates rather rapidly. In such circumstances it is preferable to revert to the old plan of using sulphuric acid as the preservative. If three drops of pure sulphuric acid are added to five ounces of water, and one ounce of pyro dissolved therein, the solution will remain unchanged for a prolonged period. If distilled water be available it should be used, otherwise tap water which has been boiled for fifteen minutes to expel any air will answer well. The sulphite necessary to prevent staining the film may be added to the soda solution. If this be done no advantage is gained by adding metabisulphite, as the free sulphurous acid to which it owes its efficacy is immediately neutralised. It is not perhaps generally known that a concentrated one-solution pyro developer will keep for months if bottled in small vials or tubes which are filled nearly to the cork and well sealed. I have used such a developer twelve months after bottling, and found it as active as if freshly mixed.—Yours faithfully,

PYRO-SODA.

DARK BACKGROUNDS.

To the Editors.

Gentlemen,—The Ex-Cathedra note on dark backgrounds has evidently aroused a great deal of interest, and it is quite evident that it deals with a problem in which we are all interested. I am afraid I do not agree with Mr. Godfrey Wilson's suggestion to pose the sitter so close to the background as to cast a shadow up on it to give some gradation to the tone of the background. I think that when a dark background is used it is best to keep the sitter as far from it as possible, in order to give the effect of space between the background and sitter. In fact, I often place the sitter in the middle of the studio and use one end of the room, which is rather dark, with dark curtains and dark old furniture as a background. It is, of course, very much out of focus, and generally "without form and void" in the print, but with considerable variations of tone (using the word *tone* in its strict pictorial sense, which has no reference to colour).

By moving the camera it is possible to get the darkest part of the background against the light side of the figure; or if movement of the camera will not produce the right effect, a piece of furniture, such as a dark settle, can be moved until the desired result can be obtained. By this arrangement perspective is produced in the background, which gives relief to the figure and prevents the objectionable effect of the figure having been cut out and pasted upon a piece of black paper. I think the background should never be as dark as the darkest shadows in the figure, and also with light backgrounds the highest light in the figure should be lighter than any part of the background; and even in sketches (which, as a rule, have no claims to artistic effect) the background just round the figure should be darker, if only in the slightest degree, than the highest lights of the figure.

Some photographers go to the expense of constructing a cave lined with black velvet and pose the sitter in front of it, in order to make the figure stand out from the background, but this is just what it doesn't do; it produces the cut out and pasted on effect I have already referred to. When managing a studio in London I had many arguments on this point with the business managers, but, of course, I failed to convince them, and a velvet cave was constructed at great cost, and was a failure, as I knew it would be. And they also had pictorial (so-called) backgrounds painted with everything as hard and sharp as the edge of a knife, with the same result, the figure looked pasted on the background, and when I showed them sitters taken in front of a real Seavey background, in which everything was soft and broad, and the figures stood out from it in a delightful way, they weren't convinced. They tried to corner me once by bringing a beautiful print of an old man's head against a dark background, from which it stood out in fine relief, and they argued that the background was quite black, and so my contentions were wrong, but I was able to point out that the velvet collar on the old man's coat was blacker than anything in the background, but again they weren't convinced. So we each stuck to our own opinion.

When working up enlargements in which the background is dark I can lift the figure away from the background best by emphasing the shadows in the figure, especially the dark shadows in the hair, until they are darker than most of the background.—Yours faithfully, CAMEO.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

G. J. H.—We have now ascertained from Paris that the "Radius" projection lamp is constructed and sold by M. de St. Genest, 61, Faubourg Poissonnière, Paris.

S. W.—(1) This is ordinary water-colour mixed with gum, as used for finishing glossy prints. (2) A lens of 3 inches focal length would undoubtedly give more depth than one of larger size, even when the prints were enlarged, but whether the quality for Press purposes would be equal to that of direct 5 × 4 negatives it is difficult to say without an actual test.

H. N.—Theoretically a suitable light-filter is necessary, and so it is in practice if the results are to be comparable with those obtained with a filter adjusted to the plate for use in daylight. While this is so, you will certainly get a pronounced advantage from the use of the panchromatic plates with flashlight, and probably, dependent on the subject, it may not be worth while to use even a K 1 screen.

H. P. E.—(1) So far as we know there are not any restrictions on photography in Holland beyond those which apply to picture galleries and such places, where conditions are similar to those here. (2) We think there is certainly no duty where a camera accompanies the traveller as personal luggage. (3) Similarly, such a supply of roll-film as would serve for a holiday would, we think, be passed in.

S. E.—We are not lawyers, and your question is solely one of common law, but our opinion is that X. is solely liable for payment of the account. The admissions which he appears to have made to you further confirm this view, and so do the statements of the club, which we should say would not be upset in County Court proceedings, since the club appears to have advertised to the same effect. Therefore it seems that you must find X., and issue a writ for payment.

G. G.—We cannot trace a developer specially suitable for wedding groups having been recommended in our pages, and do not think there is any formula substantially better than another for this purpose, except that the developer should not be of full strength, otherwise it is liable to give too great a density of deposit in the highlights of the subject. We advise you to use ordinary pure soda diluted with an equal bulk of water, and a fairly rapid portrait plate, which is made specially for a long series of gradations.

R. M.—(1) A private company, not incorporated under the Limited Liability Act, and trading under a name other than that of its partners, requires to be registered with the Registrar of Business Names, 39, Russell Square, London, W.C.1, and to comply with the regulations of the Registration of Business Names Act. (2) Under the 1911 Copyright Act there is no further formality. The written assignment of the copyright to your firm by the artist who makes the painting to your order establishes your ownership of the copyright.

A. B.—Full descriptions of Daguerreotype are to be found only in older text-books, and particularly those published between the years 1845 and about 1860. All of them, of course, are now long out of print. The Patent Office Library has a very good collection of these early manuals, and we think your best course would be to look up those which you think would be of service to you, and then, no doubt, you could buy one or other of them from Messrs. Sotheran, 140, Strand, W.C.2, whose large catalogue, issued a few weeks ago, contains quite a number of these treatises on the early photographic processes.

G. B.—There is very little choice in studio gas lamps. One is the "Howellite," of Griffins; the other is, or was, obtainable from the Kodak Co., under the name of the "Powerful." But both these lamps give out a great deal of heat, and for a small studio like yours, unless it is very well ventilated, the heat might easily be excessive. As regards the focal length which you can use, you do not mention the size of plate, so the best we can do is to refer you to the table in the current "Almanac," from which perhaps you will be able to see the focal length of lens which you can manage to use, but in so short a run as 12 ft. you cannot use as long a focal length as you should.

J. A.—We suppose your groups are liable to extend across the full width of the studio, namely, 12 ft., or pretty nearly as much as that, in which case, in order to include the whole group on a post-card, your lens, in a 16-ft. studio, ought not really to be more than about 4½ inches focus—that is, allowing 3-ft. run for placing the group and 3 ft. for the space behind the lens. We dare say you could do with a less distance than this, and perhaps your groups also are not as wide as 12 ft., but at the outside we should say you cannot have a lens of more than 6 inches focal length. For covering a postcard sharp to the edges, you ought to be able to get an anastigmat of about *f*/6 aperture, or *f*/6.8, and of this focal length, but we should certainly advise you to have the lens on trial, and find out by actual tests in the studio whether the 6-inch focus actually enables you to include as large a group as you require on the plate.

T. T.—You appear to have an ordinary Thornton-Pickard roller-blind shutter, of which you can get working particulars from the Thornton-Pickard Co., Altrincham, Cheshire. The graduated toothed disc is a tension disc, which you wind until the required speed marked on it comes opposite to a given mark. It works by increasing the tension of the spring, and so the speed of movement of the flexible blind. The part marked I.T.B. requires to be shifted according as you wish, to give quick exposures on single pressure of the bulb, or exposures as long as you keep the bulb pressed, or exposures by pressing the bulb for opening and again for closing. It would take too long to explain how to test a camera and lenses. You need to get one of the text-books on photography, for example, "Photographic Lenses," by Andrews and Beck, sold by R. and J. Beck, Ltd., 68, Cornhill, London, E.C.3. The Beck "Symmetrical" is a good lens of the R.R. type, and ought to give satisfactory negatives over a moderate angle, say that of 5½ inches focus on a quarter-plate.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3178. Vol. LXVIII. FRIDAY, APRIL 1, 1921. Price Fourpence.

Contents.

SUMMARY

Mr. F. E. Ives has applied his dye-mordanting process to the colour-toning of transparencies on glass or celluloid (P. 186), and had also recommended a special form of the process for the intensification of negatives. (P. 187.)

Mr. C. Brangwin Barnes, in a contributed article, gives a formula for making glazing solution, and deals at length with the several precautions which are necessary in the successful glazing of prints by stripping from glass. (P. 185.)

Dr. B. T. J. Glover, in the first portion of a paper on the comparison of development methods, offers a very lucid exposition of the relation which a negative requires to have to the subject on one hand and to the printing paper on the other. He touches upon the difficulty of fulfilling the latter condition by watching the progress of development. In the next instalment of his paper he will deal with factorial and time development from this standpoint. (P. 183.)

Mr. Frederick H. Evans urges the anti-halation merits of double coated plates, and adds a note on the making of negatives for platinotype printing. (P. 190.)

The programme of the Congress to be held by the Photographic Dealers' Association during the period of the forthcoming Fair will be found on page 187.

Mr. Elwin Neame is to lecture in London on photography in advertising, on Monday next. (P. 190.)

A correspondent, while admitting the possibilities of producing fine work in a studio with a south light, gives a recital of the practical inconveniences which are inevitable in regular practice. (P. 190.)

The feminine foible of disliking a dress or a hat or a portrait which bears a close resemblance to somebody else's is a factor in the arrangement of the show windows which the photographer cannot afford to overlook. (P. 181.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT

Dr. E. König has given particulars of a new colour-sensitising dye having pronounced action in the green region of the spectrum, and thus facilitating processes of colour photography and colour cinematography. (P. 16.)

Mr. F. E. Ives announces a stereo-colour outfit specially designed for medical records. (P. 16.)

Full working details of the method of making colour transparencies by assemblage of three colour images have recently been given by two American workers, and serve to keep alive a process which is in danger of being forgotten. (P. 13.)

EX CATHEDRA.

Halation and Development. Referring to the correspondence upon this subject, an old practitioner writes that most outdoor workers have found out that the minimum of halation occurs when the period of development is short. He says that in the early days of gelatine plates when "tentative" development was practised, halation was a real bugbear, but that when plates which would stand quick development came upon the market, the trouble was lessened. It is certainly reasonable to assume that provided a developer is energetic enough to produce the necessary density before it has had time to penetrate right through the film, the smaller the chance of developing any light-action which has taken place next the glass. We have not had the opportunity of putting this to the test of using a weak developing solution in a tank. According to this theory the maximum of halation should be produced in this way. We can, however, confirm our correspondent's statement, that rapid development is the best method to follow. Some few years ago a good deal of prominence was given to an American developing formula which was, if we remember rightly, simply one which gave full density very quickly. It is very necessary, however, to distinguish between local over-exposure and halation, by which is understood the spreading of light-action by reflection from the inner surface of the glass plate.

* * *

Repetition. Anyone acquainted with the process of reasoning in the feminine mind will be aware of the fact that many ladies will absolutely refuse to wear a particular pattern of material or "mode," no matter how well they may realise its suitability, if someone of their acquaintance possesses an identical thing. This fact, however, seems to be ignored by many photographers, when exhibiting specimens of their work, for time and again in windows, and show cases, do we see a repetition of some particular style of posing, and lighting, with several different sitters, which shows a lack of knowledge of this trait of the feminine character. Recently, we noticed a particular chair depicted in no less than five portraits in a country photographer's window. This points to the fact that the photographer had little originality or mental perception, or he would have made an endeavour to arrange something slightly different in the matter of pose, lighting, and accessories for each of the five distinct sitters, while if a certain treatment was so good as to bear repetition, then it was a mistake to show more than one example of it at a time. In single doses, repetition of style and accessories may not be noticeable, but collectively it becomes immediately very marked. The stock of accessories should be large enough to prevent the repeating of a particular type of portrait too often, for to go back to our opening point many sitters object to being photographed in exactly the same manner as their neighbours. If, either from a lack of originality,

or from limitations in the amount that can be spent upon studio furniture, great variety is not always possible for a portrait photographer, the sitter should not know it, much less have it pointed out to her in the show case.

* * *

Legs in Portraiture. In the early C.D.V. days it was more often the custom of photographers to include in a picture the legs of a male sitter. There appears to have been some unwritten law compelling operators to picture a man from the top of his head, or hat, to the soles of his boots. Legs were as common in pictures then as they are rare to-day. Articles on posing hands have been plentiful enough in photographic literature, but information on posing legs has been rare—indeed, most rare—since the days of the late H. P. Robinson (who was in business during the leg-picturing era) and the late A. Horsley Hinton, both of whom had ideas on the subject. There is the authority of the Psalmist for the statement that "the Lord delighteth not in any man's legs," an attribute of divinity which photographers share. Limitation to head and shoulders of the sitter naturally guides the artist in the direction of concentrating his efforts on the head and face, which, after all, are the main things in portraiture. It has been stated that the "kit-cat" portraits of Kneller (36 x 28 in. half-length, showing hands) killed the art of picturing legs, and they may have done so in the world of artists of the brush, but Kneller died one and a half centuries before the C.D.V. craze. Anyway, legs and feet are now out of fashion in photographic portraiture, and may they remain so, unless, of course, someone comes along with a really artistic method of posing them.

APRIL PHOTOGRAPHY.

In all Government and in many other branches of business April 1 is the beginning of a new financial year, and, from the standpoint of general practice in this country, it might conveniently be regarded as the opening also of a new year for photographers, both professional and amateur. To both classes, no doubt, the date on which Easter falls is a consideration, and amateurs cannot but have been affected to some extent by the premature spring we were enjoying two or three weeks ago. But, speaking generally, the beginning of April marks the start of a fresh campaign for which, if the photographer be wise, he has already made his preparations, either for resuming work on last year's lines, or for striking out in some fresh direction. Whether professional or amateur he will have studied, and can hardly fail to have been influenced by, the captivating announcements with which our advertisement pages are always so freely studded in March, and this year apprehension lest some undue extravagance may have been committed is pleasantly alleviated by the reflection that at last the price of plates is on the down grade.

Apart from all these sternly practical features, April is for photographers a month of many special possibilities, some of which too often are carelessly neglected. It is a month of whims and fancies, not infrequently trying to the temper and occasionally causing material loss. "The uncertain glory of an April day" has produced many a photographic disappointment, and accounted for many a wasted hour. On the other hand, there is nothing in the year to surpass the loveliness of a fine interval between April showers, when everywhere there is that beautiful "clear shining after rain," for which more especially the telephotographer during the summer usually longs in vain. Where distances have to be rendered there is no atmosphere like that of a well-washed April morning, and in many cases much more satisfactory pictures of comparatively near objects can be taken this month than either earlier in the year when the trees are altogether leafless, or later when this or that attractive vista is closed by luxuriant foliage. For the flower photographer April caters less abundantly than May and June, but she has special gifts of blues and yellows to bestow on those who seek them discerningly, and with the right kind of light-filter. In which connection it may be wondered whether the application of orthochromatism to spring photography is yet as widely understood as it ought to be, and the occasional value of a green in place of a yellow filter fully grasped.

In April it is often possible to secure interesting lunar photographs without the aid of a costly equatorial movement actuated by a driving clock, and in this particular April we have the additional celestial attraction of an annular eclipse of the sun on the morning of the 8th. Of this not a few amateurs should be able to secure mementoes—weather permitting—and "summer-time" will in the case of habitual late risers extend the period during which exposures will be made. For it is much to be feared that if the clock were registering true time, any phenomenon short of an earthquake which began at 7.35 would drag a really creditable representation of confirmed lie-a-beds from their couches to photograph its earlier phases. To the average professional, by the way, the daylight saving which begins this month pleasantly accentuates the welcome advance from the comparatively short and unprofitable working days, even of such an exceptional March as we have just enjoyed. A calculation of the effective printing hours during the business days of April under summer-time regulations would show, we are inclined to think, an almost startling increase over the figures for the previous month.

But beyond a certain point, what may be called in the language of the Courts the case for April would be weakened by special pleading. It is a great month for photographers, largely because it is a great month for everybody, and it is a great month for everybody because it is spring, and one of those "new beginnings," the value of which is recognised by all sane persons. Shakespeare, in one of his sonnets, speaks of April as putting "a spirit of youth in everything," and it is well for photgraphers at least once a year to have a spirit put into them and their work which is as far as possible removed from senility and obsolescence. There are, as we all know, some workers who are perennially youthful, always bubbling over with fresh ideas, ever ready to keep abreast of the progressiveness of others. But the vast majority, while no doubt they would justly resent being called "back numbers," are needlessly reluctant to leave grooves in which they have been running for more years, perhaps, than has been good for them. April is the time for these to practise a little introspection, and to ask themselves seriously the question whether, either as professionals or amateurs, they are getting out of photography all they might easily get if there were more of the spirit of youth in their methods and output. We are the last to counsel fantastic new departures, and photographers ought to be the last, or nearly the last, to disregard convention to the extent of committing absurd extravagances in imitation of the younger and wilder artistic schools. But freshness is welcome in photography, even if it only be in minor things, and there is no reason why it should interfere with the expression of individuality. The note of freshness, too, is naturally best struck, and clearly struck, at a season when Nature, animate and inanimate, is responsive, and hope and brightness and the *joie de vivre* are in the very air.

A COMPARISON OF DEVELOPMENT METHODS.

Success in the development of a photographic plate involves the production of a negative whose printing range or scale either diminishes, imitates or exaggerates the range or scale of light-intensities in the subject in order to make them coincide with and utilise the whole of or an appropriate portion of the exposure range or scale of the printing paper.

The purpose of development is defined in that paragraph, and exposure completed, these are the only conditions to be fulfilled. Before considering to what degree of accuracy various methods of development lend themselves in the fulfilment of these conditions, it may avoid misunderstanding if the first paragraph be elaborated and the meaning of range or scale of the subject and the negative and the printing paper be defined.

The scale of a printing paper has nothing whatever to do with the number of tones which it is capable of rendering. The words scale or range applied to printing paper are contractions for "exposure scale" or "exposure range." The *tone* scale of every ordinary printing paper is approximately the same, and all papers which possess the same surface characteristics (matte, semi-matte, or glossy) have tones which extend from white of the same whiteness at one end to black of about the same blackness at the other end, and they have approximately the same number of shades of grey in between. Between the white of white paper and the black of a good photographic black the eye is capable of distinguishing about 100 different shades of grey. If a larger number of shades of grey be crowded in between white and black, they cease to be appreciated as separate tones, and imperceptibly run into one another. For all practical purposes photographic printing papers are equal so far as the multiplicity of the tones is concerned.

The exposure scale or range of a paper, however, varies a great deal between different types of printing paper (gaslight paper, bromide paper, etc.), and it is this variable characteristic which is referred to in the opening paragraph. The difference between one paper and another can be demonstrated in a very simple manner. If a piece of vigorous gaslight paper be placed in a printing frame and exposed to a printing light, an exposure can be found (by trial) which will, upon development, produce the faintest possible grey deposit. Call this exposure t seconds. Then it will be found that the exposure required to produce the deepest black upon the same gaslight paper would be about ten times as much, i.e., 10 t seconds. Any exposure less than 10 t seconds would produce a grey tone, and any exposure greater than 10 t seconds would be unable to produce a deeper black. The exposure range of that paper is 1—10, and it is that range of exposure which will enable the paper to exhibit upon development the whole gamut of tone from white to black. In between t seconds exposure and 10 t seconds exposure are an infinite number of possible exposures, of which 100 will produce the 100 possible shades of grey already alluded to. The exposure scale of vigorous gaslight paper is approximately 1—10.

If the same experiment be tried with a piece of bromide paper a different result is arrived at. If t' seconds be the time of exposure required to give rise to the faintest grey upon development, then about 40 t' seconds exposure is required to give the deepest black, a black practically no different to the gaslight paper black. And in between t' seconds exposure and 40 t' seconds exposure are 100 appropriate other exposures, which will give rise to 100 different shades of grey. The exposure scale of this bromide paper is 1—40.

Platinum paper has an exposure scale of about 1—100. If t'' seconds exposure give rise upon development to the faintest grey tone then 100 t'' seconds exposure give rise to the deepest black tone. Between these extremes of exposure are 100 other exposures which give the 100 intermediate shades of grey. The 100 intermediate shades of grey are approximately the same in each printing paper.

The exposure scales or ranges of a few representative printing papers are given in Table I. Average figures only are given, because different makes of paper vary considerably.

TABLE I.

Type of Printing Paper.		Approximate Exposure Scale or Range.	
Short Exposure scale.	Vigorous Gaslight Paper	1–10	Relationship between the extreme exposures required to record upon the paper from white to black.
	Soft Gaslight Paper	1–20	
	Average Bromide Paper	1–40	
	P.O.P.	1–60	
Long Exposure Scale.	Carbon	1–80	
	Platinum	1–100	

A negative is a graduated printing device. It is obvious upon inspection that different intensities of light pass through different parts of the negative according to the opacity of the various deposits of silver. Somewhere upon every negative is a portion more transparent than the rest. Somewhere else upon the same negative is a portion more opaque than the rest. There is a definite relationship in every negative between the amount of printing light that passes through the most opaque part compared with the amount passing through the most transparent part. This relationship is called the scale or range of the negative, and the terms have that meaning in the opening paragraph and throughout this paper. If through the most transparent part of the negative there passes 10 times as much printing light as there does through the most opaque portion, then the scale of that negative is 1—10. Such a negative is capable of just bringing out the tones from white to black on a piece of vigorous gaslight paper which has been shown to have an exposure scale of 1—10. Such a negative therefore is said to fit or suit vigorous gaslight paper. On the other hand, such a negative (1—10) would be useless for printing on platinum paper which has an exposure scale of 1—100, for if it were used it could only produce a few grey tones out of the whole scale of tones common to all papers. Similarly, a negative which allows 40 times as much light to pass through the most transparent part compared with the most opaque portion is described as having a range or scale of 1—40. Such a negative would be suitable for printing upon bromide paper of a similar exposure scale. If a 1—10 negative were printed on vigorous gaslight paper (scale 1—10), then obviously many of the dark grey tones would all be rendered as black, and many of the light grey tones would be rendered as white. We call such a print harsh. The scale of the negative is too long for the paper.

In general, the scale of the negative should coincide with the scale of the paper in order to produce a touch of white and a touch of black somewhere upon the finished print. If, however, for perfectly legitimate artistic purposes it is desired to utilise only a portion of the possible tones which any paper will yield it is only necessary to use a negative whose scale is *shorter* than the exposure scale of the paper by *some definite amount*, thereby producing a print exhibiting white and light greys, or greys and darker greys or dark greys and black, but not the full gamut of tones, white, light greys, dark greys, and black.

The subject (any subject) is merely a collection of different light-intensities. From a pictorial point of view the shapes and grouping of these different light-intensities (subject tones) alone are of importance. From a technical point of view, however, the shapes and grouping do not matter in the

slightest degree. Technically, the important characteristic of the subject which is relative to the subject-matter of this paper is the total range of light-intensities that the subject reflects, and which, through the medium of the lens, fall upon the plate in imitation of the subject. An ordinary landscape with the sun shining, presenting sunshine and shadow, exhibits a range of light intensities of about 20 to 1. The sky is probably the brightest part, and a foreground shadow the darkest. Under average conditions 20 times as much light is being reflected from the sky as is being reflected from the foreground shadow. These relative reflection powers are transmitted to the plate by the lens, and upon the plate during exposure is a sky image which is 20 times as bright as the image of the foreground shadow. The range of that subject, imaged upon the plate during the act of exposure, is 20—1. The same subject under different lighting conditions and other subjects can present different ranges. A few average subject ranges are given in Table II. The figures are, of course, rough approximations only.

TABLE II.

Subject.	Approximate range of light intensities.
Flat open landscape without sunshine or shadow	3–1
Landscape with dark object in foreground without sunshine	8–1
Landscape with dark object in foreground with sunshine and shadow	16–1
The most extreme lighting in ordinary outdoor work	32–1
Interiors and indoor portraits with marked highlights and deep shadows	40–1 to 100–1

These ranges of light-intensities in ordinary subjects are very different from the ranges which many photographers think that the average subject presents. It appears to be commonly thought that the sky is several hundred times as bright as the shadow side of a tree, for instance. It is as well for photographers that this is not so, because no photographic plate is capable of recording such a range. I would refer those photographers who still believe that a long range of light-intensities is commonly met with in photographic subjects to the papers on this subject by Hurter and Driffield,* whose conclusions have since been substantiated by other investigators. Hurter and Driffield showed that the photographic range from bright sky to black velvet at close quarters illuminated by diffused light was 32—1. The photographer is seldom called upon to deal with a greater range in an outdoor subject.

Whatever the range of light-intensities in the subject may be, it is that range which illuminates the plate during exposure. The negative which results upon development can imitate, exaggerate or diminish that range according to the length of time that it is developed. The range of the negative has already been defined as the relative transparencies of its lightest and darkest parts. Let us suppose that a subject has a range of 20—1. If the negative is developed for what we may call a medium or normal time (contrast or gamma=1), then we produce a negative whose range is exactly the same, namely, 1—20. If, on the other hand, we shorten the development time (contrast or gamma less than 1), we can reduce the range of the negative to anything we like according to the amount by which the time of development has been reduced. By reducing the development time to quite a little less than normal, a 20—1 subject can be made into a 1—10 negative. There is no loss of truth in the tones caused by this procedure: they are merely differently spaced. Similarly, by prolonging development beyond the medium or normal time (contrast or gamma greater than 1), the range of the negative can be expanded easily to 1—200 or more, far beyond any range required in ordinary photographic practice, again without loss of truth in the tones, for their spacing is merely extended.

We are now in the position to understand the purpose of development as laid down in the opening paragraph, and we can quote some illustrative examples. For the sake of ease in description, development to a contrast of 1 (gamma=1) will be called development to a normal time.

The subject has a range of 40—1. It is proposed to print on bromide paper. The exposure range of bromide paper is 1—40 (Table I.), so that the negative has to be developed for just the time to give a range of 1—40. But a 40—1 subject is reproduced as a negative of 1—40 range by a normal time of development. If the correct normal time of development is known, then the production of a good print on bromide paper of that subject can be accomplished by means of a negative developed for normal time.

Let us take the same subject whose range is 40—1. It is now proposed to print on vigorous gaslight paper. The exposure range of vigorous gaslight paper is 1—10 (Table I.), so that the negative has to be developed for such a time as will give a negative range of 1—10. In order that a 40—1 subject shall give a negative whose range is 1—10, the negative must be developed for some time *less* than normal. If the exact time less than normal is known, then the vigorous gaslight print will represent the subject in exactly the same manner as the bromide print did, but from a negative developed for a shorter time.

Take the same subject again (range 40—1). It is proposed to make a platinum print. The exposure range of platinum is 1—100 (Table I.). A negative has to be produced, therefore, whose range is 1—100. Such a negative can only be produced out of a 40—1 subject by developing for longer than normal time. If the precise longer time of development is known, then the platinum print will represent the subject exactly as did the bromide print and gaslight print. We have in these three examples shown that each printing process requires the negative to be developed for some particular time in order to represent the same subject in the same manner. In a similar manner a variation in the subject alters the time for which the negative must be developed. Instead of upon a subject of a 40—1 range, let us expose a plate upon a subject of a 10—1 range. Let us make a negative to print on bromide paper. Such a negative must have a range of 1—40. To make a negative whose range is 1—40 from a subject whose range is 10—1 requires development for a longer time than normal. So whereas in the first example given we fitted the subject to bromide paper with a normal-time developed negative, now we have to fit another subject to the same bromide paper by giving a long time of development to the negative.

It is abundantly evident, therefore, that the relationship between the range of the subject and the exposure range of the printing paper determines the degree of development of the negative. It is the purpose of any system of negative development to link the subject with the printing paper in the manner described. We can repeat the opening paragraph to emphasise its importance as a complete definition of the condition of successful development. *Success in the development of a photographic plate involves the production of a negative whose printing range or scale either diminishes, imitates, or exaggerates the range or scale of light-intensities in the subject in order to make them coincide with and utilise the whole of or an appropriate portion of the exposure range or scale of the printing paper.*

In the paragraphs that follow an attempt will be made to summarise briefly the reasons that combine to prevent the photographer from being able to carry out development with the precision necessary to fulfil these conditions with invariable certainty when development is carried out by inspection, or factorially or for a calculated time.

Development by Inspection.

The successful accomplishment of development by inspection implies that the photographer shall be able to judge, in the

* "Latitude in Exposure and Speed of Plates," "Photography," July 15, 1893; "The Hurter and Driffield System," "The Photo-Miniature," No. 56, November, 1903. Both these papers have been reprinted in "The Photographic Researches of F. Hurter and V. C. Driffield," published by the Royal Photographic Society.

light of a dark-room, what are the relative transparencies of the lightest and darkest parts of the negative, and thus estimate its range, and at the same time make allowance for the effect of the unchanged silver bromide which at a later stage will be removed in the hypo. If this could be done with reasonable accuracy, development by inspection would be ideal. The subject, the developer, the temperature of development, etc., could all be ignored. The negative would be developed until it was of the correct range to fit a chosen printing paper and announced its correct nature by its appearance, no matter for how long or short a time it required to be developed to give that appearance. But it is an unfortunate fact that the range of a negative is a characteristic beyond the power of the eye to compute. Those photographers who have actually measured the range of a fixed dry negative in a density meter devised for the purpose know well how impossible it is to estimate the range by simple inspection. What is impossible in good light with a fixed and dry negative is not rendered possible in the dim light of a dark-room, with an unfixed negative. There are experienced photographers, however, who do succeed in developing by inspection successive negatives to a predetermined range with a moderate degree of accuracy. To what extent they conceal their failures remains unknown. For the most part, however, these successful photographers confine their work to one class of subject (in which the range does not vary very much), illuminated by artificial light of reasonable constancy, so that successive exposures are approximately of equivalent value, and the negatives are destined for the same printing process. Under these narrow conditions, the *general* appearance of the negative during development becomes a crude measure of its range. Skill in imitating this general appearance from day to day comes to a few photographers with experience, and these narrow conditions account, in my opinion, for the success with which development by inspection can be practised by certain workers. But the nature of the problem of development, already described, is such that it is certain that for mixed work and for the utilisation of any printing process at will, precise development by inspection with certainty is an impossibility. If the nature of the problem of development were more universally understood I do not doubt that many photographers whose work is of a mixed nature would feel less confident of their skill in development by inspection, and they would more readily give credit to the part played by chance.

B. T. J. Glover.

(To be continued.)

SUCCESS IN GLAZING.

Notwithstanding all that has been said and written about glazing, there seem to be many photographers, both professional and amateur, who still find a considerable difficulty in obtaining anything like perfect results. Perhaps it is the very simplicity of the process which to a large extent accounts for this lack of success. When a thing seems easy one is too apt to deal with it in a haphazard sort of way, thinking that it is sure to come right in the end. Habit is habit all the world over, and most people have got a habit of scamping little things that appear to be easy. It is just as necessary to be thorough in work that is easy as in that which we acknowledge to be difficult. Unless we put our energy, and our thoughtful energy at that, into a small matter like glazing we are just as much liable to failure as if we went carelessly to work in a much larger enterprise. In point of fact, most photographers leave the glazing work in the hands of boys or girls at a small salary. Boys and girls just fresh from school and with their minds more set upon play than work consider, or most of them do, that they have been going through a hard time at school, and that they are now entitled to a good time for a little while before settling down to the real business of life; consequently, the work with which they are entrusted is scamped, and what good results are obtained are obtained at a cost far heavier than if more staid and better paid assistants were employed.

You go into a room where three or four or more girl assistants are working (sic) and what do you see? At one end of the bench or sink you will find the first girl with one hand resting on the bench and with the other supposed to be applying the French chalk or glazing solution to a glass in front of her, but upon which her eyes never rest, as her head is turned towards the next assistant with whom she is carrying on an animated conversation with reference to the doings of the previous evening or, at any rate, with reference to something totally unconnected with the work in hand. Is it likely then that the glass will be properly prepared, that the edges will not be missed, or is it likely that Assistant No. 2, who takes the glass from her to lay on and squeegee the prints, will do much better towards her portion of the work? If the prints stick, well it couldn't be their fault. It must have been bad paper or a fault in the drying room.

It should be borne in mind that the process of glazing, though as I have said it is a simple one, is not a single one; it is not for instance like fixing a print, it is a compound process made up of several processes, each simple enough in itself, but each and all requiring the exercise of care and attention; without attention and without care in any one of the minor processes the whole compound process will prove a failure.

In the first place it is necessary to have a *clean* glass, one imperfectly cleaned, one that is greasy or dirty or finger-marked will not do; then it is equally necessary that the glass shall be properly and carefully prepared either with French chalk or glazing solution. Also, that the print or prints are clean when laid on the glass, and that they be properly squeegeed, without air bubbles being left, and so on throughout until the prints are off the glasses and out of the hands of the glazing superintendent, when his responsibility finishes.

To obtain a really clean glass it should be washed and polished, with methylated spirit, water will not do, and to test its actual cleanliness there is no better method than one which all old collodion workers will recall, viz., breathing on the glass; if perfectly clean, the breath will dry off readily and evenly; if any trace of dirt remains it will be seen at once and its position located. The glass being now clean the next part of the process is to prepare it for the reception of the print or prints. The method of preparation differs with different workers; some prefer French chalk, others one or other of the advertised glazing solutions, others, including myself, prefer a home-made solution of ox gall, and some few cling to powdered white starch or petrol. In the case of a small business, such as a studio, there is nothing to be said against the use of French chalk, which should be dabbed well all over the glass with a pad and then polished off with a clean linen rag. The first time of using the glass this part of the process should be repeated at least half-a-dozen times before the prints are laid on. Once the glass is in use a single careful application will be found to be ample. The glass being now ready, the print should be carefully swabbed over the face to remove any trace of dirt or grit, and then laid in its position on the glass. If a number of small prints are to be glazed on the one glass care should be taken not to place them in too close juxtaposition. The glass being filled, a piece of rubber sheeting is laid over all and squeegeed with a flat squeegee, preferably one of soft pine or, at any rate, fairly thick rubber; most of those on the market are too flimsy. In squeegeeing,

be careful not to keep continually crossing the sweeps as that will churn any one air bubble up into twenty or more small ones. The print or prints being squeegeed and examination through the glass showing that the contact is perfect, a piece of linen sheeting or of blotting board should take the place of the rubber sheeting and be squeegeed with a roller squeegee to remove superfluous moisture and facilitate the drying process. The roller squeegee should be a genuine tool, not one of the toy type which jump from their gearings directly any real pressure is applied. The glass is then ready for transfer to the drying rack.

Where one of the glazing mediums is used in preference to the French chalk the only difference in procedure is with the first part of the process: the polished glass is coated on both sides, with the medium by means of a well-soaked rag, or preferably with a small mop such as are used for cleaning lamp glasses; the medium in this case should be made up of at least double strength, and the glass is then placed in the rack and allowed to dry, care being taken to keep it free from dust during the drying. The prepared glass, when dry, should be again treated with the medium, and the prints placed thereon, the process proceeding as with the French chalk. Most of the mediums in the market are good, but the home-made is preferable on many accounts, not the least of which is the difference in cost: at the present price of labour, bottles, printing labels, packing, advertising, and carriage, to say nothing of manufacturers' profits, it stands to reason that a home-made product must be materially less costly. The method of manufacture is as follows:—To the contents of one ox gall, to be obtained of most English butchers at a cost of about sixpence, add one gallon of water, two ounces of glycerine and two drams of formaline. This will keep almost indefinitely in a stoppered bottle, the quantity required for use each time being poured therefrom into a jar or basin in which the rag used for applying is soaked. This is the ordinary strength for general use; for the first application to new glasses only half a gallon, or less, of water should be used. Powdered starch, petrol, etc., are more or less the cause of trouble, and cause markings on the finished prints, and their use is not advisable. It should also be noted the extra thick paper, such as postcards, requires much more care in squeegeeing than the ordinary grade used for portraiture or other work that is to be mounted on card.

Having our prints all on glass, we are not yet through, as great care is still requisite in the drying to ensure perfection, especially in damp weather, where artificial heat has to be used; the best method of warming a drying room is undoubtedly by means of hot water or hot air pipes, the warmed air being kept in motion by electric fans. The next best method is by means of an ordinary coal or coke fire. Only when unavoidable should gas be used as a means of heating, and whatever method is employed, the glasses should never be brought too close to the source of heat. The drying should proceed gradually and evenly, five to six hours is not too long a time for paper of postcard thickness; any attempt to rush the prints off the glass too rapidly is merely courting disaster. A difficulty sometimes arises with regard to the glasses filled up during the evening, as they have, perforce, to be left unattended for from fifteen to sixteen hours, during which they are subject to changes of temperature; and, what is more to the purpose, changes of the amount of moisture or damp in the air. It will therefore be found necessary to see that the fire is made up last thing, so that the temperature may not fall too much before it can be attended to again. The danger in question, is, of course, accentuated in regard to the prints which are put on glass on the Saturday, and have to remain thereon until Monday, i.e., unless they become detached and fall off the glass of their own accord. It will always be found that the greatest percentage of failures in glazing is among these Saturday-to-Monday prints. It would seem that the ox gall after once drying loses its power if it again becomes damp, and consequently there is a considerable chance of the prints becoming difficult to detach from the glass support.

During and since the Great War, there has been considerable complaint of an epidemic of small specks appearing on the finished prints, and many reasons have been given for their appearance, but so far no real preventive or remedy has been adduced. Be the cause what it may, I personally opine to the belief that, it is either imperfect coating with or use of impure baryta or imperfect admixture of two or more gelatines, hard and soft. Soaking the prints, before glazing, in hot water, in cold water, in formaline have all been suggested as remedies, or rather preventives, but have none of them proved an absolute success. Such being the case, I would recommend a real remedy, which is after the prints are glazed, and show the specks or spots in question, to coat them with a very dilute copal varnish to which a small proportion of turpentine has been added.

Before leaving the subject, I would remark that in the dry, warm weather which we hope to see ere long, the drying racks may be placed in the open air with good results.

C. Brangwin Barnes

THE MORDANT DYE PROCESS FOR COLOUR TONING.

[In several communications of late to the "Colour Photography" Supplement of the "British Journal," viz., January 7, 1921, p. 3, November 5, 1920, p. 43, and June 4, 1920, p. 24, Mr. F. E. Ives has published the results of his experiments in dye-toning by a mordanting process for the production of three-colour transparencies. In the following note he describes further details of this process in particular application to single colour toning of transparencies on glass or celluloid.—Eds. "B.J."]

The mordant dye process is not suitable for colouring prints on paper, but for prints on glass or celluloid it offers the advantage that the solutions used are very much cheaper than the chemical toning solutions, and keep good until exhausted by use. There is also the advantage that a practically unlimited variety of colours and tones can be obtained.

My earlier experiments were directed mainly to the production of pure transparent colours for trichromatic and colour cinematograph work, and after mastering this problem attention has been directed to perfecting the application and control of the process to toning and tinting, particularly for cinematograph positives, but also for lantern slides.

For this purpose it suffices to further reduce the strength of the bleaching solution and the time of immersion, so that no bleaching action is evident to the eye, though there has been sufficient action to fix the required amount of colour from the dye bath.

It is even possible with a number of basic dyes to mix a little of the normal bleaching solution with the dye solution without precipitaion, and so to be able to watch the progress of the toning and stop it at the desired point. I do not recommend this procedure because it limits the choice of dyes, and is, after all, no quicker or better than the method by successive operations.

The bleaching bath which I recommend for this purpose is as follows:—

Water	30 ozs.
Potassium ferricyanide	5 grs.
Ammonium bichromate	1 gr.
Glacial acetic acid	¼ oz.

To insure even action I prefer to immerse the positives dry, and the time of immersion may vary from 30 seconds to two minutes, according to the amount of colour desired in the finished result. Five minutes' washing is desirable before immersion in the dye bath. Good dyes to use are malachite green, saffranine, phenosaffranine, rhodamine, auramine. Stock solutions may be made up with one grain of dye to each four ounces of water, and a little acetic acid. These solutions can be mixed to produce a great variety of tones.

The amount of colour mordanted depends not only upon the time of immersion in the bleach, but upon the time of immersion in the dye bath; the best results are obtained with short immersion in the bleach, and long immersion in the dye bath—half an hour or more for some dyes. With a suitable amount of acetic acid in the dye bath (the requisite amount depending upon the dye used) a few minutes' washing in plain water after dyeing clears the whites perfectly. If a tint is desired in addition to the tone, this washing is omitted.

It is an interesting fact that extremely fugitive dyes produce quite permanent colour prints by this process.

I venture to predict that by reason of its unrivalled simplicity and economy, this method will supersede all others for colour-toning on glass and celluloid.

F. E. Ives.

THE MORDANT DYE PROCESS FOR NEGATIVE INTENSIFICATION.

In a separate communication I point out that a diluted bleaching bath without sufficient action to bleach the silver image visibly would prepare it for taking up a large amount of basic dye from solution. This is the procedure recommended for "toning" silver images. It is obvious that if the dye used is of a non-actinic colour it will act as an intensifier, and the process can be employed in negative making for that purpose, giving a greater range of densities and more control of density probably than any other method.

For general use in intensifying, I recommend a mixture of victoria green and saffranine dyes, which in suitable proportions produce a near-black colour by which the degree of photographic density can be closely estimated by the eye. Different makes of dyes vary somewhat, but I am using—

Water	30 ozs.
Victoria green	2-1/2 grs.
Saffranine	5 grs.
Glacial acetic acid	1/4 oz.

The process is very cheap, and the solutions keep indefinitely, but the time which it takes to dye up and subsequently clear the image, particularly on thickly-coated plates and non-curling film, makes it unsuitable for "hurry" work.

For some special purposes, however, it is superior to any other method of negative intensification. Thus, by a single (complete) bleaching operation and a single dyeing, more printing density can be imparted to dry plate line or half-tone process negatives than by any other means. It adds much to the value of the method for that purpose that the dye print can be cleared and reduced as readily as an ordinary negative can be by Farmer's solution. The mordanting substance, silver ferrocyanide, is extremely soluble in hypo, and a solution as weak as one grain to the ounce acts upon the dye image like Farmer's reducer upon an ordinary negative. Knowledge of this fact also shows the importance of washing out all hypo from the film before immersing in the bleaching bath, and avoiding any trace of hypo in the subsequent handling, except as indicated. The presence of chlorides and bromides is also contra-indicated.

F. E. Ives.

PHOTOGRAPHIC DEALERS' CONGRESS.

The Congress, arranged by the Photographic Dealers' Association, will be held during the Photographic Fair at the Horticultural Hall, Vincent Square, S.W., according to the following programme:—

Monday, April 18, 2.30 p.m.—Annual meeting, to be held in the Congress Room, Photographic Fair, Horticultural Hall. Business:—Annual report and balance-sheet, election of officers. 6.30 p.m.—Annual dinner. This will take place at the Holborn Restaurant. Tickets, 10s. 6d. Morning dress. Ladies invited.

Tuesday, April 19.—Visit to the Houghton-Butcher Camera Works, Walthamstow. By the generous invitation of the Houghton-Butcher Manufacturing Co., Ltd., Congress members will be conveyed to Walthamstow by char-à-banc, leaving the Photographic Fair, Horticultural Hall, Vincent Square, at 11.30 a.m. Lunch will be served on arrival at the factory, when parties will be arranged, accompanied by guides, to see the works.

Wednesday, April 20, 2.30 p.m.—Dealers' Congress, open to members of the P.D.A., in the Congress Room, Photographic Fair, Horticultural Hall. Subjects for discussion:—

1. The high price of plates and papers and the effect on amateur photography.
2. Should Co-operative Societies be granted dealers' terms?
3. On what terms should professional photographers be recognised as dealers.
4. Are pre-war trade discounts sufficient to-day?

Thursday, April 21.—Visit to Messrs. Ross' Works, Clapham Common, S.W. By the kind invitation of Messrs. Ross, Ltd., Congress members will meet at the factory at 12 a.m. Luncheon will be served on arrival. Members will afterwards be arranged in parties and conducted through the works. Clapham Common can be reached by L.C.C. trams from the Embankment, or by the City and South London Railway from any tube station to Clapham Common Station.

Friday, April 22, 7 p.m.—In Congress Room, Photographic Fair. Lecture on "Window Dressing as a Selling Force and its Application to the Photographic Trade," by Mr. E. Willson, of Messrs. Kodak, Ltd., President of the British Association of Display Men, and winner of the £100 prize in the National Window Dressing Competition at the Advertising Exhibition, White City, 1921.

The lecture will be illustrated by lantern slides, and by arrangement with Messrs. Kodak, Ltd., will be open to photographic dealers and their assistants, admission on presentation of business card.

Congress meetings can be attended only by individual members of the P.D.A. A special Congress fee of 5s. entitles members to attend the meetings on Tuesday, April 19, Thursday, April 21, and also includes admission to the Photographic Fair. All applications for dinner and Congress tickets must be accompanied by a remittance, and addressed to Mr. J. E. Hodd, 119, Victoria Street, S.W., not later than Monday, April 11.

Photography in the Navy.—Details are published in Admiralty orders of the examinations to be passed by seamen and marines who wish to join the new Photographic Branch, established in November, 1919. Photographers, first class, receive 1s., and second class, 6d., per day as specialist pay. All men at present holding the rating of acting photographer, first or second class, and all volunteers in future, are required to pass an examination, both written and practical. Candidates for the first class rating have also to pass a test in cinema work. In the Atlantic and Mediterranean Fleets an examination will be held every six months, the dates being arranged and promulgated by the respective Commanders-in-Chief. The tests will be conducted by the Fleet Photographic Officer, or, if none is borne, by the Photographic Officer in the target-towing sloop. On stations abroad or in ships at home, where no Fleet or Sloop Photographic Officer is serving, the names of candidates are to be sent to their respective depôts and also to the captain of the gunnery schoolship "Excellent," where a roster will be kept of all men who have qualified, and where men will be nominated to fill vacancies in the branch as they occur.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, March 14 to 19:—

COLOUR PHOTOGRAPHY.—No. 8,333. Relief colour photography. H. E. Dawson.

FILMS.—No. 8,107. Sensitised photographic films. C. V. Drysdale, J. H. Powell, and A. Wood.

ENLARGING EASEL.—No. 8,024.—Photographic enlarging easel. Wallace Heaton, Ltd

COLOUR PHOTOGRAPHY.—No. 8,590.—Method of producing photographic plates for indirect tri-colour photography. E. A. Lage.

CINEMATOGRAPHY.—No. 8,236. Cinematograph apparatus. J. G. Betjemann.

CINEMATOGRAPHY.—No. 8,401. Apparatus for developing, fixing, toning, tinting, and drying cinematograph films. A. Bourdereau.

CINEMATOGRAPHY.—No. 7,953. Day or night screen and film for moving pictures. T. H. B. Gayner.

CINEMATOGRAPHY.—No. 8,545. Moving pictures. M. Hall.

CINEMATOGRAPHY. — No. 8,474. Cinematographic projection. M. A. J. Harper.

CINEMATOGRAPHY.—No. 8,102. Cinematograph machines. H. Hevey.

CINEMATOGRAPHY.—No. 8,312. Cinematograph projection machines. M. H. Morris.

CINEMATOGRAPHY.—No. 8,352. Cinematograph apparatus. K. de Proszynski.

CINEMATOGRAPHY.—No. 8,353. Cinematograph mechanisms and films. K. de Proszynski.

CINEMATOGRAPHY.—No. 8,241. Cinematograph, etc., projecting apparatus. R. Wellesley.

STEREOSCOPIC CINEMATOGRAPHY.—No. 7,956. Apparatus for making and method of projecting stereoscopic cinematograph pictures. F. L. Rose.

CINEMATOGRAPH-PHOTOGRAPH. — No. 8,400. Synchronisation of machines for recording and reproducing sounds and movements. C. H. Verity.

X-RAY APPARATUS.—No. 8,096. Apparatus for production of X-rays. E. E. Greville and F. W. Read.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

MOSAIC COLOUR SCREENS.—No. 158,670 (Nov. 7, 1919). The invention relates to multi-colour screens for natural colour cinematography and still photography, of the kind in which coloured particles are used in conjunction with a tacky substance to form the colour screen upon a suitable transparent base. The coloured grains are mixed into a paste with a liquid tacky material, of a composition which will not impair the colour of the grains, and with this paste a suitable film of glass or other convenient material is coated. The grains or particles may comprise threads or particles of glass or other suitable transparent or translucent material capable of being coloured, but of such a nature as to repel or to resist any dye that may be applied to the liquid tacky material.

When, for example, a two-coloured screen is to be produced the grains or particles will be all of one colour and will be mixed into a paste with a tacky substance such as gelatine, fish-glue, or other like material which will not dissolve the grains, and which is dyed with another colour with a suitable dye solution, preferably warmed to, say, 60 deg. F., in order to soften the gelatine. The paste is then applied to the film or base, and the outer surface of the screen cleaned and dried in order to remve any dye that may be adhering to the surface of the particles, the result being a two-colour screen ready for any desired operation.

In a similar manner a screen or film of three colours, five colours, or other desired number of colours may be produced by employing grains or particles of the requisite plurality of colours.

If desired, the prepared surface of the screen may be protected with a suitable transparent varnish or other medium.

The grains may, if desired, be formed by dissolving a gum or like substance such as gum sandarac in alcohol or other solvent, the solvents being dyed any colour and then driving off the solvent so as to leave the coloured gum, which is then crushed to form particles

For dyeing the grains dyes are used which will be dissolved in the same solvent as that for the gum employed.

In order to facilitate the mixing and spreading of the pasty mixture formed from the tacky substance and coloured grains, glycerine is preferably added to the mixture.—John Camiller, 8, Wykeham Mansions, 20, Rosendale Road, West Dulwich, London, S.E.21, and Adam Hay, of 49, Old Bond Street, London, W.1

New Apparatus.

The Movie Camera Attachment. Made by the Movie Photo Co., 20, Cornhill, Bridgwater, Somerset.

THIS is a piece of apparatus for the making of the so-called "living portraits" which during the last few years have become an attractive photographic novelty in many places. It is an attachment somewhat resembling a repeating-back, which can be used in conjunction with a well-built studio camera, and allows of the necessary three negatives being made with great accuracy through the ruled screen. Perhaps it is necessary to explain to some that the living portrait is made from a negative containing three successive photographs, each of a different expression of the sitter's face, and existing as band images of width about 1-100th of an inch. This negative is made by exposing the plate three times in succession under a ruled screen, in which the opaque bands are twice the width of the clear spaces, the screen, or the plate, being shifted parallel to itself the width of the clear space between each exposure. From this negative a print is made by contact, and is then viewed through a similar ruled screen in close contact with it. A shift of the screen then discloses in turn the sets of bands representing the first, second, and third exposure.

It will be clear that, for successful results, strong and even pressure between the screen and the plate during exposure is necessary, as is also exact and strictly parallel movement of one or the other. In the apparatus before us the plate is moved by a cam, which operates upon a stout brass carrier very accurately guided by a pair of grooves. The successive movement of the screen into the second and third positions is most simply made by pushing across a lever, on the outside of the plate holder, into slots provided for it. The apparatus is most solidly and substantially made, as it requires to be for close contact between the screen and the plate. The plate holder travels on a back frame, which is fitted to the camera as a repeating-back is fitted. This back frame also accommodates a focussing screen, which is quickly drawn away and the plate holder brought into position. The apparatus is made for using the half of a half-plate, on which three negatives, each measuring about 2 inches square, are obtained. The plate holder is provided with a series of stops, by which it is brought accurately into position for the exposure of each successive third of the plate.

We are able to express the highest opinion of the design and construction of the outfit, the price of which is £12 12s.; and the Movie Company also supply a clockwork apparatus to be used as a window display of the "changing" character of the portraits. The price of this latter is £2.

New Books.

THE PHOTOGRAPHIC INSTRUCTOR.—The manual of this title, written by the late Mr. J. I. Pigg, has been brought out in a sixth edition by Messrs. Chapman and Hall at the price of 3s. 6d., which is not dear for a book of 250 pages, even in the paper covers which many publishers of technical works are now adopting, by reason of the abnormal charges for cloth binding. Mr. Pigg's text book, which has been revised and extended by Mr. P. R. Salmon, occupies a place of its own. While it deals with the elements of the technique of everyday negative-making and printing, it contains chapters on special branches of work which, as a rule, are left untreated in the average photographic primer. Such special branches are stereoscopic photography, orthochromatic and colour photography, photo-micrography and telephotography, and even cinematography, and process and X-ray work. The chapter on printing processes likewise deals with methods other than the ordinary ones, and provides sufficiently explicit instruction in carbon and Platinotype, gum bichromate, and oil and Bromoil. Those parts of the book requiring to be brought up to date have evidently benefited by Mr. Salmon's revising hand, and perhaps nowhere so noticeably as in the pages on the factorial and time methods of development, which are presented to the reader in eminently practical form. The manual is one providing accurate guidance in almost every branch of photography, and is well illustrated and printed.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, APRIL 4.

Bradford Photographic Society. Annual General Meeting.
South London Photographic Society. Annual General Meeting.
Willesden Photographic Society. "Personal Practice in Pictorial Printing." E. C. Perry.

TUESDAY, APRIL 5.

Royal Photographic Society. Ordinary Meeting. "Chemical Methods in Photography." C. M. Thomas, M.A.
Exeter Camera Club. R.P.S. Affiliation Competition Prints.
Manchester Amateur Phot. Soc. "The Present-Day Importance of Photography." A. Dordan-Pyke.
Portsmouth Camera Club. H. Van Wadenoyen's Portfolio.
Rotherham Photographic Society. Annual Meeting.

WEDNESDAY, APRIL 6.

Croydon Camera Club. "Colour Vision." F. C. Reynolds.
Dennistoun Amateur Phot. Assoc. "Carbro." A. C. Cairns.
Edinburgh Photographic Society. S.P. Federation Portfolio.
Ilford Photographic Society. "Kew in Colour." W. Lambert.

THURSDAY, APRIL 7.

Camera Club, The. "The Stormy Adriatic." W. C. F. Anderson.
Dundee and East of Scotland Phot. Soc. "Tricolour Photography." G. D. Charlton.
Everton and District Photographic Society. "Development by Time and Tank." A. Dordan-Pyke.
Hammersmith (Hampshire House) Photographic Society. "From Alps to Appenines." J. Dudley Johnston.
Kryn and Lahy (Letchworth) Phot., etc., Soc. "A Lesson in London."

FRIDAY, APRIL 8.

Bedford Camera Club. "Colour Slides." Paget Co.

CROYDON CAMERA CLUB

Dr. G. H. Rodman, F.R.P.S., gave an exhaustive lecture on "Spiders: Their Structure and Habits."

A feature of the evening was undoubtedly furnished by the gyrations of a spring-awakened fly, which examined the enlarged spiders on the screen with supreme indifference, if not contempt, and occasionally settled on the canvas to obtain a better view. Ultimately, coming within the sphere of a ventilating fan, it suddenly remembered an engagement elsewhere.

Another feature consisted of a gallant but abortive attempt to secure the usual half-time interval at the end of a solid hour of spidery lore. The lanternist, Mr. George Washington Walker, did his best by proclaiming that only a few minutes' life was left for the arc carbons, demanding an immediate change. On Dr. Rodman placidly disregarding this warning, and proceeding, they nobly rose to the occasion and worked yet another hour without turning a hair. A few present, who had neglected to make spiders a special study, expressed a sincere wish in the direction of compression, though they and all bore witness to the highly interesting and instructive character of the lecture, and admired the doctor for his thoroughness and enthusiasm in a fascinating branch of natural science.

The subject can hardly be said to be photographic, but one analogy may be mentioned. The retina of a spider's eye has ranged behind it crystals, which reflect the light and reinforce vision. The extra "vision," comparable with halation, obtained in somewhat similar way by a dry-plate, has nothing to recommend it, though many years ago a quasi-scientific journalist had the hardihood to start a discussion—"Does Backing Slow a Plate?" A most hearty vote of thanks was accorded the ever-welcome visitor from Richmond.

CLIFFORD CAMERA CLUB.—On 23rd inst. at the Club's Headquarters, Mr. H. H. Featherstone, F.R.P.S., gave a demonstration and lecture on desensitising plates before development. The preparation he used was one he had found as the result of numerous experiments, but it was understood to be similar to "Desensitol." The advantage he claimed was that while equally efficient as a desensitiser the stain left by his preparation disappears more readily during fixing and washing. Mr. Featherstone emphasised the fact that the sensitiveness of plates can only be reduced—not destroyed—by his and similar preparations, and the object of their use is not to abolish dark rooms, but to render them more comfortable by permitting more generous illumination. He said one desensitising bath should not be used for more than three plates, as its action was impaired and finally stopped by bromine absorbed from the emulsions, and development should not be prolonged beyond three minutes. The solution appeared to act by dyeing, and longer immersion in developer, he thought, bleached the deposit of dye, and left the plate once more liable to fog.

After the process had been described and questions answered, a flashlight photograph of the audience was taken. The exposed plate was bathed in desensitiser in darkness, and placed in developer together with an unbathed unexposed plate. A lamp fitted with a yellow, bromide safelight was then switched on close to the developing dish, and development completed. The flashlight negative was quite free from fog while the other plate appeared hopelessly fogged.

Mr. Featherstone then received a hearty vote of thanks, and the meeting concluded.

Commercial & Legal Intelligence.

LEGAL NOTICES.—A first and final dividend of 15s. 1d. in the £ has been declared in the case of Thomas Gillies Gaulen, commission agent, late photographer, Moorhurst, Whitminster, Gloucestershire, lately Hayne, Avenue Road, West Hartlepool, and 47, Church Street, West Hartlepool. The dividend is obtainable at the Official Receiver's Office, 26, Baldwin Street, Bristol.

CITY SALE'S 180-PAGE LIST.—The magnitude of the dealings of the City Sale and Exchange is exemplified in a list just issued by the branch of the firm at 81, Aldersgate St., London, E.C.1, which runs to over 180 pages. A few of these are occupied by a brief history of the firm, but nearly all contain closely-printed particulars of hundreds of pieces of apparatus in each of the various classes of cameras, lenses, enlargers, etc. The list is sent free on application.

News and Notes.

Messrs. John Harrap and Son advise us of the establishment of a special department at 3, Holborn Buildings, London, E.C.1, for picture, photographic, or advertising frames.

Royal Photographic Society.—In connection with the new studio now being fitted up at the house of the Royal Photographic Society, 35, Russell Square, Messrs. Houghtons, Ltd., have generously presented a handsome background with supporting frames and rollers to the Society.

Photography and Advertising.—Mr. Elwin Neame, the well-known West End photographic artist, is to lecture before the Publicity Club of London at the Hotel Cecil on Monday, April 4. Mr. Neame, who is bringing a "live model" with him, is dealing with the influence of photography on advertising. A cordial invitation to attend is issued to all publicity men interested, who should 'phone Mr. Day, Central 11769, for free invitation tickets.

The Professional Photographer for March reflects in equal intensities the artistic and commercial sides of photography. Mr. F. C. Tilney has one of his illuminating chapters on composition in portraiture, and there are examples of the virile work of the Swedish portrait photographer, Ferdinand Flodin, of Stockholm. On the commercial side, the importance of photography to the manufacturer receives an impressive testimony from Mr. S. Grimshaw, official photographer to the Ford Motor Co., of Manchester.

Quiagraph While-You-Wait Camera.—A descriptive circular of this latest camera for the making of direct-positive portraits is sent to us by the Quta Co., 252-254, Haydons Road, Wimbledon, S.W.19. It carries 50 plates ($2\frac{3}{8} \times 1\frac{3}{4}$), which are loaded in daylight, and is provided with direct focussing and with tanks for development and fixing while the customer waits for the necessary minute or two. The camera, which is priced at £8 8s., is evidently deserving of the attention of those in the ferrotype portrait business.

London Camera Exchange.—The issue of a 50-page catalogue of second-hand apparatus definitely marks this firm (Robbins, Manistre and Co.) among the leading establishments which specialise in the purchase and re-sale of cameras, etc. The partners know their business thoroughly well, and we applaud their policy of dealing only in goods which they can offer with confidence. The catalogue specifies a very great variety of camera, lenses, enlargers, etc., and is obtainable free on application to 2, Poultry, Cheapside, London, E.C.2

Nottingham Photographic Society.—The 17th annual exhibition will be held on April 28, 29 and 30, in the Albert Hall Institute, Derby Road, Nottingham. The closing date for entries is April 13, and all pictures and slides must be delivered by Monday, April 18. There will be an open section, as well as a section for the members of the Society only. Further information and entry forms may be obtained from the hon. sec., Mr. A. Beeston, 103, Nottingham Road, Nottingham. Mr. F. W. P. Simpson, of Loughborough, will judge.

Dye-image Negatives.—According to a patent specification, No. 156,691, open to inspection but not yet accepted, of the Ullmann Gesellschaft, Zwickau, Germany, in the production of dyed bichromated colloid negatives from opaque originals, in order to obviate a loss of sharpness when the developed negative is dyed, and to render it waterproof, the negative is dyed and then bathed in a solution which will convert the dye into a water-insoluble compound. As an example, the negative is dyed in a solution of penta-methyl-p-rosaniline and then bathed in a dilute aqueous solution of di-amido-stilben-disulpho-acid-diphenol.

Guilleminot Papers.—M. Jules de Gottal, 17, Cecil Mansions, Marins Road, London, S.W.17, sends us samples of two of the development papers manufactured by MM. R. Guilleminot, Boespflug and Co., of Paris, for whom he is agent in the United Kingdom. These are the "Aero Contraste," a bromide paper giving vigorous prints or enlargements from weak negatives, and the "Sedar," a bromide emulsion, which, by straightforward development with M.Q. yields prints of rich, warm black to brown colour comparable with those on platinum-toned collodion print-out paper. Both papers are evidently of high-class manufacture.

Correspondence.

HALATION: PLATINOTYPE.

To the Editors.

Gentlemen,—May I once more suggest that the best preventive of halation is to use a double-coated plate the lower (the slow) emulsion absorbs whatever halation may get in from the glass; and it is surprising what, in all average cases, a complete absence of halated effect can be expected, and that without any messy backing. Of course there are subjects that a backing, in addition, may be advisable for: such as a strong light coming directly through a window in the subject; but this even will give little trouble, though it should always, if possible, be minimised by waiting till the light comes *on* rather than *through* the window. The virtues of the double-coated plate have been my song for very many years but they are still comparatively unknown. All makers should list them; they would then be tried for at least difficult subjects, and once tried they would never be abandoned by those in search of quality; immunity from over-exposure; the ability to use the full exposure that alone gives the perfect negative of perfect exposure to all parts of the subject; deep shadows and high lights alike being perfectly rendered on a double-coated plate.

Platinotype.—I frequently find as in your last issue, that a thin negative is advised for Platinotype printing. This is directly contrary to my experience. I work for a very fully exposed negative, slightly under-developed and then intensified with mercury and sulphite of soda just sufficiently to separate the planes and give a strength of image that will make judging the degree of printing easy, easier than is at all possible with a thin negative. Perfect timing of the degree of printing is the crux, the real difficulty in Platinotype printing, and only an image rich in gradation and strong in transparent densities will ensure it.—Yours faithfully,

Frederick H Evans

Acton, W.3.

A STUDIO LIGHTED FROM THE SOUTH.

To the Editors.

Gentlemen,—Your leading article on a studio light from the south, west, or east is interesting and valuable, and suggests means of managing an admittedly difficult light. In America I believe it is not at all uncommon to use a sunlit studio, and I remember many years ago calling to see an American photographer who had just opened a studio in the West End of London in an old mansion. He received me most courteously and showed me his two studios, which were originally conservatories on the south side of the house. I suggested that he might find some difficulty in managing to work with a south aspect, but he said that in his studio in San Francisco he used a south light, and with proper arrangements of blinds and curtains his operators found no difficulty, after some experience, in getting any kind of lighting they desired.

It did not occur to me until some time afterwards that a south light could be managed with ease in a climate of comparatively constant sunshine, such as I imagine San Francisco enjoys; but in our land of sunshine and cloud, with those glorious clouds chasing each other across the blue (which give our English landscape one

of its greatest charms, when "waves of shadow went over the wheat"), a south light would be most difficult to manage. Just as the photographer has carefully arranged his blinds to give the lighting he wanted, with the sun shining, one of those lovely white clouds comes sailing along, and his whole scheme is upset, and he has to wait until "the clouds roll by," or else he starts again without the sun, and when he has re-arranged everything and is ready to make his exposure out shines the sun once more, and his work has to be begun over again. In my own studio I have some trouble from the same cause; the pitch of the studio roof is a little too flat, and before eleven o'clock the sun peeps over and shines on the sitter and I have to draw the white curtains; in a few minutes the sun may be obscured, and the light is then reduced too much. But as this is over by eleven o'clock it is not a serious inconvenience, as few sitters come before that hour. Now, however, with daylight saving the difficulty may last till twelve, and that's the only objection I have to summer time.

At the east end of the studio, by drawing a curtain aside I can get rather a nice effect with direct sunshine if I darken the rest of the studio, but it can be secured only when the sun shines, which, of course, it often doesn't do, and it is too far round in the afternoon. So I have given up trying to use it, because if I show any photographs with sunshine sitters want to be taken that way, and I cannot do it because it's a dull day, or perhaps too late in the afternoon. I also have a window on the south side, but I never use it, because the sunshine is so intermittent and uncertain.

Then a studio with a south light would be very difficult for all kinds of other work, besides portraiture, copying pictures, for instance, or photographing objects. The difficulty arises not only from the trouble in diffusing the direct rays of the sun, but chiefly from the frequent variations, as there are very few days in the year when we enjoy uninterrupted sunshine. Occasionally, as in 1911, we do get months of brilliant sunshine, but such years are like angels' visits. After all, we find that everyone who wants a good, even, steady light, the artist, the photographer, the engraver, and even engine fitter, gets a north light if he possibly can. If I were designing another photographer's studio I would sacrifice many things if, by so doing, I could get a north light.—Yours faithfully.

ATELIER.

STEREOSCOPIC RELIEF.

To the Editors.

Gentlemen,—With regard to Mr. R. W. Blakeley's opinion that dissimilar views for each eye are essential to a stereoscopic effect, I should like to tell him a little story.

In that blissful quarter of an hour between the times of being called and getting out of bed, I turned my face to the wall one morning and gazed blankly at the wall-paper, about three feet from my bed. Presently I was conscious that the wall-paper pattern had taken on a third dimension. It looked as though it was solid but made of transparent material. I could see into it for several inches. As usual, when anything apparently unnatural strikes one, I pulled myself together, raised my head from the pillow to see whether things in general were still as they should be. As I did so all the different items of the pattern scurried to other places as though they were ashamed of being caught out of bounds, and lo! everything was normal again. My head fell once more to the pillow, but, as it pressed to its former place the patterns scurried out again, and the stereoscopic effect was insistent until I finally moved.

I thought about this for several mornings, and played about with the effect, trying to find an explanation. Usually the pattern looked about two-thirds of its actual size and very near. Indeed, I put my hand out to touch it, but couldn't reach the wall until I had stretched a good way out of bed. (This proves something, surely, with regard to the relationship between stereoscopic vision and the sense of distance.) But once again the pattern looked enormous and comparatively far away. (This sounds very like D.T., but barring an occasional glass of wine with my lunch I am a teetotaller.) I have not been able to repeat this enormous effect. I expect it is in some way purely subjective. Of course, the actual size of the items of the pattern is a constant factor; so when they look near their size must look small, and vice versa.

The pattern is an old-fashioned textile design of lattice and a sprig-motive in each diamond. It is rather dark, but well marked. I found the explanation of the illusion by noticing that in the apparent solidity or depth of the images there was a vertical line of the diamond shapes that seemed more recessed than any others. It was always so whenever I got the effect in a period extending over some weeks. There was a paperhanger's "joint," only discernible upon close scrutiny, and having discovered this one morning I wondered how it would behave in my phantom-solidity view. I adjusted my head and got the illusion, but couldn't at first find the tiny suggestion of a white streak by which I recognised the joint—it was the thickness of the paper that had risen above the "butt-joint." After a while I found it *in duplicate!* One was each side of the depressed column of diamond-shapes. I knew then that the whole pattern was, in my eyesight, superimposed upon itself. There were two images. I checked this by looking at a chair and a table against the wall, and they had double images. The scurrying of the pattern to and fro (and somewhat up and down) was due to pressure by the pillow upon the eyeball. This I tested with my finger, and found that the slightest pressure on the edge of the bony orbit throws the eyes out of adjustment.

I was then satisfied that if two images precisely alike can be made to coincide a stereoscopic relief may result, and I further had discovered that those two images need not exist actually, so long as they exist in the dual sight. The combination in this case takes place somewhere between the two retinas and the brain. Will somebody please explain?

I should add that where the pillow partly obscured the pattern in one way, the other eye saw it within, or through the first eye's pillow image, and saw it in all the commonplaceness of normality.

Some of Mr. Blakeley's incorrigible friends who persist in saying "very nice," "very good," may be squinting into his stereoscope, and may thus superimpose the two images of the identical slides over which he wastes his "cursory breath."—Yours, etc.,

F. C. TILNEY.

THE P.C.U.K. AND PHOTOGRAPHIC RESEARCH.

To the Editors.

Gentlemen,—As an old "Conventioner," and one of the old school of workers, I am very pleased indeed to learn from your pages of the re-election of Mr. C. H. Bothamley as President of the forthcoming Bristol meeting, he being a true photographic scientist, and one who has done so much for the Convention in the past, more especially at the time when papers of scientific interest were the order of Convention week. As a holiday-making concern the Convention has been a success, and I understand that there was about £30 balance on the right side at the 1920 meeting, but its success and usefulness will be greater if some attention be given to photographic theory and practice, and Mr. Bothamley is the man to bring it about, he always dealing with scientific theories in a way the average worker can understand.

It does not appear to be generally known that the Convention has a fund—and a most jealously guarded one, too—for photographic research, and that the Council have power to make grants of money for the carrying out of special work. I have an idea that the last (and only?) time any of this money was granted was in 1897, Messrs. Haddon and Grundy's paper on "The Strength of Hypo-Solution and Time for Fixing Albumen Paper" being the outcome of it.

I think more publicity might be given to this matter of aid to research, and we might be told how much money is given, and to whom one must apply for particulars. The grant—if of respectable proportions—might be an inducement to some of our young and enthusiastic workers to investigate items of practice within their competency.—Yours faithfully,

GODFREY WILSON.

[The original idea was, we believe, to make a grant of only £5. We understand, however, that the matter was brought before the recent meeting of the Council, that it is to be considered by a sub-committee, and that an announcement concerning the grant may be expected in due course.—EDS. "B.J."]

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. H.—"Camera Work" was formerly published by Mr. Alfred Stieglitz, 1,111, Madison Avenue, New York, but its publication ceased some years ago.

H. W.—Ordinary unbleached sheeting is generally used, and this can be had up to 108 inches wide. Scene painters' canvas has been used, but is much more expensive.

S. A.—When using anhydrous sodium sulphite instead of the crystal, use half the quantity. As regards the soda carbonates, 10 parts of the crystal carbonate are equivalent, in alkaline strength, to about 4 parts of the anhydrous.

O. J.—The 4½-inch Wray is worth about £1: the 5 x 4 Wray, *f*/5.6, if of 6 inches focus, is worth about £2: the whole-plate Wray should be worth about £3. We do not know an "Auto" daylight enlarger of Houghton's under this name. If you mean simply a fixed-focus enlarging box it is worth, perhaps, about two-thirds its pre-war price.

F. A.—We remember the bromide paper in which the paper had a metal coating. If we remember rightly it was placed on the market here for a German firm by the Rotary Photographic Company, but it has not been on sale for many years. At the present time, so far as we know, there is nothing of this kind made, such results being very much more easily obtained by the carbon process, or by one of the transfer bromide papers, such as Kerotype, or Kodak Transferotype.

J. L.—(1) A good studio plate of about 400 H. and D. (2) Yes, but not at all easy to arrange the requisite lighting of the sitter and the background. (3) Prints are generally worked up to a fair extent. (4) Nothing better than the pyro-soda recommended by the makers of the plates. (5) If the camera will carry it, about the best lens for half-plate size is a portrait lens of about 10 inches or 12 inches focal length, but it is a big and expensive lens. (6) It would seem that your lens is simply an ordinary R.R. Impossible to say who made it. Many of them came from France.

N. E.—As published in the issue of the "Colour Photography" Supplement of March 5, 1920, where the patent specification is reprinted, "Bakelite" has been protected for the making of colour screen-plates by Max Wieland, 47, Bosestrasse, Tempelhof, Berlin. Of course, there have been scores of processes for making screen-plates of geometrical pattern patented within the last ten years or so. You will find particulars of all of them indexed under "Colour Photography" in the annual indexes to the "British Journal." So far as we know none of them are commercially used.

B. L.—We are afraid there is no satisfactory method of straightening an ebonite shutter which is warped. No doubt very great hot mechanical pressure would flatten the shutter, which could then be re-worked if necessary to fit the slide, but the game is scarcely worth the candle. We have used unblackened sheaths in the N. and G. changing boxes for many years without finding any drawbacks. In fact, unless the blackening is of an exceedingly tenacious kind, such as that used by the makers of oxidised lens mounts, we would much sooner be without it, as it is very liable to chip off and cause marks on the plates.

C. J.—The process is, of course, quite different from using the so-called ferrotype buttons or cards in a cannon camera. You have to make a negative, and then a print from it. There is nothing difficult at all in making the print, but making the negative is a little more difficult than making the direct positive as you have been doing with your cannon camera, and, of course, takes consideraby longer. Generally speaking, we think you could very easily learn to do it, but do not think it is a very good commercial proposition, because the process takes a longer time than people will wait. Cameras of this kind have come on the market every now and again, but never into general use.

S. B.—(1) You ought not to fit the diaphragm right in the front of the lens, since to do so introduces distortion. The cells must be a very close fit indeed if you cannot find room for a Waterhouse stop. If we were you we should send the lens to the Premier Optical Co., 63, Bolton Road, Stratford, E.15, who, if it is at all possible, could fit a Waterhouse stop. We do not know that a diaphragm cap is on the market. (2) So far as immunity from action of the developer is concerned lead is an excellent material for tanks. Though acid may be used in compounding separate stock solutions, it is neutralised in the working developer and has no effect. Even with an acid fixing bath, in which there is free acid, the action is very slight on lead, and lead-lined tanks can be satisfactorily used for this bath.

J. M.—We think it is a waste of money to buy an anastigmat of such a long focus as 14 inches for covering a half-plate. If you were to get a good Dallmeyer R.R. or Ross Symmetrical of this focal length you would pay a good deal less, and have a lens that was capable of just as good results, even when using panchromatics. The aperture would not be larger than *f*/8, but in nine cases out of ten you would have to stop down your anastigmat to that aperture, or smaller, in order to get depth of focus. We recommend you to get one or two lenses of this kind on approval from a firm of dealers in second-hand apparatus. The money you would save would enable you to buy a short-focus anastigmat, which we should think you will really need for jobs where you cannot get much space between the camera and the subject. As regards prices, we have recently published prices for commercial work suggested by the Edinburgh Society of Professional Photographers, which we think ought to be a reasonable guide to you. You might base your charge for taking a negative and supplying one print on these; further prints at, say, Raines's prices.

Contents.

SUMMARY

In the concluding part of his article on a comparison of development methods, Dr. B. T. J. Glover discusses particularly the respective merits and demerits of time and factorial development in relation to the making of negatives (from subjects of different ranges) suitable for different printing papers. He adds a few notes on the correction which could be applied in the way of intensification or reduction without interfering with the "correct" character of the negative resulting from exposure. (P. 195.)

Mr. E. J. Wall, in some notes on the history of certain processes, traces the collodion positive to Scott Archer, and Monckhoven's intensifier, in substantially its present form, to the French experimenter to Ad. Martin. Also, he finds the germ of self-toning paper in an article by Mr. John Spiller, published in the "Photographic News" in 1860. (P. 197.)

Precautions in manipulation, which may well be disregarded when plates of moderate speed are being handled, become important in the case of emulsions of the great sensitiveness now obtainable. We have some notes on the chief respects in which such care needs to be exercised in an article on page 194.

Entries for the forthcoming exhibition of the Professional Photographers' Association may be sent in a day or two later than previously announced, namely, until April 11. Pictorial exhibits are to be selected by Messrs. Angus Basil, Bertram Park, and R. N. Speaight; technical work, by Messrs. Alexander Corbett and H. A. St. George. (P. 206.)

Details of the construction of a folding reflex camera, the first fully finished model of which will be shown at the Photographic Fair, are contained in a recent patent specification. (P. 200.)

Methods of producing tint effects without the use of a tint-laying apparatus in the making of line blocks are described in a contribution to "Photo-Mechanical Notes." (P. 199.)

Strongly restrained development and the subsequent use of the iodine-cyanide reducer is a combination which will do much towards obtaining presentable results from stale plates. (P. 194.)

A caution in respect to the F. numbers on a shutter of the between-lens type may be necessary to those unfamiliar with the varying efficiency of such shutters, according to the size of the diaphragm opening. (P. 194.)

The old method of putting hand work on a sheet of ground glass bound up with the negative is one which has many a useful application at the present day. (P. 193.)

The advantage of thorough screening of the photographers' eyes when judging strong lighting in the studio is the subject of a paragraph on page 193.

EX CATHEDRA.

Judging the Lighting. When working in a brightly-lighted studio the operator is often deceived as to the effect of the lighting by the flood of light which enters his eyes and prevents him from appreciating the true value of the light which is falling upon the sitter. This is particularly the case when working against the light; the effect appears much flatter to the eye than it does to the lens, assuming that the latter is properly shaded. The remedy for this is obvious, although few workers seem to realise it. It is to shade the eyes as well as the lens, and for this purpose nothing is better than the old-fashioned canopy beneath which both the operator and sitter were situated. This fitting is rarely seen now, and the operator must rely upon the simpler plan of shading his eyes with his hands, as he does instinctively when looking at a sunlit view out of doors, all that is necessary being to cut any brightly-illuminated window, or electric lamp, out of the field of view. Where the size of the studio permits, the canopy is a boon to the operator, as not only does it supersede the focussing cloth, but allows of children and nervous sitters being taken without their knowledge. Several well-known American photographers, and on this side Mr. Marcus Adams, have seen the advantage of thus camouflaging the camera.

* *

Simple Local Control. A very simple method of controlling the density of negatives locally consists in the use of a sheet of ground glass of the same size as the negative placed glass to glass against the latter, and the two bound together with lantern-slide binding. The exposed ground side of the glass is then worked upon with pencil or stump where required. This idea may not be new to many, but is of considerable value in pictorial work, such as lightening tones and shadows, etc., in landscape or architectural work; and the use of glass has certain advantages over tissue paper or papier mineral secured to the glass side of the plate. This is especially so if the plate is to be printed by contact, the double thickness of the glasses assisting in making the hand-work less evident in the print. Any errors in manipulation may be rapidly removed from the ground glass with a damp cloth and the work done again immediately, which cannot be said of the former method, which only allows of rectification of mistakes by the application of a fresh sheet of paper. Care must be taken not to put too much work on the glass, and any hard outlines may be gradually softened off by gentle rubbing with a piece of chamois leather strained over one finger. When lightening shadows or controlling high-lights by this method the photographic image must always be visible in the negative when viewed against the light. When a sheet of glass has served its purpose it may be cleaned off and used again for another plate, and so the method is not expensive.

The slight grain in the glass may appear in the print, but not to any extent. In some specimens that we were recently shown it had quite an attractive effect in the picture.

* * *

Shutter Efficiency and Diaphragms. A point which is often overlooked by users of between-lens shutters is the difference of efficieney which arises from varying the aperture of the diaphragm. With shutters which open from and close to the centre, the full aperture of the lens is only available for a small proportion of the exposure. This is most marked in shutters of the Unicum type, where two circles move across each other, but even with those having a star-shaped opening it is considerable. It is thus obvious that the smaller the diaphragm aperture the greater is the efficient exposure. Thus, with such shutters the ordinary practice of doubling the exposure at each step on the iris scale will not give equal exposures, because a diaphragm aperture of *f*/16 is fully exposed for a longer time at any given shutter speed than one of *f*/8 would be at the same setting, therefore it would be safe to give rather less than the quadruple exposure which would be necessary with a focal-plane shutter or a cap. This variation, of course, differs with different types of shutter, but it is always worth considering when the question of the possibility of using a smaller aperture than the full opening arises.

* * *

The Development of Stale Plates. Although no one would willingly use plates which have deteriorated by age or careless storage, it is occasionally necessary to deal with such, either because no others are at hand or because exposed plates have suffered through a long journey in tropical climates. In such contingencies quite serviceable negatives may usually be obtained by disregarding the surface fog which usually appears at an early stage of development, and developing until no further action appears to take place. Fixing should be thorough, so that there is no risk of staining on any after-treatment that may be necessary. It may now be found that the images, although rather foggy, are capable of yielding a good print, but if this is not the case, the fog may be removed by treating with a reducer, the best form of which is the usual iodine and cyanide solution which does not alter the colour of the image, and which appears to have a tendency to dissolve the foggy veil before it attacks the true image. Pyro-soda, with a slight addition of bromide, is a suitable developer, but hydroquinone, either with a caustic alkali or a carbonate, is better, as it appears to give more contrast and at the same time minimises the veiling.

* * *

Panoramic Groups. Although a specially-designed camera, such as the Cirkut or Al Vista, is the most convenient for the production of groups whose width is great in proportion to their height, very satisfactory work can be done with an ordinary camera and a lens of fairly wide angle. For the sake of economy it is advisable to have plates cut to conform to the size of the print: in the case of a 12 x 10 camera a 15 x 12 plate will give two 12 x 7½ plates, and for 15 x 12 slides the plate may be cut lengthwise to give 15 x 6, or if this be too narrow an 18 x 15 would give 15 x 9. If the expense is not a consideration the full size plate may be used, or if more than one exposure be needed half the plate may be covered during each. One objection to wide angle groups is the broadening of the outer figures if the lens is of very short focal length, but such a lens need not be used if there is room, as there is generally, to take up a sufficiently-distant standpoint. In any case, this distortion may be minimised by arranging the group in a curve, as is recommended to users of the Cirkut. There is a tendency for the centre to receive more exposure than the ends, but if a full exposure be given this will not be apparent in the print.

THE HANDLING OF ULTRA-RAPID PLATES.

The speed of present-day plates has reached a point of which the most sanguine of the original experimenters never dreamed. Almost every week advances in this direction are advertised, and we can assert from practical tests that in most cases the makers' claims are well founded. A rapidity of 500 H and D is now looked upon as quite ordinary; some makers have gone far beyond this with isolated batches, but have not ventured to put them upon the market, owing to the difficulty of making such extremely sensitive emulsions upon a commercial scale. It appears, therefore, that we have by no means reached the limit, and that in the future we may be using plates which are as great an advance on those we are using as the latter are on the productions of the last century.

During the transition from wet collodion to gelatine emulsion, great stress was laid upon the necessity for extreme care in the handling of the new plates, which in the hands even of experienced workers often gave flat foggy negatives, and it may be said that the recent advances render a reiteration of such warnings desirable. It seems that in many cases it is overlooked that a plate which is exceedingly sensitive to light transmitted by the lens is equally sensitive to light which reaches it in other ways, and the result is a want of clearness and brilliancy, just the trouble experienced by the past generation.

From a considerable experience of the modern plates we are able to say that this is due in all cases to want of care or knowledge on the part of the operator, for it is as easy to produce dense high-lights, if needed, and clean shadows with a 500 H and D emulsion, as it is with one of ordinary, say, 100 H and D, provided proper precautions are taken. The first point to be observed is naturally the safety of the dark-room illuminant, and this is doubtful in many professional dark rooms. As a general rule, a very rapid plate takes much longer to develop than a moderately slow one, and if dish development be practised this means that the rapid emulsion is exposed to the red light for, say, twice the time that the slow one would be. The extra speed would probably permit of a fogging action, even in the same time, and with double time such fogging becomes pronounced. Added to this, the emulsion may be isochromatic, and this further tends in the same direction. It is extremely difficult, if not impossible, to produce a red light of any useful visibility to which such plates can be safely exposed for any considerable time, so that after installing as safe a light as possible, it is wise to keep its direct rays from falling upon the developing dish a moment longer than is necessary for inspection. This can be done easily by providing some screen behind which the dish can be placed during the greater part of the time. It should be noted that the fogging is more likely to occur before or during the early stage of development, so that plates should not be unnecessarily exposed while filling slides or before placing in the developer. A recent case of partial fog was traced to allowing plates to lie, overlapping each other, upon the bench while filling.

Diffused light in the camera, whether it arises from badly blacked bellows, shiny diaphragms or dusty or depolished lenses, has also a flattening effect upon the negative, which becomes more evident as the sensitive-

ness of the plate is increased. Omission to shade the lens effectively is still another error. Camera fog and dark-room fog can easily be distinguished by observing whether the edge protected by rebate of the slide is clear or not. An often unsuspected cause of fog with rapid plates is the penetration of light through the wood of the slide. We have seen slides left in sunlight in the studio for a quarter of an hour—quite long enough to cause mysterious markings.

Regarding a general weakness of the image, it is usually safe to attribute this to unsufficient development, due either to the use of a solution too weak in alkali or to too short a period of immersion. We cannot sufficiently emphasise the necessity for using the formula issued with any particular brand of plates if easy working is required. We recently found that the thin yellow images complained of by a correspondent were due to the use of a developer containing one-fourth the proportion of soda and one-half the pyro prescribed by the plate makers. This had worked admirably with a slower brand, but even in double the time failed to produce a brilliant image with the rapid emulsion.

The lighting of the sitter must also be considered. With a plate which has a tendency to give clear glass in the shadows, the lighting may be somewhat flat, yet the negatives will appear fairly bright, but with a plate which makes the most of all the light falling upon it, this flatness will be evident in the finished result. We do not, be it understood, advocate harsh lighting for rapid plates. The lighting should appear to the eye as it is desired to appear in the print; the plate can be trusted to do the rest.

Those who practise tank development will escape many of the pitfalls we have enumerated. All that is necessary is to give sufficient time to obtain the desired contrast, and not to expect perfect results from varying brands of plates by a uniform time of development. It is unsafe to judge density by the appearance of the image upon the back of the plate, as variations in the thickness of coating often lead to error.

A COMPARISON OF DEVELOPMENT METHODS.

(*Concluded from page* 183)

Time Development.

The knowledge that is required beforehand to enable the time of development required for some specific purpose to be calculated with precision is classified below:—

(*a*) The range of light-intensities in the subject.
(*b*) The development rate of the plate.
(*c*) The nature and concentration of the developer.
(*d*) The temperature at which development is conducted.
(*e*) The exposure range of the printing paper.

Every one of these factors contributes an effect upon the time of development. The only items which can be readily measured are the temperature of the developer and the exposure range of the printing paper. The measurements of the remainder present difficulties almost insuperable. It is most unfortunately true that the development rate of a plate varies from one make of plate to another, and *varies between different batches of the same plate*. In any one plate it becomes slower with the age of the plate. The concentration of the developer depends upon the degree of purity of the constituents, a matter beyond the photographer's control. With many developing reagents the amount of dissolved air in the water used affects the time of development, and this amount varies with different water supplies, and in the same water supply at different times. The effect of different temperatures does not only depnd upon th developer, but also depends upon the batch of plate in use, so that the temperature co-efficient of a developer is an attribute of both developer *and* plate. The range of light-intensities in any one subject has a visual range measurement and a photographic range measurement. The former measurement is appropriate when fully screened panchromatic plates are in use, and the latter when ordinary (non-colour-sensitive) plates are used. Partially screened panchromatic, orthochromatic and self-screened orthochromatic plates will view a subject range as one which is neither entirely visual nor entirely photographic. The list of disabilities has perhaps been sufficiently extended to show how far from being precise modern time development is.

The time and temperature tables published ignore the subject range, ignore the fact that the development rate of the plate changes from one batch to another, assume that the effect of temperature changes is always the same, give no information as to the printing process appropriate, and assume that the photographer can imitate the strength of the developer upon which the lines in the table were based. A short step in advance is made by the makers of panchromatic plates, who do calculate development times for each batch of plates and differentiate between subjects under the headings "portrait," "architecture," and "landscape," portrait standing for a long-range subject, architecture for a medium-range subject, and landscape for a short-range subject. The subject divisions are vague, and occasionally very misleading, for each of these subject categories can yield both short and long scale examples.

There can be but little doubt that modern time development is a crude approximation, and can only yield a precise result by happy chance. From the very nature of the problem of development, time development as at present practised must yield negatives of very different ranges, whose development errors need to be corrected in some manner subsequently.

Grotesque as negatives may be when developed by inspection by beginners, and advantageous as it may be to teach beginners to develop for an average time obtainable from a time and temperature table in order to keep the errors within reason, there can be but little doubt that a negative developed by an experienced photographer by inspection has as good a chance of turning out what is required as a negative which has been developed for a calculated time in the manner of present practice. Guesswork plays the major part in both methods. Practical photographers may not, and as a rule do not, know very much about the properties of the materials which they use, nor have they very much knowledge of the principles which govern their use, but they have a keen eye for spotting a good negative, which gives them what they want in a definite printing process, and the fact that many eminent photographers stick to development by inspection, and abhor a tank, shows how little there is in it. Of two methods equally bad, neither can be called the better.

Factorial Development.

The Watkins factorial method of development, when applied to the development of plates for the production of negatives, eliminates some of the disabilities of time development, could by elaboration be made to eliminate others, and introduces some which are peculiar to the factorial method.

The disabilities which are very satisfactorily eliminated are:—

(*a*) The variable rate of development of different plates and different batches of the same plate.

(*b*) Uncertainty due to the concentration of the developer.

(*c*) The effect of temperature on the time of development.

The disabilities which are introduced are:—

(*d*) The occasional inconstancy of the Watkins factor in the same developer.

(*e*) The influence of varying exposures upon the time of appearance of the image.

The remaining disabilities of pure time development were the range of the subject and its relationship to the exposure range of the printing paper. An elaboration of the factorial method might overcome this difficulty. The simplest case would be the development of a panchromatic plate factorially which has been *fully* screened during exposure.

The factorial development of panchromatic plates has now been made possible by the introduction of desensitising agents,* in which the plate can be bathed in darkness before development is commenced. To the fully screened panchromatic plate the range of the subject is what the eye can see, namely, the visual range. This can be measured in a simple manner, although so far as I know there is no simple instrument sold for this purpose. The relationship between the range of the subject measured and the exposure range of the printing paper (Table I.) can be expressed as the gamma or contrast to which the plate should be developed in the following simple manner:—

Suppose the subject range is 40 to 1, and the paper range 1—20. The negative gamma required is the logarithm of 20 divided by the logarithm of 40 $= \frac{1\cdot3}{1\cdot6} = \cdot8$. Development to a gamma of .8 gives the negative required. Similarly a 40 to 1 subject is to be depicted on a 1—100 paper such as platinum. The required negative gamma is $\frac{\log 100}{\log 40} = \frac{2\cdot0}{1\cdot6} = 1\cdot25$. In these two cases the same subject can be rendered upon soft gaslight paper and platinum paper in the same manner by printing from two negatives developed for different times to a gamma of .8 and 1.25 respectively. With any developer the factors could be worked out for gamma of different values, so that whatever be the relationship between the subject and the printing paper, the negative gamma required would have an appropriate Watkins factor. Factors for gamma .6, .8, 1.0, 1.2, 1.4. . . . 2.0 would cover the whole ground. The factors so provided should be worked out for an exposure which is the minimum correct exposure. Errors in exposure would upset them in practical use. It is quite likely, however, that so used, with fully screened panchromatic plates, the Watkins factorial method would yield results more nearly accurate than any other practical method of development.

For use with ordinary or partially screened colour sensitive plates this method of calculating the factor required is not a practical one. The visual range of the subject differs from the photographic range by an unknown and variable amount. I know of no simple manner of estimating it. And if with these ordinary and partially screened colour-sensitive plates we develop factorially to a factor which is a mere estimate, guessing the allowance for the subject and the printing paper, and making an approximate allowance from the standard Watkins factor originally published for most developers by Mr. Watkins, then we must recognise once more that development is an approximation based upon guesswork, and that the errors in the result are liable to be extremely large.

It seems to be apparent that, knowing the purpose of development and knowing the causes of inaccuracy of each system of development in vogue to-day, it is a logical deduction that they are about equally inefficient. The fact that the three systems continue to exist side by side, one system favoured by some photographers and another favoured by others, lends considerable support to the view expressed in this paper, namely, that they are more or less equal. There are some photographers who waste a good deal of their time wandering from one developer to another, and from one system of development to another in the hope of improvement. With few exceptions all developers are equal. Purity and price are the only factors which the practical photographer need consider, and he could, with advantage to his pocket, use the cheapest *pure* developing reagent on the market. And so far as choice of a developing system is concerned the main deciding factor is convenience. If the photographer has many negatives to develop, and it is necessary to get them done quickly, then by all means let him develop them in a tank, roughly guided by time and temperature. If, on the other hand, the photographer is experienced in developing plates by inspection, then by all means let him stick to that method. To the beginner I would suggest either the factorial method or the time and temperature method as the readiest way for an inexperienced man to emulate the mistakes of his experienced brother, and not make even greater ones. But as they are at present practised, the particular system of development followed simply does not matter.

The paper will have served its purpose if it succeeds in emphasising what are the characteristics in a negative which enables it to yield a print appropriate to the subject, and if it indicates how imperfect are the present means of obtaining a perfect negative for a specific purpose. It has for the most part been destructive in criticism. The few remaining paragraphs will indicate the means at the disposal of photographers for the remedy of errors which they cannot avoid in the development of negatives by present methods.

Compensation of Errors in the Development of Negatives.

There are two important ways of compensating for the lack of success in producing a negative of some definite range. They are as follows:—

(*a*) The choice of a printing paper whose exposure range *will* fit the negative.

(*b*) An alteration in the range of the negative by intensification or reduction.

Let it be supposed that the negative was designed to yield a print upon bromide paper. When printed, however, the print was flat. That would mean that the range of the negative was too short, through under-development, to enable it to call forth the full range of tones of bromide paper. Obviously a shorter range paper is required. Soft gaslight paper has a shorter exposure range, and vigorous gaslight paper has a still shorter exposure range. To one or other of these two printing papers the photographer must turn if he wants a good print from that negative. On the other hand, if the print on bromide paper were harsh it would indicate that the scale of the negative had been rendered too long by over-development for the exposure scale of bromide paper. Obviously a longer scale paper must be sought for in P.O.P., or carbon or platinum. One method of getting a good print out of every negative is to make use of the different characteristics of different printing papers, and having failed to so develop the negative that it fits a particular paper, make use of another paper that fits the negative. This is the practice of trade printers who are noted for their skill in producing good prints from negatives of widely different ranges. They chose an appropriate paper.

The other method (*b*) seeks to alter the range of the negative in order to make it fit the exposure range of some particular paper. Intensification lengthens the negative range in the manner that longer development would have done. Reduction shortens the negative range in the manner that shorter development of the negative would have done. The two terms intensification and reduction are unfortunate. They are usually thought to mean an increase or decrease in density. It does so happen that there is an increase or decrease in negative density, with intensification or reduction respectively. But the real object of both of them is to increase or decrease density in a differential manner so that the *range* of the negative is altered.

* Sold as "Desentitol" by Messrs. Ilford, Ltd.

An appropriate method of intensification to increase the negative range is the bichromate bleaching method followed by redevelopment with amidol (chromium intensification). An appropriate reduction method to decrease the negative range is the mixed ammonium persulphate and potassium permanganate method of N. C. Deck[1], subsequently modified by K. Huse and A. H. Nietz[2]. Neither process is under good control, and the amount by which the negative range is altered has to be guessed at. The guess becomes more accurate with experience.

By one or other of these methods (*a*) and (*b*), or an appropriate combination of both, it is possible to obtain a print of any nature from any negative, which has been given a normal exposure, and has not been badly fogged during development.

In the course of this paper no reference has been made to the differences which exist between various types of printing paper as to the truth throughout the scale of the tones that they depict. All printing papers are untruthful in their representation of the subject at both ends of the tone scale (white and black), and some are more so than others. The most truthful papers are those which possess a characteristic curve which more nearly approaches to a straight line throughout its course than is the case with the less truthful papers. In practical photography these differences are small, and the small extent to which the eye can appreciate them is shown by the fact that platinum paper, the most favoured of all papers, compares very unfavourably with some brands of vigorous gaslight paper. The chief point of *practical* importance is the one laid down in this paper, namely, that the scale of the negative and the paper must be properly related to one another. It may be stated with confidence that those photographers who obtain prints upon one type of paper which compare unfavourably with prints upon another type, are using a negative of a faulty range upon the paper with which they are dissatisfied. The fault is in the development of the negative, and is not a fault inherent in the printing paper. For all practical purposes, modern printing papers of every type are capable of giving precisely the same results as one another so far as multiplicity of tone and tone values are concerned. It is sound practice in printing to choose any paper whose exposure range will fit the range of the negative, thereby compensating any reasonable mistake in the time of development of the negative.

Modern photographic practice involves:—

(*a*) The production of a negative of uncertain range by one or other method of development.

(*b*) The choice of a printing paper to fit that negative range.

(*c*) The alteration of the negative range by intensification or reduction if necessary.

SOME HISTORICAL NOTES.

The following notes are called forth by those which appeared in the "B.J." of February 4, p. 62, and it would appear that Messrs. Sotheran may be correct in ascribing to Ad. Martin the origin of the collodion positive, as he read a note before the Académie des Sciences[1] which deals with this subject, and there is an interesting corroboration by Delamotte,[2] which confirms this:—

"Conversion of negatives into positives (124). A negative picture, prepared as indicated above, can be converted into a positive in various ways. That suggested by Sir John Herschel consists in smoking the glass on the collodion side Or the proof may be backed with any black substance, such as varnish, paper, velvet, etc. (125.) Dr. Diamond obtains the picture by the usual collodion process, and develops by protonitrate of iron The negative image being developed a mixture of hypo-sulphite of soda, which has undergone partial decomposition, and pyrogallic acid is poured over the plate, which is slightly warmed. Upon this the darkened parts are rendered brilliantly white by the formation of metallic silver. The picture, being backed up with black velvet, assumes the aspect of a fine Daguerreotype, without any of the disadvantages arising from the reflexion of light from the polished silver surface. (126.) Mr. Archer obtains this result by pouring a solution of bi-chloride of mercury over the proof; Mr. Fry, by the combined action of pyrogallic acid and proto-nitrate of iron. (127.) M. Marten's (sic) communication to the Academy of Sciences at Paris details the following method of operations for producing *positives* directly on a glass plate: Make a solution of gun-cotton in ether The gun-cotton is prepared by heating 2 parts of cotton wool with 50 parts of nitrate of potash and 100 parts of sulphuric acid. This, when well washed and dried, is soluble in a mixture of 10 volumes of ether and 1 volume of alcohol to which are added 15 grains of nitrate of silver, converted into the iodide by iodide of ammonium, and dissolved in 300 grains of alcohol. (128.) The plate of glass covered in the usual way with this substance is plunged before it becomes dry into a bath of

Nitrate of silver	..	...	...	8 parts.
Nitric acid	..	...	...	5 ,,
Distilled water	..	...	...	100 ,,

(129.) For developing it is plunged into a bath of sulphate of protoxide of iron, and carefully washed. The picture is now a *negative*, but on plunging it into a bath of the double cyanide of silver and potassium it immediately becomes *positive*. It must next be washed and dried. The cyanuret bath is composed of

Water	...	.	...	2 qts.
Cyanuret of potassium	...	.	...	375 grs.
Nitrate of silver	...	..	...	60 ,,

The pictures produced in this manner possess great brilliancy."

One must not, of course, take Delamotte's notes as chronologically correct, as obviously Archer's method should come first and he says: "The whitening process. The picture being thoroughly washed in plenty of water, after fixing with hypo-sulphite of soda is treated in the following manner. Prepare a saturated solution of bi-chloride of mercury in muriatic acid. Add one part of this solution to six of water. Pour a small quantity of it over the picture at one corner, and allow it to run evenly over the glass. It will be found immediately to deepen the tones of the picture considerably, and the positive image will almost disappear; presently, a peculiar whitening will come over it, and in a short time a beautifully delicate white picture will be brought out. The negative character of the drawing will be entirely destroyed, the white positive alone remaining. This picture, after being well washed and dried, can be varnished and preserved as a positive, but nevertheless, even after bleaching, it can be changed into a deep-toned negative, many shades darker than it was originally, by immersing it, after a thorough washing, into a weak solution of hypo-sulphite of soda, or a weak solution of ammonia. The white picture will vanish, and a

2. "Practice of Photography," London, 1853, pp. 78, 79.
3. "Manual of the Collodion Photographic Process," 1852, pp. 38, 39.

black negative will be the result. It is very singular that the picture can be changed from a white positive to a black negative, many times in succession, and very often with improvement. Thus, by the above process, a most perfect white positive or a deep black negative is produced, quite distinct from each other."

It is clear that Archer fully recognised the collodion positive, even although he did not recommend backing it up with a black surface. Ought not to Archer, therefore, be given the credit of the collodion positive?

R. Hunt[4] says: "(231.) The negative collodion image can be converted into a positive one by several methods, all of them, however, depending upon the conversion of the film of darkened silver into a layer of brilliantly-white metallic silver. The best method of doing this appears to be one of the following:—First, protosulphate of iron, 20 grains; distilled water, 2 fluid ozs.; nitric acid, 4 or 5 drops; or, 2nd, protonitrate of iron, obtained by decomposition of nitrate of barytes, with the protosulphate of iron; or, 3rdly, by the use of a mixture of the protosulphate of iron and pyrogallic acid. Either of these solutions is poured over the plate; and in a short time a clear metallic image is obtained, which, when backed up with a black velvet or a black varnish, is superior to the best effects of the Daguerrotype."

Eder,[5] when dealing with the production of collodion positives—"helle Bilder auf dunklem Grunde"—ascribes treatment of the negative with mercuric chloride to Bertsch,[6] and the backing with black paper to Bertsch and Le Gray,[7] but gives no authority for backing with black or violet velvet or linen, but ascribes to Brebisson[8] the credit of black varnish.

Hardwich[9] deals rather fully with the subject, as one would expect, and one must be content with the following short quotation:—"In a collodion positive the lights are formed by the bright surface of the reduced metal, and the shadows by a black background showing through the transparent portions of the plate." He deals with the various developers that can be used and the use of mercuric chloride for obtaining white images, but nowhere does he specifically mention actually backing the plate.

It should not be overlooked also that Fox Talbot and T. A. Malone obtained an English patent, 12906 of December 19, 1849, in which "a method of converting or changing negative photographic images into positive ones" was claimed.[10] "To produce the negative picture, a clean glass plate is covered with a film of albumen by pouring a solution of albumen over the glass, and drying it; the film is then iodised by exposure to the vapour of iodine, dipped into a nitrate of silver solution, placed in the camera, and treated with an aqueous solution of gallic acid, which develops the latent picture. To convert this picture into a positive picture, a solution of nitrate of silver is allowed to stand some time on the plate; the resulting picture is still negative if viewed by transmitted light, but, if viewed by reflected light, is positive. To view the positive image well, the glass should be placed upon a dark surface." This proves that the idea of backing a negative with a dark background was known in the old albumen days.

J. Urie[11] patented, in 1854, an improvement in photographic pictures, in which to give photographs on glass or other transparent plates, "the effect of standing out in high relief from the apparent surface, the back of the glass or the surface opposite to that on which the image is taken is coated with a black varnish or other pigment."

Monckhoven's Intensifier.

Probably everyone is familiar with this well-known intensifier in which a mixture of mercuric chloride and potassium bromide is used as the bleach, and a solution of potassio-cyanide of silver as the blackener, and probably it will always be known by the above title. It was recommended by Monckhoven in 1879[12], yet as a matter of history it should be recorded that potassio-cyanide of silver was suggested by Ad. Martin as early as 1854, and probably in the very pamphlet mentioned by Messrs. Sotheran, for Eder says,[13] when speaking of collodion transfers—"dunkle positive Collodionbilder auf hellem Grunde"—that the toning of the primary image may be effected with a neutral gold bath, with palladium chloride, with mercuric chloride followed by hypo and with mercuric chloride followed by a solution of potassium cyanide, or hypo, saturated with silver; and to this last method he appends the following footnote:—"This process was recommended by Ad. Martin, of Paris, for transparent pictures for the purpose of precipitating on the image surface, by double decomposition, powdery metallic silver, so that the drawing would become black: 100 parts water, 2.5 potassium cyanide, and 0.4 silver nitrate. (Ad. Martin, in a pamphlet on direct positives published by him soon after the discovery of the collodion process, Barreswil & Davanne, Phot. Chemie, 1863, p. 245.) This is probably from a German edition of their well-known *Chimie Photographique*, the first edition of which was published in Paris in 1854. Martin's paper was printed in the English journals,[14] and he says:—"The silver reduced by these means is white, and gives only grey shadows. But this white silver must be transformed into black silver, which takes place when we pour upon the image, after being developed and well washed, *but not fixed*, a saturated, but non-acid solution of bi-chloride of mercury: the reduced silver becomes black by precipitation of metallic mercury. The picture is then carefully washed, and a solution of cyanide of silver in cyanide of potassium is poured over the plate. This solution is obtained by dissolving 10 parts of cyanide of potassium in 100 parts of water, and pouring into the resulting liquid a solution of nitrate of silver of the strength of 10 per cent. until the precipitate of cyanide of silver, which is formed, ceases to be re-dissolved upon agitation; upon being filtered the solution is ready for use. We can replace the salt of silver by a copper salt, which gives the same results; the metallic copper thus precipitated is black, and gives to the picture a tone exactly like that given by silver. Hyposulphite of soda may be substituted for cyanide of potassium, and the solution prepared in the same way, either with silver or copper. Hyposulphite of soda, which has served for fixing negatives developed with pyrogallic acid, and whose action has become exhausted, gave very good results upon the addition of a salt of silver or copper."

It is interesting to note that this process of intensification is precisely the same as recommended by Burton,[15] except that the latter recommended the use of ammonium chloride instead of the potassium bromide, and this change is of minor importance.

The Invention of Self-Toning Paper.

In the issue of the "British Journal" for April 20, 1906, p. 319, Mr. D. Bachrach claimed the invention of this particular class of paper, and in the issue for October 9, 1908, p. 781, I pointed out that Ashman & Offord[16] had published in 1885 a series of papers on gelatine-chloride emulsions and the addition of auric chloride "for quickening the toning process considerably." I have since discovered what may, I think, be justly termed the true invention of the self-toning principle. Mr. John Spiller[17] described in an article entitled

12. "Bull. Belge," 1879, *6*, 178; "Phot. Korr.," 1879, *16*, 208; "Eder, Handbuch," 1905, *3*, 542.

"On the Action of Chloride of Gold upon Certain Salts of Silver," the formation of a gold-silver compound, to which he ascribes the formula (old notation) $AuO_3.4AgCl$; but we are not particularly concerned with this salt, rather with his statement that follows:—"After obtaining the foregoing results with gold, I tried these compounds on paper and in collodion for photographic purposes. For printing, it was necessary to submit the paper to a double treatment in sensitising it, and these operations—floating successively on chloride of gold and silver nitrate solutions—must be performed immediately before use, in order to escape the effects of spontaneous discolouration. Thus employed, I found the consumption of the precious metals was larger for the same ultimate result than by the established process; but there is one aspect of the case which I have repeatedly studied in the hope of eliciting a really practical method; I refer to the circumstances that upon matt paper chloride of silver may be produced with a slight excess of common salt, and in this state preserved for a long time in a perfectly dark place. When required for use in rapid printing, its surface may be "extra-sensitised" by floating upon a highly dilute solution of chloride of gold, and hanging up to dry. *The paper gives from the first very agreeable tints, which remain almost intact whilst in the fixing bath, so that no supplementary toning process seems to be required.*" The italics are mine.

This is such a clear statement of a self-toning paper that to Mr. Spiller must be ascribed the discovery of the same. In a leading article[19] attention is called to a process, described as "Hennah's," in which gold chloride was used with ammonium chloride as a salting agent, the prints being subsequently hot-ironed. This presumably refers to T. H. Hennah, who was the author of some works on the collodion process (see R. P. S. Library catalogue, 1907, 33), but I have been unable to trace this particular method to him in any English journal, through presumably he was an Englishman.

Gold chloride was also used in the Wothlytype process,[20] and presumably to alter the tone of the resultant prints, but this can hardly be called a self-toning paper.

E. J. Wall.

Photo-Mechanical Notes.

Tint Negatives and Positives.

Photo-engravers and lithographers are frequently asked to add a tint or tints to reproductions, but every firm cannot afford to rent or buy a tint-laying apparatus. The process worker, however, has at hand all the appliances for making tint plates; the only addition he will have to make are some special shaped stops, which can be cut out of cardboard. The openings of these stops are shown in figs. 1 to 6.

The negatives are printed on metal, and etched in the usual way, or, in the case of the lithographer, printed on litho metal, from which transfers can be taken. The light required is that reflected from white blotting-paper illuminated by the ordinary arc lamps, the glasses of which should be quite clean and the reflectors freshly whitened, so as to ensure even illumination of the reflecting surface. These tint negatives and positives are made as follows:—Focus the camera for copying same size, and then move back to about the position for copying half size, without altering the camera extension. Place the half-tone screen in the holder, the ruling selected depending upon the fineness or coarseness of the tint required. The following table will give the approximate screen distance and exposure for light reflected from a pair of 10-amp. enclosed arc lamps:—

Screen ruling.	Distance.	Exposure. Wet plate.	Process dry plate.
	mm.	min.	sec.
60	13	3	60
80	10	3	60
100	8	2½	50
120	6.5	2	45
150	5.5	2	40

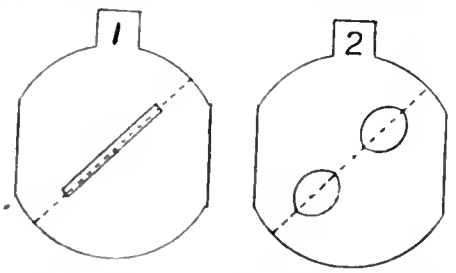
18. "B.J.," 1906, 53, 323.
19. Fr. Pat., 65,851, 1864; abst. "B.J.," 1865, 12, 97; "Phot. News," 1866, 10, 362; Eng. Pat., 2,347, 1864; U.S. Pat. 49,488, 1865; "Chem. Tech. Rep.," 1864, 3, II., 392. The use of gold chloride is not mentioned in the English patent.

Develop the dry plates in the usual hydroquinone-caustic for 1½ min., or if the temperature is below 62 deg. Fah., for 2 min. Stops 2 and 5 may require a shorter exposure than the others. The dotted lines shown in the illustrations represent the position of the screen-ruling in relation to the stop opening to obtain the effects described.

Stop 1 will give a straight-line tint when correctly exposed; if fully exposed, a thick line will be the result, which, when printed on the metal, yields a thin line. By making a positive from the negative and using for printing on the metal, a thick line is the result. Under-exposure is shown by the line being broken and lacking in density.

Stop 2.—A serrated line will be the result from using this stop. The print from the negative gives concave serrations; that from the positive gives convex.

Stop 3 will give a wavy-line tint, the thickness of which is

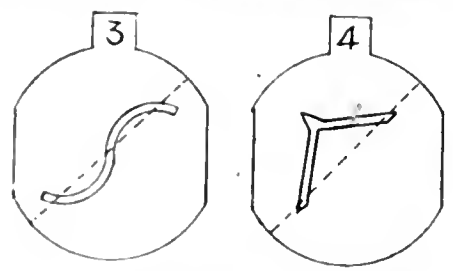


governed by the exposure. If under-exposed, the line will appear broken at the bend.

Stop 4 will reproduce a wavy effect one side and slightly so the other. Full exposure shows a fine joining up; thus the negative and positive will give different tints.

Stop 5 will give a copy of the screen, the print from the negative being a square dot, and from a positive, a screen tint.

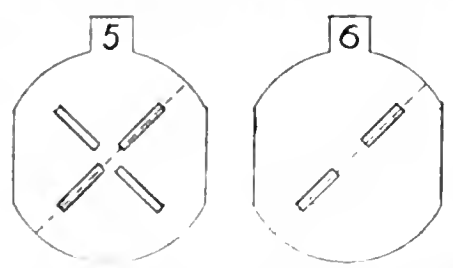
Stop 6.—A broken-line tint is the result of using this stop. A



small round dot tint can be made by racking the screen close to the sensitive plate, and then exposing through a small round stop (f/45 64). The negative will print a thick cross-line, having a small round opening; the positive, a small round dot.

By using a Metzograph screen a grained tint is secured; the screen must be brought up close to the plate, and a small round diaphragm used (f/64 or 90).

There are numerous other purposes for which these stops will prove useful—for instance, to emphasise a distinctive feature in a line advertisement. Make the usual line negative, after which



close and remove the dark-slide. Place the half-tone screen in the carrier, and replace the slide. Pin a sheet of white blotting-paper over the original, and expose through one of the stops already described, or through the Metzograph screen. The resulting line-negative will be broken up into tint, which is printed on the metal in the usual way. The portion or object to be thrown out in relief is then painted in solid with the usual etching ink,

or this can be done by a method of double printing, and then etched. The result is very striking.

Some effective and original half-tone reproductions can be made by using one of these stops for the shadows exposure. For the highlight exposure a stop must be cut of a similar shape, but having an opening double the width. An operator with an eye for originality and novelty, and who has time to experiment in this direction, will be surprised by the results obtained, and be amply rewarded for his trouble.

HALF-TONE SCREENS.—According to a patent specification, No. 156,713, open to inspection but not yet accepted, of Herbst and Illig, a half-tone screen is made by forming depressions in one of the surfaces of a plate and filling the depressions with an opaque material leaving a net of transparent lines crossing each other at uniform angles and flush with the opaque fields. Three methods of making the recesses are described by photographically or mechanically producing lines on a plate which will resist an etching solution, etching the recesses, filling them up with opaque material and finally clearing the surface of the plate.

NEGATIVES FOR OFFSET.—A recent patent specification, No. 156,692, filed by the Ullmann Gesellschaft of Zwickau, Germany, but not yet accepted, describes a process for obtaining negatives or transparencies which can be used either for offset printing methods or for making ordinary litho or rotary zinc printing surfaces A bichromated colloid negative is made on a surface from which it can be stripped and before stripping is coated with a gelatine solution forming an upper film. To produce the bichromated films two glass plates are secured together and coated at the edges with a rubber film margin or border. The combined plates are dipped in a solution of wax in carbon tetrachloride to obtain a thin wax film, and after drying into a 3 per cent. collodion bath containing a few drops of castor oil. The plates are separated, coated very thinly with bichromated colloid, and after exposure and drying the additional gelatine applied. The negatives may be retouched before stripping

THE ENSIGN HANDBOOK.—The little catalogue of 320 pages just issued by Messrs. Houghtons, Ltd., is really more than a price list of photographic requisites, for it includes ten chapters, occupying nearly 100 pages, written by Messrs. W. L. F. Wastell and Percy G. R. Wright, which provide an excellent and very readable introduction to the practice of amateur photography. Moreover, these text pages contain a glossary of photographic terms, the very simple explanations of which will stand many a beginner in good stead in the process of first making himself acquainted with the technicalities of photographic apparatus. The "Handbook" is supplied at the price of 6d., post free 9d.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, March 21 to 24:—

PHOTO-ELECTRIC CELLS.—No. 8,944 Photo-electric cells. T. W. Case.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FOLDING REFLEX CAMERAS.—No. 158,601. (September 26, 1919).—The reflex camera is provided with a sliding front which carries a focussing lens tube and is adapted to slide on to and off a hinged tail-board out of and into the camera casing, the sliding front being held rigid in the extended position by the tail-board and by a hinged focussing screen, in conjunction with the usual trellis connection, the sliding front being connected to the camera casing by flexible material surmounted by a flexible hood. The arrangement is such that when the camera is collapsed, the focussing screen and usual hinged mirror are folded behind, and the hood is folded in front of the sliding front, the hood having plates which with the hinged tail-board close the camera casing.

In order to facilitate rapid collapse of the camera the sliding front has a catch for engaging with the focussing screen when the camera is extended and the screen is in the usual horizontal position, the catch being released by a finger piece on the front of the sliding front so as to allow the focussing screen to fall.

A comparatively shallow main body 1 receives a sensitive plate or film, and carries the shutter and its mechanism. It is connected by flexible material 2 to a sliding front 3, so forming the dark chamber 4. The dark chamber 4 opens at the top into a focussing hood 5, which is preferably formed in one with the material 2 of the dark chamber. The side walls 6 and 7 and base 8 of the main body 1 are extended, and a tail-board 9 is hinged at 10 to the extended base 8, to permit inward and outward sliding movement of the sliding front 3, which movement is guided by guides 11 on the tail-board 9. The extended side walls 6, 7, of the main body 1 serve to house the sliding front 3 in the extreme inward position, that is to say, when the camera is folded or collapsed, as shown in fig. 3.

The guides 11 on the tail-board are formed at their inward ends into sector-shaped plates 12, having inturned edges 13.

These edges 13 are adapted to engage with the inturned edges 14 and 15 of the sides 6 and 7 of the main body 1, thus preventing the dropping of the tail-board 9 below a horizontal position.

A frame 17 carrying a mirror 18, and a frame 19 carrying a focussing screen 20, are mounted on spindles 21 and 22, carried

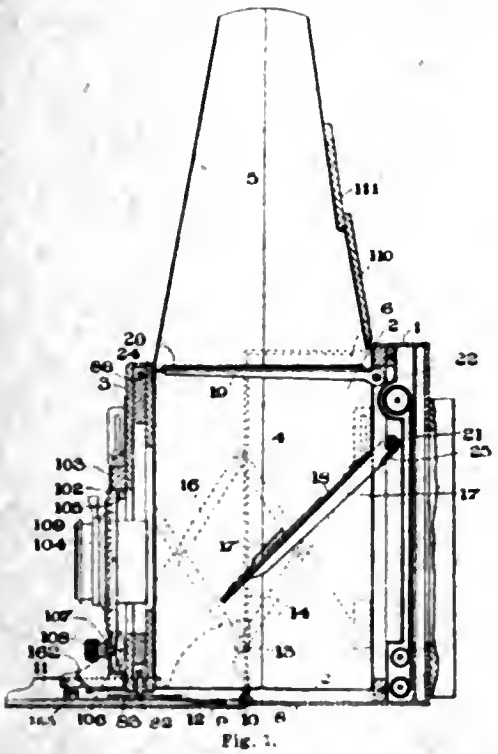

Fig. 1.

in the main camera body 1. The spindle 21 has a knob 90 outside the camera casing. The pivoting axis of the mirror frame is behind and below that of the frame carrying the focussing screen, so that when the mirror and screen are not required for

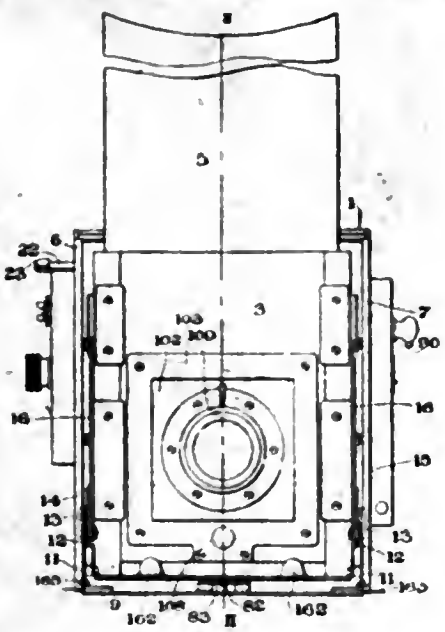

Fig 2.

use, that is in the folded position of the camera, the two frames depend vertically from their pivoting spindles, so that the screen lies over the mirror, as illustrated in fig. 3. Light plate springs 17¹ are provided on the mirror frame 17 to prevent the screen frame 19 damaging the mirror 18 when the camera is being collapsed. Alternatively, these springs may be fitted in the ground glass screen frame 19, and stop pins may be provided on the frame to hold the screen a definite distance from the mirror after the springs have cushioned the blow and have yielded.

When the camera is opened, the frame 19, carrying the screen 20, is moved about its axis by any suitable means, such as an external winged nut 23 secured to the pivoting axle 22, so that it extends over the opening between the dark chamber 4 and focussing hood 5, as shown in fig. 2, and is automatically retained in this position by a suitable catch 24 carried by the sliding front 3. The screen thus forms a tie between the main body 1 of the camera and the front or sliding plate 3, in this way ensuring rigidity of the camera in the extended position.

When the front plate 3 of the camera is brought forward into the extended position, a pin 82, projecting from its under side, comes into engagement with a slot in the spring catch 83, secured to the hinged tail-board 9 as shown in figs. 1 and 2. This engagement of the sliding front with the tail-board assists the focussing screen in holding the front rigid. The pin 82, as shown in fig. 4, is connected to the catch 24 through the medium of the pivoted lever 84, rod 85, and second pivoted lever 86. The rod 85, at the end in contact with the lever 86, is sloped or bevelled as shown in fig. 5, so that when the pin 82 is pulled down by pressure on the spring catch 83, and the rod rises, the bevelled end acts on the end of the lever 86, oscillating it so as to bring the catch 24 within the sliding front 3, thus releasing the frame 19 carrying the focussing screen 20.

When the focussing screen 20 is moved into the horizontal

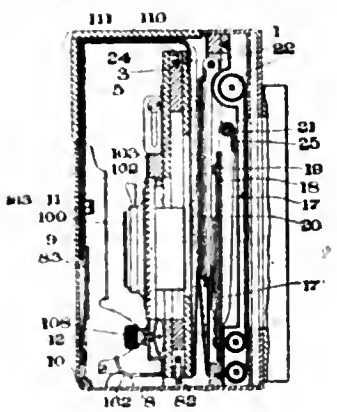

Fig. 3.

position as described, the mirror frame 17, carrying the mirror 18, is moved automatically about its pivotal axis by means of a spring 25 in the same direction as that of the focussing screen, until it reaches a position at which it is at an angle of 45 deg. to the horizontal axis of the lens, whereupon further movement is prevented by suitable means.

The lens plate 102, carrying a lens 109 of known type, is slidably carried by the sliding front 3.

The lens plate 102 is supported by a frame 103, so as to be capable of slight pivotal movement as indicated in fig. 2. The plate 102 is adapted to be moved about its pivotal axis 104, against the action of a spring 105, by means of a cam 106, adapted to bear on the rear of the plate 102 at or near to its base. The cam 106 consists of a disc fixed at an angle on a rotatable rod 107, arranged longitudinally of the camera and provided with a milled head 108 to facilitate operation.

Assuming that the camera be in its folded condition, as shown in fig. 3, and that it is desired to use the camera, it is first extended by pressing in and releasing the catches 163, folding down the tail-board 9, raising the hood 5, and drawing forward the front plate 3 by finger pieces or draw lugs 162 until the catch 82 engages within the spring catch 83. The wing nut 23 is then rotated to bring the focussing screen 20 horizontal. The parts including the mirror 18 then assume the positions indicated in fig. 2, the mirror being held at an angle of 45 deg. by a movable stop. The operator can then focus a view in the screen 20, having previously set and wound the shutter. He

can then make an exposure by releasing the mirror, which rises under the action of the spring 25, the mirror previously to the exposure assuming a horizontal position and effecting a light-tight closure beneath the focussing screen, as well as automatically releasing the roller-blind shutter.

In closing or collapsing the camera the catch 24, retaining the focussing screen 20 in the horizontal position, is released by pressure on the spring finger piece 83 on the tail-board 9. The focussing screen 20 then falls and carries with it the mirror 18 and frame 17 to the vertical position, as shown in fig. 3. The hood 5 is folded down over the lens and is covered in such

Fig. 6.

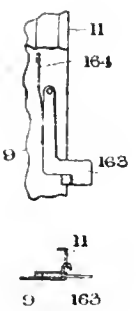

Fig. 7

Fig. 5.

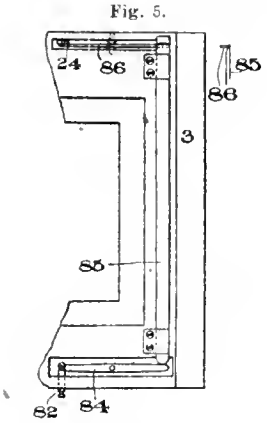

Fig. 4.

position by suitable closing or reinforcing plates 110, 111, so that in the collapsed position one plate, 110, extends along the top of the camera body 1 to the turned-over edge of the hood 5, while the other plate, 111, folds over this edge, a complete closure being effected by moving the tail-board 9 into the vertical position so that its front edge meets the free edge of the plate 111, and the catches 162 engage with the inturned edges of the casing 6.—Percy George Mason and Newman and Guardia, Ltd., both of 17-18, Rathbone Place, London, W.1.

The following complete specifications are open to public inspection before acceptance:—

Dye Process.—No. 160,137. Process for treating and dyeing photographic images and products obtained thereby. W. van D. Kelley.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Universum.—No. 382,665. Sensitised films for photography. Universum-Film Aktiengesellschaft, Unter den Linden, 56, Berlin, Germany, manufacturers. March 25, 1918

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

Ossal.—No. 374,868. Irridiating or lighting-up screens for Röntgen-ray work, being for surgical or curative purposes. Chemische Fabrik von Heyden Aktiengesellschaft, 57, Leipziger-strasse, Dresden, Saxony.

Correction.—In the note "Soda Carbonate and the Watkins Factor," in our issue of March 25, there are two literal errors which may lead to undesirable confusion unless corrected. In column 1, p. 168, 7th line from the bottom, the word *with* should begin a new sentence. In column 2, p. 168, in the table of factors, No. (2) should be 6.5 and not 65.

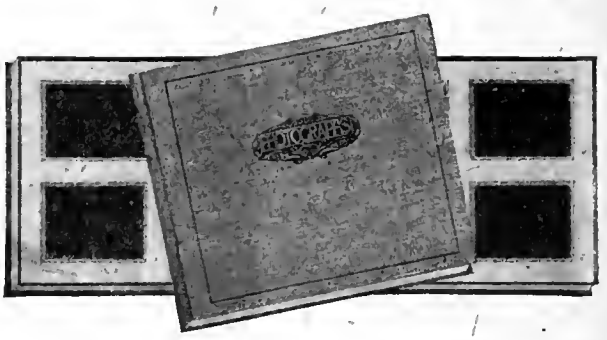
New Materials.

Extra Hard Bromide Paper. Made by Criterion, Ltd., Stechford, Birmingham.

Both for contact printing and enlarging a very considerable demand has sprung up of late years for a development paper which yields results of satisfactory contrast from negatives of poor quality in this respect. This demand no doubt chiefly arises in connection with the printing and enlarging of amateurs' film negatives, in dealing with which the printer must take things as he finds them, and very often has to work from very poor material. While gaslight papers may be readily used for such negatives by increasing the power of the light in the printing box, it is not so commercial an expedient to employ them for the making of enlargements. Therefore, "photo-finishers," and no doubt many others, will welcome this variety of bromide paper yielding the contrast of a gaslight paper, and at the same time permitting of the use of illuminants in the enlarging lantern such as are ordinarily employed for use with bromide paper. The Criterion "Extra Hard" is a bromide paper, we find, which marks the makers' long experience in the manufacture of such material. It works exceedingly cleanly, giving prints of good colour and entire freedom from stain, and, like other Criterion development papers, is specially manufactured for freedom from stress markings. It is made in a whole range of surfaces—glossy, platino-matt, silky (semi-matt), rough matt, canvas and cream crayon, and is obtainable also of postcard thickness.

Albums for Photographs. Made by Bartons (Birmingham), Ltd., Cosway Works, Finch Road, Handsworth, Birmingham.

For artistic excellence the productions of Messrs. Bartons in mounts and albums are second to none. Some specimens of their latest styles in albums of various descriptions, which they send to us, form still another confirmation of the high opinion we have of their goods. A most artistic 28-page list describes and illustrates the many styles. These latter include slip-in, paste-on and loose-leaf albums, made up in every case from mounting papers and boards of extremely pleasing neutral colours and agreeable textures, and enclosed within covers of choice design. The "Astor" is one of the slip-in albums which we illustrate. It is bound in art cloth, stiff boards, with a title and border printed in a colour to match the cloth. It is made in brown and grey, for either 48 or 96 prints, in the one case with two spaces per page; in the other with four on a page. This album is issued in six sizes, for prints from vest-pocket to post-card size, at prices which range from 4s. 9d. to 14s. each. Another style of slip-in album is the "Happy Recollections,"



in which covering leaves with cut-out openings allow of the insertion of prints of various sizes from No. 1 F.P.K. to post-card. Prices from 7s. to 12s. 6d.

The paste-on albums include some very choice examples, most of which are of the loose-leaf pattern, the flexible mounting sheets being held within the covers by a stout silk cord. The "Portman" is an album of this kind, containing 24 leaves, made in five sizes, from 6½ × 5 to 16 × 12 inches, at prices from 4s. 6d. to 20s. each. There are also some cheaper patterns, and a series of very stylish albums of the same loose-leaf pattern, in which the leaves are of black linen-texture flexible board. These are the "Cemiri," "Negro," and "Nocturne." Among the albums in which the mounts are fixed we should refer to the "Reynolds," of 24 linen-grained flexible leaves, with covers of grained calf leather with padded sides. This and others of a similar description make

ideal albums for the reception of prints on a photographer's reception table, or for holding collections of prints brought together for a customer.

BARNET PROCESS AND SUPER-SPEED ORTHO PLATES.—Messrs. Elliott & Sons, Barnet, Herts., have recently added to their series of plates one for line and half-tone negative-making, which we are satisfied will meet with favour from photo-engravers. The plate is of greater speed—about 75 H and D—than the average photo-mechanical plate, yet is of extremely fine grain and density-giving power. Its very sharp rendering of fine lines with the usual hydroquinone-caustic developer convinces us of its ability to yield screen negatives of the fine definition in the dots required by the photo-engraver. The Barnet Super-Speed Ortho plate has been lately improved in speed, with the result of further emphasising its qualities as an ultra-rapid colour-sensitive emulsion plate of the type which has steadily grown in popularity of late for studio portraiture.

MATCHLESS PAPER.—A departure from the existing emulsion methods of coating has been made in the introduction of this paper, which, in the absence of a gelatine or collodion coating, is akin to the plain papers in vogue many years ago.

The new paper, which is supplied by the Imperial Dry-Plate Co., is, of course, of the print-out class, although more sensitive than ordinary P.O.P. It yields a series of excellent warm tones simply by fixing in a hypo. bath, or may be toned with gold, either in a separate or combined bath, for tones ranging from warm sepia to purple. The range of tones is, in fact, very much greater than it is possible to get on any emulsion P.O.P. of the ordinary or self-toning kind. This fact, added to the retention of the natural surface and texture of the paper by the use of a sensitising solution as distinguished from an emulsion coating, renders the paper an altogether distinctive material, and one which will appeal particularly to the pictorial portrait or landscape photographer.

The manipulation of the paper is exceedingly simple. It differs from that of ordinary P.O.P. only in requiring a negative of somewhat strong contrast and a fairly considerable degree of over-printing. For warm tones, the prints are first washed in several changes of water and then fixed in a bath containing 4 ozs. of hypo. to 16 ozs. of water. A bath of about half this strength yields prints of a reddish-brown tone. For gold toning, the ordinary sulphocyanide bath may be used, or the bicarbonate bath familiar to those who used the once-popular albumenised paper. The combined toning and fixing bath is also suitable. By any of these gold-toning methods it is easy to secure exceedingly fine tones with a very small expenditure of gold.

The absence of an emulsion coating likewise makes itself evident in the readiness with which the prints can be blotted off and left to dry between blotters or dried by artificial heat. The paper is made in four grades, that is to say, white and buff, in each case of single and double weight. It is issued in all the regular English and centimetre sizes, and in sheets of 24½ × 17 inches, or 50 × 60 cm. In the cut sizes the price may be judged on the basis of 19 quarter-plate pieces in a packet priced at 1s. 3d. Twelve of the large sheets cost 22s. English size, and 25s centimetre size. These prices are for the single weight paper; double weight, 20 per cent. extra.

Commercial & Legal Intelligence.

NEW COMPANIES.

POMPEY, LTD.—This private company was registered on March 21 with a capital of £100 in 1,000 ordinary shares of 1s. each and 50 preference shares of £1 each. Object: To carry on the business of photographic dealers and picture framers, etc. The permanent directors are: C. H. Sheffield, The Cottage, Langston, near Havant (director Sheffield's Studios, Ltd. and Portsmouth Photo Co. Ltd.); Mrs. Minnie Sheffield, The Cottage, Langston, near Havant (director Portsmouth Photo Co., Ltd.)

New Apparatus.

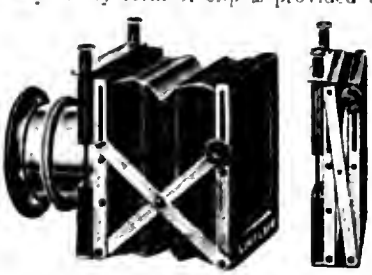
The Goodrick Electric Dry-Mounting Fixing Iron. Made by J. Goodrick and Sons, 52, Hare Street, Halifax.

SINCE the introduction, a few months ago, of a gas-heated fixing iron for dry-mounting, the very practical usefulness of the appliance has been shown by the requests made to the maker for a similar article, but utilising electric current as the source of heat. Mr. Goodrick has therefore now introduced a fixing iron which is even more handy in use than the earlier gas model. It is a hand-piece of 11 inches length, exceedingly well made in brass, and provided with an insulating wooden handle. The electrical heater is brought into operation simply by inserting the plug attached to the cable

into an ordinary lamp holder, and the fixing irons are made so that at any voltage from 100 to 250 the metal head which is applied to the tissue is kept at a temperature from 180 deg. F. to about 210 deg. F. This temperature is reached within about five minutes, after which the iron automatically keeps at the required heat without attention. The consumption of current is very small, about 1-16th of a unit per hour, and certainly the professional dry-mounter could wish for no cleaner or more convenient method of rapidly affixing the tissues to the prints. The fixing iron is supplied complete with a stand at the price of 25s., and may be obtained also from the distributing agents, Messrs. John J. Griffin and Sons, Kingsway, London, W.C.2. The voltage on which it is to be used should be stated when ordering.

Lens Hoods and Screen-Holders. Made by James A. Sinclair and Co., Ltd., 43, Haymarket, London, S.W.1.

IN their latest model of lens hood, that most indispensable accessory for outdoor photography, Messrs. Sinclair have made two improvements which greatly add to the usefulness of the appliance. The hood is fitted to the lens by means of a pair of adjustable grips controlled by the two milled heads shown to the left of the drawing. This allows of one hood being employed with lenses of various sizes. Also, a very handy form of clip is provided within the hood

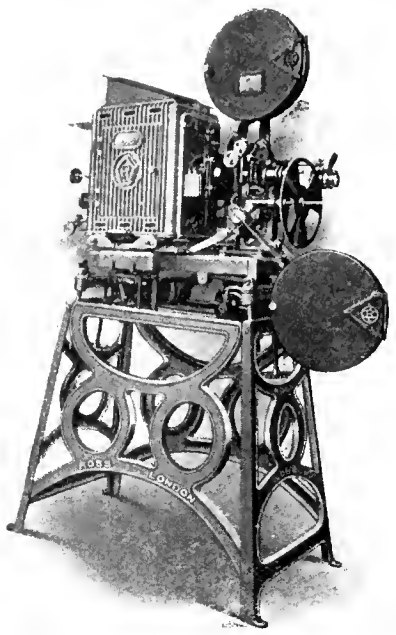


for holding a circular light filter in position. A light-filter can thus again serve several lenses. A pair of crossed struts, shown in the drawing, allows of the hood being adjusted to the most efficient extension, according to the angle of view of the lens. The hoods are supplied in three sizes for lenses from 1 to 1½ inches diameter, 1½ to 2 inches, and 2 to 2½ inches, at the respective prices of 25s., 30s., and 35s. K1, K2, or K3 screen to fit costs 5s. 9d., 7s. 6d., or 9s. 6d.

The Ross Cinematograph Projector. Made by Ross, Ltd., 3, North Side, Clapham Common, London, S.W.4.

LENS-MAKING being more than half precision mechanical work, it is not surprising that Messrs. Ross should turn to the manufacture of a cinematograph projector as a fitting sphere for the application of their many years' experience in the production of optical instruments of the highest class for the Admiralty and other services. In doing so, they have created a machine worthy of their name, which is saying a good deal, and embodying important and valuable improvements in mechanism for the showing of cinema films. Several columns of this journal might be filled in an adequate description of the features, chiefly mechanical, which are the outcome of the expert engineering knowledge applied to the design of the projector. It must suffice to say that this has been directed

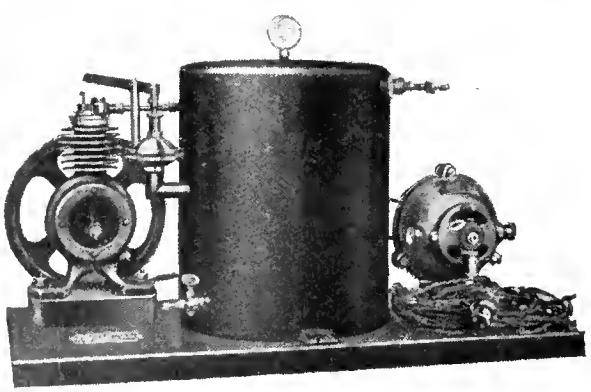
to obtaining (1) a better result—that is to say, greater steadiness, absence of flicker, reduced current consumption, and elimination of fire risks; and (2) the means of making good within a few minutes



any accidental derangement of mechanism which, under current cinema conditions, is subjected to incessant hard wear. The first of these aims has been realised in the highest degree by the choice of special types of gear, hardened metals, and most accurate machine surfacing, regardless of cost. The optical system, condenser and objective, has been computed for the single purpose of perfect projection, and to this end also the cover and flicker blades of the shutter consist of a coloured gelatine film, which eliminates intervals of total darkness in the projection cycle, thus reducing one physiological cause of flicker, and at the same time increasing the brightness of the projected image. The safeguard against breakdown is provided by interchangeability of parts of the mechanism exposed to the severest wear. Each of these latter is a complete unit, which can be taken out whole and replaced by a spare in a minute or two, for any readjustment of the removed part. The whole machine has been made as good as money and optical and mechanical skill can make it, and the remarkably perfect steadiness and regularity of the projections testify to the success which has attended its design. The price is £150.

Aerograph Studio Air Compressor. Made by the Aerograph Co., Ltd., 43, Holborn Viaduct, London, E.C.1.

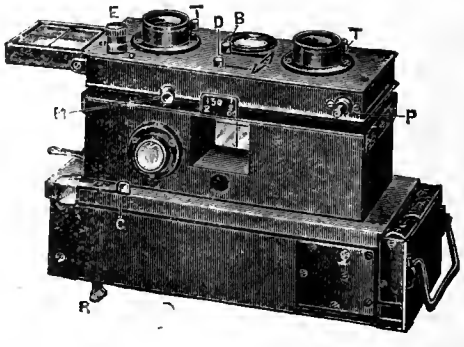
In this new piece of apparatus the makers have designed an air compressor specially for the use of an Aerograph hand-piece of their A pattern. The air compression is obtained from a small pump



operated by an electric motor of one-tenth horse-power, which can be run from an ordinary electric lamp fitting, and is extremely silent in working. The consumption of current is less than that of a 16 c.p. lamp, and the compressor is fitted with an automatic valve-release, which eliminates excessive consumption of electric current, and, at the same time, maintains uniform pressure of any required degree up to 40 lbs. per square inch. The whole apparatus is exceedingly compact, measuring 24 by 12 by 16 inches, and weighs only 50 lbs. It is a most excellent accessory for the regular use of the air-brush.

The Ontoscope All-Metal Stereoscopic Camera. Sold by the London Camera Exchange, 2, Poultry, Cheapside, London, E.C.2.

This is a French camera for the 45 × 107 mm. plates which have achieved such popularity of late years. In taking it up as a specialty of theirs, Messrs. Robbins, Manistre & Co. (The London Camera Exchange) draw special attention to several distinctive features of it. One of these is its rising front of 1 cm. movement, often a valuable aid in dealing with architectural subjects. Another is the lever focussing movement providing for the focussing of objects up to 3 ft. from the camera. A third feature is the shutter, which is provided with a range of speeds from 1 sec up to a marked 1-250th, which is found by tests to be a real 1-200th, quite fast enough for all ordinary work. Another feature is that the magazine, holding 12 plates, is fitted with a curtain metal shutter worked from behind and undetachable so that there is no loose sheath which may be mislaid. In other respects the camera is well equipped, *e.g.*, with a sunk finder and a direct-vision finder and spirit level, and is of fine mechanical workmanship. Fitted with a pair of *f*/4.5 "Stellor" anastigmats the price is £41; with two *f*/4.5 Krauss "Tessars," £45. The camera is also made in a model without the rising front and the focussing adjustment, the



respective prices being £37 and £43. It is also supplied with *f*/6.3 "Saphyr" lenses, price £30 15s., without rising front or focussing movement. These prices include leather sling case.

The Kershaw Soft-Focus Lens. Sold by Marion and Co.' Soho Square, London, W.

This is a quite new British objective for portrait photographers, and one which we think will speedily find favour among those able to see the business value of the soft-focus portrait. At its full aperture of *f*/5.6 it gives a most pleasing and distinctive kind of diffused definition, somewhat greater in degree than that given by, say, a Petzval adjusted for soft focus, but nevertheless agreeable in its softening of outlines and general modelling. As the lens is stopped down the definition is sharpened so that the degree of soft-focus is very readily controlled. At the expense of speed, certainly; but with plates of present-day sensitiveness, the portrait photographer can work with apertures such as *f*/8 and *f*/11, which a few years ago he would have considered impracticable. Apparently the softness of focus is obtained by a mixture of spherical and chromatic aberration, as was the case with the "anachromats," with which Captain Puyn years ago produced the delightful results which first drew attention to the merits of the soft-focus lens in portraiture. The work of the Kershaw lens is of the same kind, and those who remember the French portraits will accept the comparison as a very real commendation. It follows that the lens has a chemical focus, but we find that very little allowance requires to be made for it; if focus is taken on the part of the subject nearer to the lens, the distinctive quality is obtained in the planes situated immediately behind. The "single" construction of the lens is no doubt one reason for the brilliance of the soft image produced by it. The lens with which these trials have been made had a focal length of 12½ inches, and is supplied at the price of £9 9s.

Cinematograph Studio Spot-light Arc Lamps.— The Westminster Engineering Co., Victoria Road, Willesden Junction, London, N.W.10, whose enclosed arc lamps have been the stand-by of hosts of portrait photographers for many years past, have recently added to their series of these lamps for cinematograph studio use a model specially designed and mounted for spot-light effects. The lamp is of the long burning, semi-enclosed type, giving a soft actinic light. It is supplied in a lantern fitted with a 6-inch condenser, and may be obtained on one or other of two stands, one a lofty ladder erection, accommodating both the operator and the lamp at heights ranging from 9 to 15 ft., and the other of telescope tube pattern, extending to 8 ft. in height. Comparative tests have shown the very great efficiency of the enclosed and semi-enclosed arc lamps in the making of cinematograph negatives. Those interested should obtain from the Westminster Engineering Company a report by Mr. H. M. Lomas of tests carried out by him.

Half-Watt Fittings.—The General Electric Co., 67, Queen Victoria Street, London, E.C.4. have recently introduced two new studio fittings for the high-power half-watt lamp. These are counterbalanced holders for the lamp (within an angled reflector), adapted in one case for attachment to the ceiling or beam of a studio, and in the other, which is a movable standard, for use anywhere in the studio. The former model consists of a pendant, which allows of the lamp being raised or lowered, and also of the reflector being rotated on a vertical axis, so that the light is fully under control. If required, a small brass cradle can be fitted so that the whole pendant may be moved on a rail erected across the studio. In the standard pattern, the lamp and reflector are attached to a balanced arm, and can be raised or lowered at a touch between the limits of 3 ft. and 8 ft. from the floor. The arm itself also revolves on the head of the standard, and thus provides a wide range of movement without shifting the standard as a whole. The two fittings are evidently designed with expert knowledge of the practical employment of half-watt lamps in the studio.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Monday, April 11.

Bowes Park and Dis. Phot. Soc. "Improving the Print." W. Bullock.
Cripplegate Photographic Society. "The Choice of a Hand Camera." N. F. Horne.
Leith Amateur Photographic Association. Federation Portfolio.
South London Photographic Society. Platinotype Demonstration.
Willesden Photographic Society. Members' Exhibition.

Tuesday, April 12.

Royal Photographic Society. "Problems of Cinematography." H. M. Lomas, F.R.P.S. "A Shutterless Continuous-feed Cinematograph." R. J. Trump, B.A., B.Sc., A.Inst.P.
Exeter Camera Club. Auction Jumble Sale.
Walthamstow and District Phot. Soc. "Titling the Print." E. W. Brooks.

Wednesday, April 13.

Borough Polytechnic Phot. Soc. Outings Print Competition.
Croydon Camera Club. "The Mounting of Photographic Prints." V. Jobling.
Dennistoun Amateur Photographic Association. "Flashlight Photography." A. Dordan-Pyke.
Ilford Photographic Society. Affiliation Folio.

Hammersmith (Hampshire House) Photographic Society. "A Chat on Ortho-chromatic Photography." A. J. Bull.
Hull Photographic Society. Annual General Meeting.
Kryn and Lahy (Letchworth) Phot., etc., Soc. "Pictorial Work in Great Cities."

Friday, April 15.

R.P.S. Pictorial Group. "The Trimming of the Picture." M. O. Dell.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, April 5, the president, Dr. G. H. Rodman, in the chair.

Mr. C. M. Thomas, M.A., delivered a lecture, "Chemical Methods in Photography: Weights and Measures; Solutions and the Sulphites." He addressed himself to the amateur whose work was on a small scale, who developed a quarter-plate every now and then. Therefore, in what he had to say on weighing chemicals and measuring solutions, he confined himself to small quantities. Mr. Thomas gave an interesting historical survey of the British measures of weight and volume, and pointed out how their very names denoted their origin in Eastern countries. He demonstrated the confusion which is caused by lbs. having different numbers of grams, and their corresponding sub-division into different ounces and drams. Perhaps the more one knows about the British weights and measures, the more easily one can be confused by them. At any rate, the formidable series of measures which Mr. Thomas exhibited in the form of a table provided a useful foil for the simplicity of the French so-called metric measures. He showed the very few simple measures of weight and volume which are necessary in making up formulæ in gms. and c.c.s.

From weighing and measuring, Mr. Thomas passed to developing formulæ, and explained the easy way in which stock solutions could be made up so that the same quantity of each was required in compounding, say, a three solution developer from the stock solutions. He then proceeded to demonstrate by an interesting series of experiments the properties of the commonly used chemicals, sulphite, bisulphite, metabisulphite, and hypo, and, in conclusion, showed a few examples of removal of pyro stain by means of the combined bleach of the silver image and decolouriser of stain, introduced some few years ago by the Ilford laboratories. Alternatively, he showed a negative of quite respectable density formed by the pyro stain alone after the silver image had been bleached out. Some discussion followed, in which Messrs. W. B. Ferguson, O. Bloch, K. Hickman, G. E. Brown, and Dr. Slater Price took part, and a very cordial vote of thanks was accorded to Mr. Thomas for a lecture the interest of which owed not a little to its many passages of dry humour.

CROYDON CAMERA CLUB.

Mr. S. W. Rose in delightfully humorous and interesting style narrated his experiences in the R.A.F., illustrating his discourse with lantern slides.

His first job towards winning the war consisted in washing down corridors. His next was connected with a riding school, presided over by a retired gentleman jockey—retired in both capacities. Considering that Mr. Rose previously had never been bestride even a donkey, the riding school came as a complete and surprising novelty, and from what he said even now an armchair, nicely furnished with cushions, is desirable when recalling this phase of the past. Retiring from the "on and off" business he turned cook, and acquired (so he said) a great reputation for his plum-duff, but lost his job owing to a mistaken idea that sergeants were only entitled to the same rations as their subordinates. It is understood he will give an informal demonstration on plum duff in the summer. The next rôle was that of carpenter, and a little gang had quite a pleasant holiday behind the lines, the sergeant in charge being amiability itself, as he had borrowed from all.

Finally, Mr. Rose drifted into the photographic section of the R.A.F., a description of which formed the main theme of the lecture. The various cameras used and their construction and manipulation were clearly described, also a number of very interesting aero-photographs were shown. The department had to account for all plates delivered to them, and on one occasion a batch developed to a uniform black fog. Inquiry eventually elucidated that the airman, finding the magazine jammed, had, with the best of intentions, removed the plates in broad daylight and re-inserted them. The laws of the Medes and Persians relating to

procedure were, he said, to a large extent abrogated; for instance, all the washing plates and prints received was three quick changes, the first bath soon being capable of being used as an emergency fixer. Nevertheless the prints in his possession had lasted well; they were dried by the well-known expedient of "flashing off."

Perhaps the most striking slides shown were those from panchromatic plates, with and without filters. The way in which a deep filter penetrated haze, which without it entirely obliterated the landscape below, was really wonderful. In reply to a question why 5 × 3⅞ came to be adopted as a standard size instead of 5 × 4, Mr. Rose said some thought this was done to prevent jamming in the magazine. Others held the view that the special size was selected to prevent the plates being utilised in privately-owned cameras. A most hearty vote of thanks was accorded him for a really excellent lecture.

On the preceding Monday the club's Easter outing was held. The weather report prophesied "bright intervals." These were struck at the "Hoskings Arms" at Oxted and the "Bull Inn" at Limpsfield, where some fine old ale was discovered by Mr. Harpur. Despite the wretched weather all enjoyed themselves immensely.

News and Notes.

PHOTOGRAPHERS IN GUILDFORD are making a move towards forming an amateur photographic Society. Those interested are asked to communicate with Mr. E. D. Brown, Trevelyan, Cranley Road, Guildford.

MR. PERCY J. SLATER, Sawtry, Peterborough, for many years a specialist in enlarging and postcard printing, sends us his latest price list for these and other forms of trade work. A postcard addressed to him will bring a copy of the list.

CAMERA REPAIRS.—Messrs. O. Sichel and Samuelson, of 52, Bunhill Row, London, E.C.1, advise us that they have opened a department for the repair of cameras and shutters, and also are in a position to supply plate-holders made to customers' orders.

A NEW WELLINGTON LIST contains descriptive particulars of the firm's many grades of plates and papers, and includes the reduced prices now ruling. Messrs. Wellington and Ward will be glad to send a copy of this booklet to anyone applying to them at Elstree, Herts.

THE OPTICAL SOCIETY.—At the meeting to be held at the Imperial College of Science and Technology, at 7.30 p.m., on Thursday, April 14, Mr. F. Twyman, of Messrs. Adam Hilger, is announced to read a paper on "An Interferometer for the Testing of Camera Lenses."

P.P.A. EXHIBITION.—The following is the list of the jury which have been nominated to judge the pictures for the P.P.A. Congress exhibition:—Pictorial section: Angus Basil, Bertram Park, and Richard N. Speaight. Technical section: Alexander Corbett and H. A. St. George. Owing to the many requests that have been received from country photographers, the judging committee of the P.P.A. Congress have decided to defer the date of entry until Monday, April 11, after which date no pictures can be accepted.

SHEFFIELD AND DISTRICT PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—A meeting was held on Wednesday, March 23, at Miss Ethel M. Eadon's studio, when Mr. H. J. Leslie Cawood gave a short lecture on photographic cost accounts. Mr. Cawood pointed out the advantages of cost accounts when prepared on a proper basis, and the disadvantage of approximate costs. Photographs must be sold at such a price as will attract the public; the selling price was therefore limited, and any additional profits must be earned by reducing costs, *i.e.*, by obtaining additional business, which reduced the percentage of overhead costs. At the close of the lecture several questions were asked, which Mr. Cawood answered. A hearty vote of thanks was accorded Mr. Cawood for his kindness in giving a paper on this interesting and important subject.

PROCESS PLATES—AND A PROCESS PAPER?

To the Editors.

Gentlemen,—With reference to the recent "Assistant's Note" on the use of process plates, I have found one make of process plate to be of very great service for yet another branch of work.

A few days ago I had to copy some water-colour paintings—marine subjects—done entirely in blue pigments; they had to be reproduced in blue carbon to give an exact facsimile of the originals. After failing, for some reason, to get the kind of negative wanted with panchromatic plates and screens, I tried—more as an experiment than anything else—a Barnet process plate (without a screen), and the result was a most agreeable surprise.

I was under the impression that any shade of blue would be rendered as white on a process plate, but the plate named rendered every shade of blue and gave a brilliant negative, with splendid, if slightly increased, contrasts. In other words, the gradation in the negatives was a little steeper than in the originals. In one painting a steamer at sea was pictured, the port-holes of the vessel being in the original only a slightly deeper blue than the hull; one, in fact, found a difficulty in distinguishing the port-holes. In the negative, however, the port-holes showed quite clearly. Details in the waves were also picked out in a really remarkable manner, and I was able to secure better carbon facsimiles than I had hoped. Full development of such plates to "process stage" was not, of course, possible, because by so doing the lightest of the blues—a sky with fleecy clouds—suffered. For copying flat originals (photographs) process plates are undoubtedly the thing, because of the increased contrasts one can so easily obtain.

Why not a process paper, say a paper coated with the process plate emulsion? It may be thought that gaslight paper would serve, but it will not. One cannot get sufficient opacity (when viewed by transmitted light), and one cannot "wangle" the development of gaslight paper so easily as one may dodge development of process plates. A process paper of bromide rather than gaslight quality is wanted, especially by architects and engineers who make plans. A suitable contrasty bromide paper would permit of the enlargement of plans and the use of them as paper negatives; the paper at present available, however, cannot be developed sufficiently opaque.—Yours faithfully,

COPYIST.

A NEW USE FOR COLOUR-SENSITIVE PLATES.

To the Editors.

Gentlemen,—An enterprising contributor to the illustrated magazines has, I believe, discovered a novel use for colour-sensitive plates and light-filters. But should I, by chance, be wrong in my idea, the pictures of his I have before me give me an idea, and I think it well worth attention.

Quite recently the decorated ceiling of a famous London church was cleaned, and the paintings upon it, which had been for generations covered with dirt, and unnoticed by many people, were made clear and bright, the renovators exposing to view a masterpiece of ceiling work by a famous painter of long ago.

The reproduced pictures in question form a pair, one showing the appearance of the ceiling—nearly black and images but faintly visible—before cleaning, and the other a view of the ceiling after cleaning, with the figures very clear and brilliant.

A very careful measurement of these two pictures of the paintings and their surroundings—windows, arches, etc.—and a careful study of the lighting of the same, lead me to believe that both pictures were taken "at one sitting," an ordinary and filterless

plate being used for one exposure and a panchromatic plate with a screen for the companion one.

The great similarity of the ceiling's surroundings struck me as being rather peculiar, and I wondered how the photographer could have managed, after an interval of some weeks occupied by cleaning, to again place his camera within practically a fraction of an inch of the same spot. Then I noticed the titles and particulars below each picture. The very honest editor—or was it the photographer?—did not say that the "dark" picture was taken before the ceiling was cleaned, but that the picture "represented the appearance of the ceiling before cleaning." This rather clever wording confirmed my suspicions, and suggested to me a new use for ex-our-sensitive plates—and "ordinaries" as well, namely, for the picturing of "before and after" effects.—Yours truly,

L. T. W.

HALATION AND DEVELOPMENT.

To the Editors.

Gentlemen,—I was very interested in reading the article in your recent issue relating to development and halation, particularly your statement that in all probability short development is more likely to minimise halation than long development.

Now, my experience is just the opposite, and I would even go so far as to say that prolonged development *with suitable developer* will not only minimise halation, but will do away with it completely.

In support of this statement I enclose for your inspection a P.O.P. print of a photograph which I took on March 26 last on an *unbacked* plate—exposure 6 minutes at *f*/11. Neither the negative nor the print have had any touching-up.

The time occupied in developing this plate was 27 minutes, about 22 minutes in developer and about 5 minutes in plain water, and I think you will admit that there is no trace of halation.

The whole secret is in the constitution of the developer, and the one used in the above case was:—

10 per cent. pyro solution	40 minims.
20 per cent. soda solution	30 minims.
Water up to	1 oz.

This was poured on to the plate, and at the end of 18 minutes the high-lights were just beginning to come through. At the end of 20 minutes the half-tones began to appear, and the plate was then taken out of the developer and placed in a dish of clear water for about 5 minutes; it was then replaced in the developer for one minute, rinsed and fixed.

At the moment this is the only print I have taken from the negative, or I would let you have a better one, but I am sending it, not as a specimen of high-class work, for its faults are many (the two spots at the base of the column are on this print only, and do not appear on the negative), but purely to show that halation can be got rid of by prolonged development provided the developer be rightly constituted, i.e., it should contain a large excess of pyro.—Yours faithfully,

C. H. Mayes.

Arabin Road, Brockley, S.E.

NON-HALATION PLATES.

To the Editors.

Gentlemen,—Referring to the correspondence in the "British Journal" on halation, I beg to inform you that MM. R. Guilleminot, Boespflug et Cie, Paris, have just put on the market a new non-halation plate, which simply consists of a coloured film between the glass and the emulsion. The film underlying the emulsion is formed of manganese peroxide suspended in gelatine. The brown colour of this coating disappears without any difficulty in the acid fixing bath, and has no bad effect on the emulsion like some double-coated plates may have, and for which sometimes special baths must be used.

With these new Radio-Lux Guilleminot, 400 H & D, the high lights and the deepest shadows alike are rendered perfectly.

As advertised, I will be pleased to send samples to any of your readers who are interested in this new production.—Yours faithfully,

Jules de Gottal.

STEREOSCOPIC RELIEF.

To the Editors.

Gentlemen,—With reference to Mr. F. C. Tilney's letter on stereoscopic relief, in Sir David Brewster's interesting book on the Stereoscope (1856), the question of the union of similar pictures is fully discussed, with particular reference to the illusion obtained when wall-paper is viewed with the eyes converging on a near point, and also a more distant point than the plane of the wall. After describing his various experiments, he says, "A friend to whom I had occasion to show the experiments, and who is short-sighted, mentioned to me that he had on two occasions been greatly perplexed by the vision of these suspended images. Having taken too much wine he saw the wall of a papered room suspended near him in the air."

Brewster further suggests this as "an accurate method of discovering defects in the workmanship of paper-hangers, carpet makers, painters, and all artists whose profession it is to combine a series of patterns to form an uniformly ornamented surface."

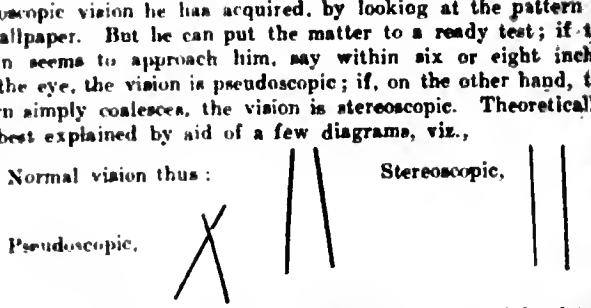
It is an easy matter to converge the eyes on some near point and so get different portions of the pattern overlapping, but then the eyes automatically accommodate for this near point, and the difficulty is to relax the accommodation sufficiently to focus the pattern while keeping the eyes converging on this near point. This may, however, be done with a little practice, when the illusion described by Mr. Tilney will be seen, and it is possible to place the hand apparently behind the transparent wallpaper. It would seem from these experiments that the sense of distance is very largely dependent on convergence, the object always appearing in the plane to which the two eyes converge. Thus with objects in various planes having their images in a stereoscopic slide separated by different amounts, varying amounts of convergence are required to combine the dissimilar images, and the sense of relief is therefore obtained. Although the plane of the whole pattern may be apparently changed, no difference of plane in the various parts will be seen unless there are dissimilarities of the images seen with the two eyes.—Yours faithfully,

W. H. A. Fincham.

Hillfield Avenue, Hornsey, N.8.

To the Editors.

Gentlemen,—I am interested in Mr. Tilney's letter on stereoscopic vision, but if I read his letter right, it is not stereoscopic, but pseudoscopic vision he has acquired, by looking at the pattern of the wallpaper. But he can put the matter to a ready test; if the pattern seems to approach him, say within six or eight inches from the eye, the vision is pseudoscopic; if, on the other hand, the pattern simply coalesces, the vision is stereoscopic. Theoretically, it is best explained by aid of a few diagrams, viz.,



That is, in pseudoscopic vision the right eye sees the left picture and the left eye the right one.

As I am concerned, I can exercise both. Stereoscopic, which I acquired about 30 years ago, when I did a lot of stereoscopic work, and it is very handy when mounting the slides, as it enables one at a glance to see whether the prints are mounted correctly, as it will happen sometimes, in spite of prints being marked L. and R. Thus they will get transposed, and if discovered at once can easily be pulled off and remounted in the right way. The faculty of seeing pseudoscopic I only acquired about ten years ago, and it came about in a peculiar way. I have some floorcloth of a diamond pattern, black and white, and when looking at this, and while I was smoking a pipe, I was looking at the pipe and the pattern simultaneously, and lo! the pattern came up to me within about eight inches of my eyes. I have repeated it hundreds of times, and it is so realistic that I can determine within half an inch where it appears to be, a sort of "fata Morgana," but it does not increase in size, remaining the same size as seen in the distance. Another way of doing this is to put, say, seven

identical photographs on the floor and by looking at them pseudoscopically the three in the centre will rise up to within six or eight inches of the eye.

This subject of seeing stereoscopically and pseudoscopically was fully thresned out in "Photography," and if Mr. Tilney will turn to the issue of April 13, 1909, he will find there, and in some preceding numbers, the subject fully dealt with by Chadwick, Dorman, Adnams and others.—Yours truly, E. FENSKE.

46, Osborne Road, Thornton Heath.
April 4, 1921.

P.S.—Anyone possessing the faculty of seeing pseudoscopically can also see an uncut stereoscopic negative or untransposed point stand out stereoscopically; at least, I can do so quite easily, and there does not seem the slightest strain on my eyes.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. M. F.—(1) We have never heard of it. (2) A fine abrasive of this kind is supplied as Frictol by the Vanguard Manufacturing Co., Maidenhead. (3) Hydroquinone as a developer was introduced by Abney, who thereby no doubt led to the origination of the other organic developers.

P. S. M.—There is no simple chemical rule for the equivalence of soda carbonate and caustic soda or potash in a developer. The relative quantities of these alkalies required to neutralise the same weight of alkali are not measures of the activity of the respective alkalies in this respect.

PELMONT.—Certainly it can be done, but at present there is no advantage in the process, because several times the normal exposure has to be given. Slow plates do not require such a proportionately great increase of exposure but then, of course, their initial lesser speed is just as great a handicap for your purpose.

C. E. T.—Intensification with mercury and ammonia will make the negatives worse than they are at present. The best intensifier for such ghosts of under-exposed negatives is uranium. Another plan is to bleach the negative with bichloride of mercury solution, back it up with black velvet, and copy it as though it were a print.

G. SHELL.—The original papers of Hurter and Driffield are now available in the volume forming part of the memorial to these two investigators. It is edited by W. B. Ferguson, K.C.M.A., who contributes an introduction tracing Hurter and Driffield's work up to the publication of their first paper in 1890. It is published by the Royal Photographic Society, price 25s. net.

N. E.—The idea has been embodied in at least one hand-camera which we remember, viz., one introduced by Messrs. Perken, Son & Rayment, about twenty years ago, but optically it is wrong to move the lens up and down on the arc of a circle instead of at right angles to the lens-axis. Though there are no doubt occasions in which this simultaneous rise and tilt may be useful, the effect on the negative is difficult to predict, and there is liability to the same kind of foreshortening which results from swinging the lens.

S. E. H.—The focal-plane shutter has not necessarily 100 per cent. efficiency, equivalent to a shutter which takes no time at all to open and close, and thus causes the plate to receive the full action of the rays from the lens during the whole period of exposure. But if the blind is close to the plate and not very narrow, the shutter approaches this efficiency. The efficiency becomes less as the distance of the blind from the sensitive surface is increased; also as the width of the slit is decreased; also as the *f* No. of the lens is greater. If all these factors are adverse the efficiency may fall to 40 per cent. or 50 per cent., *i.e.*, much below that of a good diaphragm shutter.

T. F. F.—Impossible to say from the meagre particulars if the method is novel. So many processes of making mosaic colour screen-plates have been patented that it is a reasonable assumption that practically every possible method has been thought of. A year or two in the "Colour Photography" Supplement we collected abridgments of most of the methods published during the previous ten years. The latter was the most prolific period, these methods having been inspired by the success of the Autochrome plate on its introduction in 1907. However, if you think it is worth it, it will only cost you £1 to file a provisional specification. Circular of instructions from the Comptroller of Patents, 25, Southampton Buildings, London, W.C.

B. B.—If, as you say, you have found no ill effects as regards the permanence of the prints, it is not possible for us to condemn the formula—at any rate as you use it. But we are strongly against any acid-fixing bath which does not contain a considerable proportion of sulphite in some form or other. We think the best, and also the simplest form of such bath is made by adding some bisulphite or metal-sulphite to the hypo solution. Either of these salts supplies both the acid (sulphurous acid) to the sulphite which takes up and renders non-injurious any sulphuric produced by oxidation. (2) The best means of obtaining strong acid in a "dry" preparation is acid sulphate of soda, otherwise called sodium hydrogen sulphate. But it is a substance which absorbs moisture very readily, and any mixture containing it requires to be well sealed.

L. G. M.—As we have pointed out scores of times in answers in this column, it is not necessary to do anything at all in order to obtain copyright. Copyright automatically comes into existence by the making of the work—a painting, a book or a photographic negative. Registration as a formality necessary for establishing a legal right is abolished. Therefore if the photographs were taken "on your own," the copyright in them is yours. If, on the other hand, you took them to the order of some other person, the copyright in them belongs to that other person, the fact that you have not been able to obtain payment for them does not transfer the copyright to you. The law provides separate machinery for the recovery of the debt. You could, as you seem to suggest, accept the copyright as payment of the debt, in which case the copyright should be the subject of a written assignment to you.

Contents.

SUMMARY

The Photographic Fair, which opens to-day (Friday) at the Horticultural Hall, Westminster, contains a very representative display of the manufactures of firms in the photographic trade. We publish a series of advance notices indicating particularly the new introductions which will be found at the various stands (P. 211.)

The full programme of the Congress of the Professional Photographers' Association, which is to open on Monday next at the Photographic Fair, will be found on page 220, where also is published a first list of P.P.A. members who have signified their intention of taking part in the proceedings. (P. 220

At its annual general meeting to be held during Congress week the question of incorporation of the P.P.A. under the Companies Acts is down for consideration. (P. 224.)

Mr Elwin Neame's lecture at the Publicity Club last week gave him the opportunity of saying much of interest to the photographer who is a maker of advertisements. A report of his discourse will be found on page 219

In a leading article we endeavour to put forward the view of enlarging as a process which shall be as much a commonplace in photographic manipulation as contact printing now is. On the grounds of efficiency and economy there is much to be said for the universal use of enlarging; and the vertical pattern of enlarger goes a very great way towards simplifying practice. (P. 210.)

M. L. P. Clerc, in the current instalment of his "Paris Notes," contributes a brief sketch of present-day photographic journalism in France, and writes also on the share taken by women assistants in French professional photography, on a new portable studio arc lamp, and on a recent demonstration of the use of a large portrait lens for naturalistic effects. ((P. 217.)

A point requiring attention in the use of the heavy-weight printing papers now much in favour is adequate strength of the springs of printing frame or machine. (P. 210.)

We endorse a recently expressed opinion of Mr. W. B. Ferguson's on the service which plate makers would render to photographic experimenters by stating the composition of recommended working developers in a form, such as grains per ounce or grammes per litre, permitting ready comparison. (P. 209.)

A somewhat greater degree of exposure coupled with a restrained developer will often serve to get presentable results on stale papers or plates. A touch of the iodine-cyanide reducer subsequently will further help matters. (P. 210.)

EX CATHEDRA.

The Congress. In the midst of strikes and rumours of strikes, one thing is certain, and that is, that the Congress of the Professional Photographers' Association will be held. A general railway strike would, of course, reduce its size, but in the worst event a Congress might still be held among those within the London area, although its character would naturally undergo great modification. It is, however, surely inconceivable that the sanity of the British nation has become such a vanishing quantity that the stoppage of the national life for even a few days is a credible conception. Mr. Lang Sims, the secretary of the P.P.A., moving with herculean persistence in these strenuous days, has completed all the final arrangements. He asks us to say that any members of the P.P.A. who have applied for membership of the Congress, but may not have received their badges before their departure for London, should apply to the Commissionaire at the entrance to the Fair, arrangements having been made for their delivery there in the event of uncertainty of postal transmission.

* * *

Developing Formulæ. At the Royal Photographic Society's meeting last week, in the discussion following the lecture by Mr. C. M. Thomas, Mr. W. B. Ferguson, K.C., urged upon manufacturers of plates the desirability of stating in their circulars of instructions the composition of the developing solution as applied to the plate, so that anyone anxious to try the makers' formula could do so without the necessity of making up certain stock solutions, or, alternatively, going to the labour of tedious arithmetical calculations. Mr. Ferguson asked, and it is a request which will be echoed by many plate users, that the composition of the working developer should be stated either in grains per ounce or grammes per litre; preferably in both measures. We recollect that a good many years ago, in the early days of dry-plates, one or two makers did adopt this practice, and the good example which they set no doubt prompted several writers in the Press to take the very great trouble of working out (in grs. per oz.) the composition of all the working developers issued in the various plate makers' instructions. Tables of this kind were published for a few years in the "Year Book of Photography," and about the year 1912 we carried out a similar series of calculations for the developers of both plates and papers and published the results in the "B. J. Almanac." But owing to the complexity of many of the developing formulæ which, no doubt for good reasons, are adopted by plate makers, the calculation of the composition of the working developer is a very tedious business, and in some cases a formula is of such diabolical ingenuity that it is impossible to represent it with certainty in a simple form. For this reason, if for no other, it is certainly worth makers' while to give this recommendation their attention. If makers would all agree to show in a comparable

form the developers which they recommend, it is pretty safe to predict that a number of them would display quite inconsiderable differences, and thus the practice, in addition to facilitating the work of experimenters, would undoubtedly result in a commendable reduction of the number of formulæ.

* * *

A Useful Tool. A most useful and remunerative addition to the kit of the average professional is a quarter-plate reflex camera of a reliable type, fitted with as rapid a lens as possible. With its aid one can easily negotiate many awkward jobs which would be almost impossible with a stand camera, for example, pet animals, certain types of child portraiture, and any moving subjects one may be called upon to take. The ordinary collapsible or Anschütz type is very efficient in its way, but requires more skill in judging distance than most portrait photographers possess; moreover, it does not readily lend itself to a change of lenses. With a reflex a small portrait lens, say of 8 inches focal length, working at *f*/3, can be often used and results obtained which would be procurable in no other way. We counsel the selection of this small size because a half-plate, or even a postcard reflex, with reversing back, is rather an unwieldy instrument and is often relegated to the shelf after a few trials. The quarter-plate size is handy to use and permits of the use of lenses which will give good perspective and extreme rapidity, while the power of accurate focussing gives negatives suitable for enlargement.

* * *

Contact in Printing. Carbon printers have long known that it is unsafe to trust to the ordinary light pattern of printing frame if sharp definition is required, as the flat brass springs which provide the pressure are rarely strong enough, even when new, and rapidly become weaker with use. The tissue which is usually cut from a roll has sufficient spring in itself to prevent uniform contact, and the remedy has to be sought by using the "box" form of frame in which more powerful springs, usually made of steel, are fastened to transverse bars which are pressed down and secured with buttons. Inspection of a number of prints on double weight bromide paper suggests that a similar course might be followed with advantage by those who use this material, for many of the prints showed mysterious fuzzy patches, although the negatives were uniformly sharp. When box frames are used it is almost a necessity to have them fitted with plate-glass fronts, as the very thin glass now used for plates, even of a fairly large size, involves a considerable risk of breakage if adequate pressure be applied. Printing boxes are also often open to criticism on this point, since with these there is often a tendency for the pressure to be uneven.

* * *

Stale Plates and Papers. In these times it goes against the grain to waste plates and papers which have been kept on hand longer than they should have been, and which have consequently developed a tendency to give a slight fog or stain if treated in the ordinary way. When such stale material has to be used a great help towards obtaining clean results will be found in a somewhat liberal but judicious use of bromide of potassium. Protracted development must, however, be avoided, and therefore a rather stronger developer should be used with the necessary bromide added to it. We recently tried an old package of bromide paper which gave deeply-stained prints with normal treatment, but which was quite satisfactory when a more liberal exposure and a restrained developer was used. We have also saved negatives on old plates by using a double-strength developer to which one or two grains of bromide to the ounce had been added. It is worth remembering that the yellow or metallic fog which often appears on stale plates or paper is much more soluble in the iodine and cyanide reducer than the image is, and that it will often disappear before any perceptible reduction of the silver image takes place.

SYSTEMATIC ENLARGING.

THERE is an evergrowing tendency among many of our most skilled photographers to produce a large proportion of their work with the aid of some form of enlarging apparatus, and to issue the prints without any notification of the fact. Only recently one of our best known portraitists told us that all his prints above whole-plate size were enlarged, and that for orders for panels and larger sizes half-plate negatives only were made. Add to this that a highly-skilful trade printer gives it as his opinion that better quality bromide prints can be made through a lens than can be obtained by contact printing, even when the print has to be the same size as the negative, and we have a strong case for the systematic use of the enlarger. Assuming that the question of quality is thus disposed of, we will deal with that of convenience; with a well-designed apparatus there should be little, if any, more labour in using it than there is with the ordinary printing box, if like the latter the enlarger is kept ready for immediate use.

Daylight, on account of its variability and the fact that it is only available for a limited time, especially in the winter, cannot be regarded as a satisfactory source of illumination, so that some constant artificial light must be employed, and in most cases the gas-filled or half-watt electric lamp will be found satisfactory, for, while the light is inferior in intensity to the arc, it is powerful enough for all ordinary work and, being uniform in its light, prevents the waste caused by the fluctuations of the latter. Moreover, its form lends itself admirably to use in the vertical form of enlarger, which we are convinced is the most suitable for everyday work.

In towns where no electric current is available the inverted incandescent gas burner may be adopted and will prove an efficient substitute, although, of course, the exposures will have to be longer.

The design of such an enlarger having been repeatedly published and the fact that more than one model is on the market renders it unnecessary to go into details of construction, our object being to point out to what a slight degree enlarging differs from contact printing. When enlarging is carried out in the way we advocate, the majority of prints will be made in a fixed ratio of size, let us say two diameters, and for these what is practically a fixed focus enlarger may be used. The procedure is then nearly identical with contact printing, that is to say, the negative is laid upon a glass shelf above the lens and the bromide paper laid or held upon a shelf below, exposure being made by means of the usual treadle arrangement. Sometimes, however, it will be found that a much more acceptable result can be obtained by using only a portion of the negative, and, for this reason, a focussing adjustment should be fitted, so that from a full-length negative a three-quarter or even a bust picture may be made to the standard size.

The degree of enlargement should be moderate; that is to say, that from two to three times linear will be the limit, which should not be passed if the prints are to be

issued with only ordinary spotting. A ground glass diffuser between the light and the negative is absolutely necessary, otherwise the grain of the image and the marks of the retouching medium will be unpleasantly obvious. The negative should be brilliant, but not too vigorous, a degree of vigour which would barely give a good contact print being just right for enlarging. The retouching should be fine in texture, and if the focus be slightly softened it will be even less apparent than upon a contact print from the same negative. This may be effected by using a flat field lens and putting the image *very* slightly out of focus, or by using a lens which has a soft focus adjustment, and by focussing as sharply as possible after determining the desired degree of softening.

The system we have outlined should appeal strongly to the professional worker, not only upon the score of economy, which is considerable, but upon the control which can be exercised over the printing; shading, vignetting and any other dodging can be done much more readily than in contact printing. Again, there is the advantage from an optical point of view of being able to work at a greater distance from the sitter, thus securing not only better perspective but also greater depth of definition when using large apertures. We have found the advantage in child portraiture of making small negatives, say, three by two inches, and enlarging to cabinet, instead of working full size in the ordinary way. When taking the small negative a slight movement backward or forward, which would have been fatal on a larger plate, had practically no effect.

For "at home" portraiture, and even some classes of commercial work, small negatives have many advantages. Interiors which would call for an aperture of *f*/64 on a 15 x 12 plate are better rendered with *f*/32, or an even larger aperture, upon a 5 x 4 or half-plate. The only objection that can be raised is the trouble of enlarging, and this we have shown can be reduced to a minimum, the balance being greatly in favour of the small size, when we consider not only the cost of large plates, but of large apparatus and the ever-recurring cost of transport.

The appeal will not be so strong to that minority who print in platinum or carbon, but even they will find a well-arranged enlarger a much better tool for making enlarged negatives than the usual daylight camera. All that is needed is to substitute a plate or flat film for the bromide paper to obtain an enlarged transparency, or to place a small transparency on the negative shelf, if that method be preferred.

Although we advocate the vertical enlarger for ease in working, equally good results can be obtained with lanterns of the ordinary form, the only difference being that the negative has to be fixed in a holder, and the paper has to be pinned upon a board or fixed under glass in a printing frame easel. When working to one standard size it is not difficult to overcome the latter difficulty, as witness the excellent balanced easel which was used by the Royal Air Force at the front.

In conclusion, we suggest that as a rule the best results in portrait work are to be obtained upon a rather slow, soft-working paper. Some of the so-called "soft gaslight" brands are quick enough for enlarging and give better results than the ordinary bromide, but this is a point for the individual worker to decide for himself. If a man does not know when he has got a good picture there is no hope for him. If he does know a good thing let him experiment till he finds it.

THE PHOTOGRAPHIC FAIR.

Again the stand capacity of the Horticultural Hall, Westminster, has been taxed to the utmost by the requirements of the firms wishing to exhibit at the Photographic Fair, which opens to the public to-day. We learn from the organising secretary, Mr. Arthur C. Brookes, that a number of firms have been unable to exhibit, or have had to content themselves with a smaller space than they desired, on account of the impossibility of providing further room. Since the Fair remains open only until to-morrow week, April 23, it would have been impossible for us to have reviewed the exhibits earlier than our issue of the 22nd had we deferred matters until the actual stands could be visited. By courtesy of the exhibitors, however, we are able to give what we believe is a fairly complete and accurate account of the displays by the various firms.

Although the past year of "peace" has provided all kinds of obstacles to the development of the photographic industry, and particularly as regards that part of it concerned in the manufacture of apparatus, it will be found that the stands at the Fair contain quite a considerable number of new introductions, many of which are introduced at the Fair for the first time to the photographic public. Among these, as our notes will show, are the following:—

Distinctive development papers.
Collodion self-toning paper.
Dye-impression printing process.
Daylight film developing tank.
All-metal film cameras.
Folding reflex cameras
Telephoto lenses.
Cameras for aerial photography.
Print drying machines.
Lens hoods and view meters.
A soft focus lens
A new developing preparation
Hand cameras for stereoscopic photography.
A walking-stick tripod, the large head of which completely folds into the handle.

In connection with the Fair the Congresses of the Professional Photographers' Association and of the Photographic Dealers' Association, which will be held during next week, were assured up to a few days ago of a record attendance. The preliminary list of members of the P.P.A. who have already signified their intention of taking part in the Congress of this body is larger than it was at the corresponding period last year. At the time of writing the uncertainty which still prevails in reference to the disastrous dispute between the miners and mineowners and the strike of railway men threatened in connection with it is unfortunately almost certain to act as a deterrent upon many of those at a great distance from London, who, but for this, would certainly have been present at the Congress. It is to be hoped that the spirits of the new age in which we are will at least soon manage to find some method of remedying their grievances other than holding up the whole community to ransom, while, at the same instant, they label themselves communists.

The exhibition of professional and technical photography, organised by the Professional Photographers' Association, will also be open to all visitors to the Fair. As was the case last year, its hanging is in the competent hands of Messrs. Marcus Adams and Angus Basil, but since the exhibition will not be open to view until the time that these pages are published, we cannot say anything about it until our issue of next week.

Stand No. 1—Kodak, Ltd.

Eastman Portrait Film will receive special emphasis in the Kodak exhibit in the shape of a fine collection of prints made from negatives on it and representing the work of leading professional photographers. These exhibits are not only portraits, but also commercial work made with the "commercial" and "commercial ortho" grades of the Eastman flat film. Appliances for the handling of the film, tanks, sheaths and carriers, will also be on view. Visitors will further have the opportunity of seeing in working the Eastman projection printer, which will be installed in a dark-room for this purpose. This self-focussing enlarger is perhaps the most perfect machine ever introduced for the use of photographers. A special feature of it is the employment of transparent specially surfaced screens for the purpose of introducing various definite degrees of diffused definition into the enlargements.

On the dealer side the exhibit of the Kodak Co. will include a display of Kodak cameras, accessories and Velox pictures, arranged in two windows, the dressing of which, by the company's expert, will be changed each day. The aim here is to show what effective window displays can be produced at very little cost. Professional photographers, as well as dealers, can hardly fail to pick up valuable hints from these displays, and, moreover, will have the opportunity of personally getting the advice from the company's expert, by whom also a lecture on the subject is to be delivered at the Dealers' Congress on Friday, April 22.

Stand No. 2—Wratten Division of Kodak, Ltd.

The Eastman aero cameras will be included in the exhibit of the Wratten Division, and the automatic model of these new introductions will be shown in operation. As regards the Wratten specialties themselves, these will include examples of the latest filters and specimens of the work which can be done in the reproduction of coloured objects by means of the Wratten panchromatic plate and the process panchromatic—an object-lesson in a large proportion of the work which falls to the lot of the commercial photographer.

Stand No. 3—C. S. Baynton.

It is announced that the exhibit of Mr. Baynton will consist, as it has done on recent occasions, of a full range of his "Turbine" print washers, including an illuminated working model.

Stand No. 4—Johnson, Matthey and Co., Ltd.

The salts of the precious metals, the manufacture of which constitutes a branch of Messrs. Johnson, Matthey's business, make an attractive and enviable exhibit. Silver nitrate, and even gold chloride and potassium chloroplatinite, are much more seldom handled by the photographer than in former years, but it is good to see the crystalline purity in which these substances are prepared for the manufacturer of sensitive materials. Messrs. Johnson, Matthey's name has long been the hall mark in this respect, and their exhibit usefully serves to remind photographers of their unique relation to the manufacture of plates and papers.

Stand No. 5—Sanger-Shepherd and Co., Ltd.

The student of orthochromatic photography, or of sensitometric experiments on negatives or prints, will always find a good deal to interest him among the instruments made by Mr. Sanger-Shepherd's firm. Graduated light-filters and filters for three-colour photography enter into the former field, whilst Messrs. Sanger-Shepherd are the only people who provide the photographer with instruments (some of them quite simple and inexpensive) for the measurement of the speed of plates and properties of negatives. These include the even and step wedges of various kinds by the use of which investigations of exposure and development, and particularly of the ubiquitous gamma, are greatly simplified.

Stand No. 6—R. and J. Beck, Ltd.

Messrs. Beck's latest introduction is a new telephoto lens, providing within itself focal lengths of 6 ins. and 15 ins., yet of back focus that it can be used at a camera extension such as that available in the ordinary half-plate reflex. The provision of two definite focal lengths appears to be a new feature in telephoto lenses, and one which probably satisfies the needs of the many photographers who have little use for very long foci. Another new exhibit is a new camera for photomicrography, and, of course, Messrs. Beck will show their Isostigmar, Neostigmar and Bystigmar lenses, the latter an $f/6$ objective which is separable into two single lenses of $f/11$ aperture.

Stand No. 7—The Platinotype Company.

Demonstrations of the extreme simplicity of the manipulation in Platinotype printing are always an attraction, and they will be of frequent occurrence at the stand of the Platinotype Co. The name of the firm, however, no longer fully represents its manufactures, for the abnormal price of platinum metal has brought into existence the two other printing processes, Satista and Palladiotype, the manipulation, and also the results, of which are closely akin to those of Platinotype, whilst the prices of the materials bring the processes within the means of those who, from motives of economy, have been compelled regretfully to choose a less costly medium than platinum for the printing of their negatives. The supremely beautiful qualities of the three printing processes will be illustrated by specimen prints.

Stand No. 8—The Autotype Company.

A twofold address to photographers, both professional and amateur, is now made by the Autotype Co. If you can print by daylight, there is the carbon process; but for manipulation entirely by artificial light, there is Carbro, in which the halfway house is a print on bromide or gaslight paper. In either case you get a carbon print with its distinctive quality of texture and with its range of colour and its facility of being produced on any surface. Demonstrations of both processes are to be given, and the Autotype Co. will also show a few specimens of their excellent service to the professional photographer in the making of carbon and bromide enlargements, finished in various distinctive and most artistic styles in monochrome, water colours or oils. Miniatures, on ivory or ivorine, with or without a photographic basis, and finished in water colours, are also a specialty of theirs to which prominence will be deservedly given.

Stand No. 9—Marion and Co.

A leading feature of this stand is examples of the remarkable results, as regards quality and shortness of exposure, obtained on the recently introduced Iso Record plate. Half-tone reproductions, such as have been used in Press advertisements, while effectively drawing attention to this new power in negative making, cannot adequately represent the standard of quality which goes with it. A soft-focus lens is a further new introduction at this stand, where also professional photographers in particular should note two rapid print-drying machines. The machine print-drier as a time-saving and labour-saving appliance has come slowly into use in this country in comparison with its wide adoption in the United States, and the professional portrait maker will be interested in examining these two commercial driers, which are priced respectively at £73 and £35.

Stand No. 10—Adams and Co.

Messrs. Adams are showing for the first time an improved and perfected design of the folding "Minex" reflex camera, an instrument of beautiful design and workmanship, in which every facility of the box pattern of reflex is obtained, including extension ample for the use of the single component of the lens with which the camera is fitted. The speed with which the camera is brought into the working position for exposure, and alternatively is folded again after use, must be witnessed by those who are disposed to disparage the folding type of reflex on the ground of the time required in making ready for an exposure. The camera, as we have said, embodies all the movements, including great rise of front,

swinging front and others which have long been familiar in the earlier box models of the renowned "Minex" camera, with the single exception of the automatic masking device geared to the rotating back. Another new introduction at Messrs. Adams' stall is a walking stick tripod, the 5½-inch triangular head of which folds within the tripod itself, and when the latter is erected provides a solid support even for a half-plate reflex. The stand, as we have had an opportunity of observing, is exceedingly rigid. Other exhibits by Messrs. Adams are de luxe models, both plate and roll-film, of the "Vesta" folding camera, and also a less expensive model fitted with an f/6.8 lens. Another specialty is a stop-watch exposure meter, in which a first-class stop-watch has a simple exposure meter arranged in the back. The watch may be had with the complete ordinary movement or as a timer, recording seconds up to 1 minute and minutes up to half an hour. Messrs. Adams will also show their watch pattern of exposure meter of extraordinary slimness and very beautifully made in nickel.

Stand No. 11—Taylor, Taylor and Hobson, Ltd.

Messrs. Taylor, Taylor and Hobson will exhibit a series of specimens illustrating the processes of manufacture of both the glass and metal work of lenses, and will have a machine in operation showing lens grinding. Moreover, it is a machine of their own design and manufacture, and represents an advance in the machine surfacing of lenses with an enormous degree of accuracy. The exhibit will, of course, include examples of the new Cooke "Aviar" lenses, originally designed for aerial war work. There will also be shown a new Cooke telephoto lens, providing new facilities in telephotography, and a cinematograph taking lens of recent introduction. Autochromes and enlargements made with Cooke lenses will draw attention to these optical manufactures.

Stand No. 12—Leto Photo Materials Co., Ltd.

The renowned self-toning "Seltona" paper is always the staple exhibit of the Leto Co., of attraction not only to amateur workers, but to many professionals, who find in this printing medium a solution of many printing difficulties. We are advised this year of a novelty relating to the paper in the shape of "Seltona Transfer," the nature of which we have still to definitely learn. A new edition of the Seltona "Perfect Prints" will be issued at the Fair, and the exhibit will also display the many attractive styles for both amateur and professional prints which are provided by the double-weight "Boardoid" papers and by the plate-markers and border negatives which are Leto specialties.

Stand No. 13—O. Sichel and Samuelson.

As suppliers of professional photographic requisites of all descriptions, Messrs. Sichel and Samuelson will devote their exhibit largely to appliances for the business of photographic portraiture. These include a Simplex drying machine, a new pattern of printing machine, cutting and bevelling machines and backgrounds and a background stand. Mounts and frames are requisites in which the firm has long specialised, and the present exhibit will include a collection of the latest styles in oval frames.

Stand No. 14—Ross, Ltd.

These many lenses and cameras will form the exhibit of Messrs. Ross, Ltd., and will provide both the professional and amateur photographer with a great deal to interest them. The qualities of Ross lenses in portraiture will be demonstrated by a striking life-size portrait of Mr. Lloyd George, taken by Messrs. Wakefield, of Chiswick, with a "Homocentric." Messrs. Ross will also advertise their advertising by bringing together a display of the very striking showcards and other advertising publications by which they are assisting dealers in the distribution of their goods. The Ross cinematograph projector, to which we referred a week or so ago, will also be on exhibition, and if not quite within the sphere of interest of most visitors to the Fair, will serve usefully to demonstrate the very great perfection of the mechanical work done in Messrs. Ross's workshops.

Stand No. 15—Kosmos Photographics, Ltd.

The Kosmos Co. has a nice sense of showing its wares, and the stand in the classical Greek style, which was a notable feature of last year's Fair, will this year contain a collection of examples of portraiture by the well-known Paris firm of Reutlinger and by many leading English workers. These, with other prints and enlargements, will serve to demonstrate the remarkably fine and varied results obtained on the Kosmos "Vitegas" paper, particularly in reference to professional work. The many amateurs who took part in the recent Kosmos contest and secured prizes therein will welcome the opportunity of seeing enlarged reproductions of many of the winning pictures and of obtaining prospectuses and entry forms for the forthcoming Kosmos competition, in which £1,000 is to be distributed in prizes. Attention will also be directed to the firm's "Novex" gaslight paper, very popular with amateurs, as well as with photographers and dealers who undertake the developing and printing of amateurs' films. The Bromoil process is also one of the fields of Kosmos activity, on account of the special suitability of "Vitegas" paper for the preparation of the print, and the company's technical literature on this subject will be obtainable at the stand.

Stands Nos. 16 and 17—Houghtons, Ltd.

The dealers in amateur photographic requisites obtain the chief consideration at these stands, for Messrs. Houghtons are bringing together their appliances for professional photography in a special exhibit which will be accommodated in a room on the first floor of the hall adjoining the meeting place of the P.P.A. Congress. Here will be shown the firm's latest appliances for the studio, dark-rooms and printing rooms, including apparatus for strip printing, washing and drying.

At the above stands in the body of the hall the exhibit will represent the firm's resources as manufacturers of plate and roll-film cameras in a large range of types, from the waistcoat pocket "Ensignette," which appears as an aluminium model, to the folding focal-plane camera and the series of Sanderson cameras, both hand and stand. Messrs. Houghtons also have their reflex cameras, including a folding model, and their range of other accessories extends over the whole field of amateur photography and includes the scores of appliances and accessories, the possession of which is the ambition of the amateur worker.

Stand No. 18—Thornton-Pickard Manufacturing Co., Ltd.

A new model of T.P. reflex camera, namely, one for horizontal pictures, will be shown at the Fair, and the exhibit will also include the company's All-Weather press camera. Naturally enough, the old-time specialties of roller-blind shutters and stand cameras will take a leading place alongside the later developments in the shape of folding cameras of various types for film and plates, as well as the series of Thornton-Pickard enlargers.

Stand No. 19—Newman and Guardia, Ltd.

Without question, the latest thing in apparatus at the Fair will be the new folding N. & G. reflex camera, the first of which that has been completed we have had an opportunity of seeing. It is for 3¼ × 2½ pictures, and by most speedy movements is opened into the working position in which, by a lazy-tongs pattern of side support, the lens front and baseboard are held with extraordinary rigidity. We are not yet familiar with the mechanical movement by which Messrs. Newman & Guardia have achieved this simplicity, but the quickness with which the camera is got ready for use from the closed position and folded again is almost uncanny. A new focal-plane shutter gives a wide range of instantaneous speeds, with quick and positive adjustment for "time" and "bulb." There is a rotating back and a swing front, as well as very ample rise of front. In short, all the movements of a box-form reflex with the single exception of double extension, and in these days of large-aperture fixed-focus telephoto lenses the occasion for double extension in a hand camera has largely disappeared.

The beautiful "Sibyl" folding cameras will compete in interest with the new reflex, and will include the additional facility of taking, from the Baby "Sibyl" upwards, a telephoto lens, such as the Ross "Telecentric" or Dallmeyer "Dallon," interchangeably with the normal *f*/4.5 objective.

Stand No. 20—W. Butcher and Sons, Ltd.

The Carbine film tank for the daylight development of roll-film, a notice of which appears in another column, will be shown and demonstrated by Messrs. Butcher, and should not be overlooked by amateur visitors to the Fair, since it is a notable addition to the equipment for easy photography. And, of course, Messrs. Butcher will have a large exhibit representing their series of plate and film cameras, including the popular "Cameo's" and "Klimax's (for plates) and "Carbine's" and "Maxim's" for roll film. There is also the "Pressman" reflex camera, one of the lightest and most compact of reflector instruments. Enlarging lanterns are also apparatus of which Messrs. Butcher are leading manufacturers, and the intending purchaser of an enlarger will be well advised to take the opportunity of examining the merits of the "Abbeydale" and "Record" enlarging lanterns and the "Clincher" daylight enlarger.

To the professional photographer the part of the Butcher exhibit of chief interest is that of mounts and mounting papers, and, particularly, the altogether excellent series of ready-made passe-partout frames which during the last year or two Messrs. Butcher have brought into existence in a whole series of most artistic styles. Cinematograph apparatus, cameras and equipment for developing and printing of film, as well as cinematograph projectors, will also be shown.

Stand No. 21—White Band Manufacturing Co., Ltd.

By way of emphasising their early entrance into the field of developer manufacture during the war, the White Band Co. are showing an advertisement, published a few weeks after the outbreak of hostilities, in which reference is made to the fact. Naturally, they are giving prominence to their products Monomet, metol and amidol, and will exhibit specimens showing the different stages of manufacture from the raw material. But a large branch of the company's business is in the supply of ready-made developing and other preparations, as compressed tablets ("Pakoids"), and in packet and carton form. They have also a special preparation of their own in the shape of a photographic mountant.

Stand No. 22—Acme Art Association.

This old established firm of colourists and portrait painters for professional photographers will show the artistic merits of its productions in the shape of oil paintings and water colour and pastel drawings. Its technique includes work in these media both with and without a photographic basis. Miniatures are also a specialty of the Acme Art, in which branch it is able to offer its customers the service of Royal Academy exhibitors.

Stand No. 23—F. Brodrick, Ltd.

Dark-room apparatus for the professional or trade worker will form an exhibit in which printing machines for films or plates, tanks for their development and fixing, and washers for negatives and prints will be shown. Among the latter is the cascade pattern of washer, the most efficient type for quantity work, solidly constructed in teak. The professional photographer or dealer undertaking the development of amateur's film negatives cannot afford to neglect Messrs. Brodrick's exhibit.

Stand No. 24—City Sale and Exchange.

As British agents for the renowned Paris firm of Jules Richard, the City Sale and Exchange are devoting their entire exhibit to the cameras and other apparatus, such as the "Verascope," "Taxiphote," and others of world-wide repute. The "Verascope" stereoscopic hand camera will be shown in nine different models, including one fitted with a shutter made to give, at its highest speed, an exposure of 1-400th of a second. These cameras employ plates of the standard "Verascope" size of 45×107 mm., and the realistic stereoscopic effects obtainable from the positive transparencies made from them will be demonstrated by means of the several different patterns of stereoscope, both hand and magazine, which have been designed for their use. There are also larger models of "Verascope" for plates 6×13 cm. or 7×13 cm., and we must not omit to mention the exceedingly ingenious "Homeos" camera, which we described in these columns a month or two ago, by which 26 pairs of stereoscopic pictures are taken on a length of cinematograph film and are printed on positive film for viewing in the stereoscope. The camera itself, no less than the printer and stereoscope, which are supplied for use with it, is a triumph of fine workmanship and most ingenious design.

Stand No. 25—Criterion, Ltd.

The distinctive qualities of the various Criterion printing papers will be demonstrated by an exhibit which makes a specific appeal to widely separated classes of professional or commercial photographers. For example, the utility of the "hard" and "extra hard" grades of bromide paper for the making of press photographs will be illustrated by specimens of news photography made on these papers. The artistic merits of rough cream, cream and white canvas, and platino-matt Criterion bromide papers for professional portraits will be demonstrated by examples by leading photographers, and the special qualities of the Criterion portrait gaslight paper will be brought to notice by means of a series of prints from negatives by Miss Compton Collier. The striking effects obtained on red-toned bromide prints will be shown in the shape of theatrical photography by the Stage Photo Co. And the amateur worker will be able to see the results in Bromoil and Carbro which are yielded by Criterion bromide, as well as the lantern transparencies made on Criterion special lantern plates.

Stand No. 26—James A. Sinclair and Co., Ltd.

We are glad to hear that Messrs. Sinclair are resumning the manufacture of their N.S. "Perfect" shutter after a long war interval. It was a pioneer step of theirs to guarantee the accuracy of the speeds by a National Physical Laboratory certificate, and one which, in view of the prevailing mendacity of speeds engraved on shutters, is to be encouraged. Messrs. Sinclair are also showing the new model of their lens-hood which we reviewed a week ago, and also a new form of combined direct-vision finder and view-meter, so arranged that it can be kept on the camera or removed, as desired. Those altogether excellent "Una" cameras will also enter into the exhibit, and the intending Bromoil worker, who seems to be the care of exhibitors this year more largely than ever before, is here encouraged to embark upon the process by the offer of a complete set of apparatus and materials at the cost of a few shillings.

Cinematography represents the highest achievement of the manufacturing side of Messrs. Sinclair's business in the shape of the Newman-Sinclair camera and accessories. We need not refer further to the camera, since a brief outline of its remarkable mechanical features appears on another page.

Stand No. 27—Reginald E. Carter, Ltd.

Another of the many exhibits at the Fair which will be almost exclusively professional. Photograph frames in wood, metal and leather, and also cases and rims for miniatures, are specialties of this firm, which are offered in many exclusive and beautiful styles Another important item among professional requisites is dry-mounting tissue, the "Mayfair" brand of which will be specially brought to the notice of visiters. And Messrs. Carter, as agents for Messrs. Bartons, of Birmingham, will be able to make an exceedingly fine display of mounts and mounting papers, folders and albums, and the very artistic and strong metal binding for framing in the passe-partout style. The unerring good taste of Messrs. Bartons in the art of mount design is, we think, generally acknowledged among photographers. Those who have not had the opportunity of studying these mounts ought certainly not to neglect the opportunity which the Fair provides.

Stand No. 28—J. H. Dallmeyer, Ltd.

Since the last Fair Messrs. Dallmeyer have brought out their new series of "Dallon" fixed-focus telephoto anastigmats of such large apertures as f/5.6, f/6.5 and f/6.8 in focal lengths from 5½ to 17 ins. These lenses, the fine optical performance of which will be shown in photographs, require on the average a camera extension of about half the focal length. Thus, they have a great interest for the amateur worker desirous of obtaining the more pleasing drawing which results from a narrow angle of view and at the same time of reducing the weight and cost of his camera. Messrs. Dallmeyer will show these lenses fitted to N. & G. "Sibyl" cameras. Another new series of anastigmats is the "Perfac," Series V., whilst no Dallmeyer lens exhibit would be complete without the Patent Portrait lenses, the Stigmatics and the Dallmeyer-Bergheim soft-focus lens. A reflex camera for nature photography will also be shown fitted with a Grandac telephoto, giving 25 ins. focal length at 6 ins. camera extension at an aperture of f/10.

Stand No. 29—John J. Griffin and Sons, Ltd.

As specialists in the supply of professional requisites of all descriptions, Messrs. Griffin will exhibit a variety of recent introductions. Among these will be the "Goodrick" dry-mounting fixing irons, gas and electric, which we recently noticed; also the Charles series of flash lamps; "Howellite" gaslight outfit for studio portraiture; "Barkay" studio reflectors for use with artificial light, and Griffin card bevellers and cutters. These will be only a few of the many items of equipment of a portrait establishment which will find a place on Messrs. Griffin's stand.

As manufacturers of photographic papers and chemical preparations, Messrs. Griffin will also draw attention to their gaslight, self-toning, P.O.P. and bromide papers, and to their chemical specialties, such as "Mequin" developer, acid fixers and chemical preparations for the Bromoil process.

Stand No. 30—Elliott and Sons, Ltd.

As a rule in the past no firm brings together a more artistically pleasing and photographically excellent display of prints and enlargements than Messrs. Elliott, who have a sure instinct in making, mounting and framing prints for exhibition. Among those to be shown this year are a number illustrating the new Barnet bromide paper, "Bartona," yielding prints of warm black colour by direct development. But tints and surface textures are specialties of Messrs. Elliott, in the incorporation of which with their sensitive emulsions they have outdistanced many other firms. We conclude from the list of the exhibits which they have sent to us that their display this year at the Fair will be no less effective than that on previous occasions in demonstrating the very refined results which are obtainable on their many grades of bromide and gaslight paper.

Stand No. 31.—Johnson and Sons.

Messrs. Johnson will introduce a new developer in tablet form at the Fair, namely, "Vedol," for the use of which time and temperature development tables have been worked out for the assistance of those developing by rule. Vedol is a universal developer, suitable for bromide and gaslight papers, as well as for plates and film, and lends itself also to the making of lantern slides in a range of warm colours. As in former years, Messrs. Johnson will prepare their exhibit from specimens of the chemicals of their manufacture required in every branch of photography and supplied by them in the forms most convenient to every class of worker—in tablets, packets and solutions for the amateur, and bottled in bulk for the professional. Their "Scales Brand" of tablet preparations will receive prominent notice, and so also will the developing substances metol, amidol, glycin, pyro, hydroquinone and Azol, manufactured by them and guaranteed by the distinctive trade mark of the name of their firm.

Stands Nos. 32 and 33—Gevaert, Ltd.

Among the many Gevaert plates and papers will be shown for the first time results on a new rapid gaslight paper for direct warm black prints by simple metol-hydroquinone development. The Gevaert manufactures cover the whole field of negative making and printing. Plates for the former range from the extreme speed "Sensimm" to less rapid emulsions, and include an orthochromatic, a non-filter ortho and an anti-halation plate. Among printing papers, there is P.O.P., self-toning (collodion), bromide and gaslight to choose from, and the special de luxe "Partox" gaslight paper for direct brown tones by special development. Pictorialism of their specimens employed to represent adequately the technical merits of materials is usually a strong point with Messrs. Gevaert, and no doubt this year's exhibit will be no exception to that rule.

Stand No. 34—Bean and Halliday.

As makers of mounts and mounting materials from first to last, Messrs. Bean & Halliday will be able to bring together a most comprehensive exhibit of mounts, folders, albums and wallets, and will devote a good deal of care to shewing their manufactures with suitable photographs mounted thereon. Their specialties include also all descriptions of mounts, slip-in, etc., for amateur requirements, and a special line is calendars for photographers who do commercial work. They will also show specimens illustrating their department for the supply of photographers' stationery.

Stand No. 35—Adhesive Dry Mounting Co., Ltd.

Dry-mounting, from its facility of demonstration, always makes an attractive exhibit, and the Adhesive Dry Mounting Co., as the originators and pioneers of the process, can be depended upon to show the latest developments in it, and the most recent appliances in the way of mounts and albums, trimming boards and hot presses. Their manufactures cover both the professional and the amateur range of these goods, so that a photographer of whatever class should be able to satisfy his dry-mounting needs at this stand.

Stand No. 36—J. Lizars.

Messrs. Lizars will show their new model Challenge all-metal folding film-plate camera, one notable feature of which is that the plate in its holder registers in focus with the roll film, obviating the adjustment of the focussing scale and thus facilitating the alternate use of these two different forms of sensitive material. The camera is made both of single and of double extension, the former having a novel type of lever focussing. The exhibit will also include other patterns of the "Challenge" hand and hand-stand cameras, among which are models with the excellent feature of being built to take views the landscape way of the plate, and possessing a full range of movements as regards rise and fall and swing of front, drop of baseboard and bellows extension.

Stand No. 37—Robinson and Co.

Messrs. Robinson's exhibit is one of those which ought to be seen, and must be seen, for their work as water-colourists in the making of enlarged portraits for photographers is very fine, and no amount of written description can convey an adequate idea of it. They are the originators of quite a series of distinctive styles in portraits to which they have applied names of their selection, so that a customer who has ordered work in a given style can be reasonably certain that further orders of portraits similarly named will be executed in accordance with his anticipations. In these styles a distinctive background plays a large part. For example, the "Regal Panel" is done with a grey ground, and with drapery sketched in with chalk. In the "Court" series a very striking effect is obtained by means of a perfectly black ground and black mount. The "Pastel" is a buff panel masked on larger cream paper, whilst in the "Gainsborough," for head and shoulders portraits, a background in the style of those of the Old Masters is sketched in. There is a freshness about Messrs. Robinson's work due to the skill with which they use their

chosen medium, namely, water colours, and we should draw particular attention to the very artistic frames which they supply, of wood moulding with a metal surface, which may be had in imitation of pewter, silver, bronze or gilt, and is guaranteed to keep its colour for 10 years. Messrs. Robinson are also themselves miniature painters on ivory, ivorine and paper, and make a special point of guaranteeing the likeness, failure to do which is often a disappointing incident in commissioning portraits of this kind.

Stand No. 38—Thomas Illingworth and Co., Ltd.

Messrs. Illingworth are making the Fair the occasion for bringing prominently to the notice of professional photographers their new developing paper "Zona," yielding prints of warm black tone and exceedingly fine gradation by straightforward development. A large selection of prints in this new medium will be shown. We need not refer at greater length to the paper in these notes, since we have something to say about it on another page of this issue. The portrait photographer must certainly not omit to see these prints in Messrs. Illingworth's exhibit, which is happily situated *immediately opposite the refreshment bar*. By arrangement at the stand, demonstrations of the development of "Zona" and other papers may be witnessed in a dark-room, which will be fitted up in the basement of the hall.

Messrs. Illingworth's large resources in the manufacture of development papers will also be displayed in reference to their grades of portrait bromide, including "Bromide de Luxe," bromide paper for commercial and press photography, and the special paper for X-ray work. For amateurs and for dealers who work for them there are the papers, such as "Slogas" gaslight, "Enitone" self-toning and P.O.P. The exhibit will include a selection of prints on "Slogas" from amateurs' films. Finally, dominating the refreshment bar itself is an enlargement, measuring 12 ft. × by 54 ins., printed upon a single piece of Illingworth bromide paper.

Stand No. 39—Wellington and Ward.

A new Wellington paper—collodion self-toning—will make its bow to the photographic public at the Fair. It is to be obtainable in three grades of surface, matt, glossy and cream chamois, in each case of both thin and thick substance. The paper will be demonstrated at frequent intervals, as also will be the use of Wellington S.C.P. (gaslight paper) and the toning of bromides. This year Messrs. Wellington, who always are very artistic exhibitors, will arrange their stand as a panelled interior covered with wall paper of refined design, and will show their pictures masked and plate-sunk on large sheets of paper, a form of print which, in the style of its production and framing, will provide useful object-lessons for the professional arranger of a reception room, as well as for the amateur who applies his photography to home decoration.

Messrs. Wellington & Ward are one of the few firms who exhibit negatives, always of interest to the amateur worker when they are of the fine quality of these on Wellington plates, and can be compared with prints or enlargements on various papers. This year S.C.P., the distinctive Wellington gaslight paper, will be given special prominence in respect to its usefulness to dealers and photographers undertaking the development and printing of amateurs' films. It is significant that many of the exhibiting firms are laying special emphasis upon this growing business. But the Wellington exhibit will be a comprehensive one of the results on plates and papers and with chemical preparations, the names of which are household words among photographers.

Stand No 40—Witt and Westley.

Mounts and mounting materials for the professional photographer are to form this exhibit by a firm which for many years has shown its keen sense of what is desirable in photographic mounts. Inasmuch as these goods are among the most difficult to describe in words or illustrations, makers of portraits have good reason for appreciating the opportunity of examining at their leisure the many styles of folders, covers, sketch boards, etc. Metal, inlaid and passe-partout frames are also among the firm's specialties, and Messrs. Witt & Westley are agents for the Akron dry-mounting machines and for the dry-plates of the Mawson Co.

Stand No. 41—The Paget Prize Plate Co.

For the supremely fine effects obtainable on self-toning paper the visitor will examine with interest the display of the Paget Co., for many years in the forefront in the manufacture of this description of sensitive material. There are also the several varieties of Paget gaslight paper, including Gravura, with its range of colours by modification of exposure and development. Paget bromide papers receive emphasis of their merits in the shape of enlargements from negatives, many of which are made on Paget plates, and the amateur interested in colour photography will not fail to see for himself the simplicity of the Paget process and the excellence of the results by it.

Stand No. 42—Colin Campbell.

Mr. Campbell will personally demonstrate his process of cold dry-mounting by means of a special adhesive preparation which is applied with a brush and does not require the use of a press. Every photographer will be interested in seeing the actual manipulation in this distinctive process of mounting.

Stand No. 43—Burroughs Wellcome and Co.

Although their products have reached a pitch of perfection and a range of variety which admit of little difference being made in exhibits of them from year to year, Messrs. Burroughs, Wellcome always contrive to show something out of the ordinary for the interest of their customers. This year it consists of 250 quarter-plate and 5×4 prints, all developed with the contents of a single 2s. carton of "Rytol." They illustrate the keeping qualities of "Tabloid" chemicals by enlargements from negatives developed with them on Sir Ernest Shackleton's expedition in the "Endeavour." Tabloid toning preparations likewise are illustrated, and there is, of course, the ever useful compact and comprehensive Exposure Diary.

Stand No. 44—Ilford, Ltd.

While the merits of their many manufactures will be shown in the shape of prints, enlargements and transparencies, Messrs. Ilford, Ltd., will arrange some very interesting technical displays by way of demonstration of the quality of both new introductions and goods which have long possessed an enviable reputation. For example, the visitor will have the opportunity of testing for himself the superiority of a newly introduced light-filter, the "Aviol," for the absorption of ultra-violet light, over that prepared with the German dye Filter Yellow K. Ultra-violet light emitted by a fluorescent screen of barium platino-cyanide will be available for viewing alternately by the two filters, and the advantage of the new dye thus seen at a glance.

Another exhibit consists of a series of eight prints from as many negatives made on Ilford "Special Rapid" plates with exposures ranging from 1 to 8. The plates were exposed in rapid succession, and were all developed together in the same pyro-soda developer for the same length of time. Inasmuch as the subject itself possessed a considerable range of light-intensities, it will be understood that the remarkable uniformity of the prints is an eloquent testimony to the great latitude of the plate. As a comparison, results obtained on plates of another make under the same conditions will be shown.

The advantages of panchromatic plates in the photography of polished woods and in process work will also be shown by means of exhibits, and Messrs. Ilford are including a series of colour prints from negatives made on their "Rapid Process Panchromatic" along with the original subject—a case of butterflies. Negatives made on "Zenith" plates of H. & D. 525, and lantern slides showing the magnificent range of tones on "Alpha" lantern plates will also form part of the exhibit.

Stand No. 45—E. B. Fry, Ltd

Inasmuch as Messrs. E. B. Fry supply their manufactures only through dealers, their name is perhaps less familiar to actual users than that of many other firms in the photographic trade. But they are very large makers, and in some cases the sole makers, of requisites which are in daily employment by both professional and amateur workers. Materials for passe-partout framing are a specialty of theirs, and include binding strips in a range of 32 colours and surfaces, together with hangers of several perfected types evolved by themselves and protected by patent. They issue a 16-page manual on passe-partout framing, in which every detail of the process is described and illustrated, and a number of attractive varieties of passe-partout framing indicated. The business of supplying these requisites has grown from Messrs. Fry's world-wide trade in lantern-slide binders and masks, which have achieved their success largely through the unique qualities of the adhesive applied to the strips, a virtue which is still more appreciated in the case of passe-partout binders. As makers of masks, Messrs. Fry have very thoroughly supplied the needs both of amateur workers and of those doing printing and development for amateurs by issuing a whole series of masks both in transparent light-tight celluloid and in paper. One series of particular interest to the trade printer is a set of transparent masks for making white-margin prints, all of half-plate size (outside dimensions), but provided with printing apertures down to the No. 1 "Ensignette" size. Such a series obviously provides great facility in the making of masked prints by means of a printing box. In short, for a great many of such requisites as these, which enter into the making of prints and transparencies, Messrs. Fry's exhibit is one specially to be studied.

Stand No. 46—Dye Impression Photos, Ltd.

The method of making prints from a dye negative by contact simply, without exposure to light, will be shown at this stand, where the visitor will be able to see the facile way in which prints are made, and, moreover, will have the opportunity of seeing exactly the kind of negative, on paper, which it is necessary to get for the best results in the prints. Examples of the results of the process will be shown, and the complete manipulation in the shape of the dyeing of the negative and the taking of prints from it will be shown in actual working.

Stand No. 47—Iliffe and Sons, Ltd.

Messrs. Iliffe occupy a stand which provides bold advertisement for the "Amateur Photographer," and for the many books on photographic subjects published from the offices of our contemporary.

Stand No. 48—Raines and Co.

Owing to the large demand for space at the Fair Messrs. Raines have not been able to make a very large display representing the many branches of their service for professional photographers, but their wall exhibit will demonstrate in an admirable manner the very high quality of their work as artists, colourists and enlargers. One feature of the exhibit will be a collection of miniatures on ivory, painted in their own studios, and representing a department of their business in which they are able to give close and personal attention to the commissions received from portrait photographers. Other work, which we have had an opportunity of seeing at their Ealing studios before its departure for the Horticultural Hall, is a small selection of the styles in enlarged portraits in which they are regularly working. These include pencil sketches, crayon drawings, and several portraits in water colours on a grey base, the artistic technique of all of which is of a very high order. As compared with the more delicate gradations of a photographic print or enlargement, such portraits of moderate size possess a strength, the quality of which is, perhaps, not sufficiently appreciated by photographers. It is shown by the striking way in which the work retains its character when viewed from a distance, say from the other side of a room, whereas a photographic print in like circumstances loses a good deal of its quality. Nevertheless, Messrs. Raines very rightly give prominence to the excellent results of straight photographic enlargements if made so as to secure the very best results from the negatives. In illustration of this they show a number of enlargements made by them from photographers' negatives without any retouching whatever beyond the spotting out of mechanical defects. The enlargements very forcibly emphasise their contention that in this work the best is the cheapest, since a photographer who makes or obtains an inferior enlargement can easily double its cost through the necessity of afterwards making good its defects by working up. The fine photographic quality of these enlargements is certainly an object lesson.

Stand No. 49—Peerless Photo Paper Co.

The qualities of a new make of portrait developing paper will be shown at this stand in the shape of a large collection of specimen prints. The Peerless Co. manufactures a wide range of development papers, and will also show the results on its gaslight paper for amateurs and on bromide paper of dead matt surface. Prints on P.O.P. and on other papers will also be shown.

PARIS NOTES.

Photographic Journalism in France.

As in my previous letter ("B.J.," March 11) I gave an account of the French Photographic Society, which is the headquarters of photographic activity in France, I may perhaps say a few words on the French photographic Press as it exists at the present time.

Technical journalism in France is in a less favourable position than in England. On the one hand, French is spoken by a much smaller number of people than is English, so that the field which is open to the publisher of a technical journal is smaller; circulation is therefore smaller, and the cost per copy correspondingly greater. On the other hand, manufacturers and dealing firms in France make use of advertisement to a smaller extent than is the case with English or American firms, which again operates adversely upon technical publications. Also the present cost of production is at a very much higher level, whilst circumstances do not allow of the sale price being correspondingly increased

The several periodicals de luxe, which formerly were devoted to photography, such as the "Bulletin of the Photo-Club of Paris" (and the "Revue de Photographie" which followed it), "La Photographie Française," and "Photo-Gazette," were compelled successively to suspend publication during the years 1905 to 1912. The attempts which have been made to issue annual publications, somewhat resembling the "British Journal Photographic Almanac," have not met with success. "La Revue des Sciences Photographiques," a first series of which appeared from 1904 to 1906, and which was revived in 1911, had its career stopped by the war and has ceased to exist, a fate which it shared with a number of minor journals appealing to amateur photographers.

The number of photographic periodicals which now have a life of their own, that is to say, do not exist by lifting matter which has been published elsewhere, is very small at the present time. The first of them which should be mentioned is the "Bulletin of the French Photographic Society," the

oldest French photographic publication. It appears monthly, but, unfortunately, for several years past has been about three months late in publication, so that the communications to the Society are made public with considerable delay. Next comes a group of three journals, managed with great energy by a newcomer in photographic journalism, M. P. Montel. These are "Le Photographe," established in 1910, published twice monthly, and appealing to professional photographers; "La Revue Française de Photographie," established in 1920, also published twice in the month, and catering for amateur photographers. Since the beginning of the present year each issue of the "Revue Française" contains a supplement of not less than four pages, entitled "Science, Technique et Industrie Photographiques," in which are published, without loss of time, abstracts of articles, etc., appearing in all the scientific or technical journals relating to photography and its applications, as well as brief summaries of inventions patented in France, England, United States and Germany. [M. Clerc omits to say that the excellent review of the current periodical literature of photography to which he is here referring is done by himself.—Eds. "B.J."] The third journal of the group is "L'Informateur de la Photographie," a monthly publication for dealers in photographic goods, distributed gratuitously to all retailers. The first issue appeared in March of the present year. In addition to the foregoing trinity of publications, which between them represent a circulation much greater than that of all the other journals put together, must be mentioned "Photo-Revue," the oldest of the amateur journals in France, which formerly was issued weekly, and the only one which maintained regular publication (but monthly) during the war. This journal now appears twice in the month. There are also a monthly review, "Le Procédé," of photo-mechanical processes, and some other publications of minor importance.

It is to be regretted that art criticism, which is such a feature of some of the English and American photographic journals, finds no place in the French publications. No doubt, as a result, the artistic level of the work of most amateurs is exceedingly low, as was shown in the competition organised last year by the Chambre Syndicale des Fabricants de la Photographie, which nevertheless was an important competition, since numerous prizes were offered, including one of 10,000 francs.

Shadow Detail and Short Exposures.

I read with interest, in the recent paper by Mr. G. I. Higson on "The Action of Light on the Photographic Plate" ("Photographic Journal," March, 1921), the following conclusion (p. 149):—"From this result it might be expected that the rendering of shadow detail by short exposures with lenses of great aperture and a rapid shutter would be better than with slower lenses and a slower shutter for the same value of exposure, *but the author is not aware if this effect has been noticed.*" The italics are mine.

This observation of Mr. Higson provides the long-sought explanation of the very remarkable results obtained by means of the camera which about 20 years ago was constructed, to the number of a few instruments, by the late M. Guido Sigriste. M. Sigriste, who was a painter of repute of historical scenes, required for some of his battle pictures accurate records of the positions taken by horses in movement. Being dissatisfied with the cameras obtainable, he himself made one of the focal-plane type permitting of exposures as short as 1-5000th of a second, and having a shutter efficiency of 100 per cent. The metal-edged slit travelled at a distance of less than 1-250th of an inch from the sensitive plate. This camera, fitted with a "Planar" lens, which at that time had the largest relative aperture obtainable, gave results of which M. E. Wallon, after having described the mechanism of the shutter ("Bull. Soc. Fr. Phot.," February 1, 1900, pp. 73-84), wrote as follows:—"These prints exhibit excellent gradation; the values are rendered in a manner which certainly is more correct (in many cases the difference is very great) than that which obtains in ordinary instantaneous photographs, or even from negatives which have received time exposures. I state this as an experimental fact, without endeavouring to explain it. . . . . ."

M. Sigriste established, in conjunction with his painter's studio, a workshop in which a small number of these remarkable cameras were made, but their price, which was relatively high for that time, proved an obstacle to the commercial success of his enterprise. Occasionally one of the cameras is met with second-hand, and it is noteworthy that, despite the apparent fragility of the mechanism, these instruments are invariably in as perfect condition as when they were made. It should be added that M. Sigriste, who was of Swiss nationality, but for many years had made his home in Paris, whilst over age for mobilisation by the Swiss authorities, entered the French army on the declaration of war and lost his life in the service of France.

Women's Work in Photography.

A question asked by a reader of the "British Journal" respecting the opportunities for the photographic employment of women in France has led me to make inquiries among the heads of the trade associations as to the opportunities for women in French studio establishments. Whilst, among amateurs, one can call to mind numerous women whose works have obtained distinction at the various exhibitions, it is scarcely possible to name half a dozen professional studios for portrait photography which are, or were, managed in Paris by women, and of this number barely half of them are run by Frenchwomen. Yet it would be a great mistake to conclude from this that there is no place for women in French professional portrait photography. In many studios the woman takes an active share in the management of the business with her husband, and it should be added that during the war the women entirely replaced men who were serving with the armies, not only on the commercial side, but also in the studios and other branches. In many cases they did so with the help of men disqualified from age or other causes for military service. Woman labour is, however, fairly largely employed in French studios, but not for such different kinds of work as in England. Women are employed chiefly for mounting and finishing prints; occasionally for retouching (the best women retouchers are foreigners), and, to a much smaller extent, in bromide printing.

Portrait Lenses.

One of the most skilful Parisian photographers, M. G. Cromer, has recently brought to the notice of the French Photographic Society the views which he holds as regards the properties of a lens yielding portraits in correspondence with the effect which is seen by the eye. As a result of our binocular vision, we see a little more to the left with the left eye and a little more to the right with the right eye than would be the case if we saw things from a single view-point in accordance with geometrical perspective. This seeing-round effect is further enhanced by the unconscious movements of a person to one side or the other from a midway position of equilibrium. For the purpose of obtaining an equivalent effect by photographic means, M. Cromer considers that the portrait lens should have a diameter of about 5 inches, or as near that size as possible. In order to avoid the excessive sharpness which a Petzval lens tends to give in a single plane of the sitter, he places at some distance at the back of the lens a sheet of "papier glace" (transparent gelatine, as used for tracing) of about 1-100th of an inch in thickness, which yields a slight degree of diffusion and renders the image more homogeneous, the outlines being softened to a greater extent as the gelatine film is placed nearer to the lens. This arrangement was very successfully demonstrated at a meeting of the Society by M. Benjamin, a well-known Parisian photographer, on the occasion of the establishment of a new studio portrait section of the Society.

Desensitising Plates.

As in England a preparation, Desensitol, has been made available by Messrs. Ilford, Ltd., for the desensitising process

of Dr. Lüppo-Cramer for the development of plates (even panchromatics) in full light, a similar product is being supplied in France by the firm of Calmels, and has given every satisfaction to those who have tried it. One of the most skilful Autochrome workers, M. Ch. Adrien, has used the desensitiser in this process so as to allow of development being done in ample yellow light, and has obtained perfect results. The dye is destroyed by the acid permanganate reversing bath, but the desensitising effect appears to persist, and therefore it is necessary to carry out the second development in a sufficiently strong actinic light.

Relief on the Screen!

The inventor of the concave screen mentioned in the previous instalment of these notes has had to abandon, so it is stated, the claim that the screen gives the effect of relief to pictures which are projected on it and to confine himself to the claim that a better visibility of the picture is obtained from all points of a projection theatre. In reply to the letter of Mr. R. W. Blakeley, which appeared in the "B.J." of March 25, p. 178, I must be allowed to say that the word "stereoscopic" was not used in the paragraph in which I mentioned this screen.

A New Studio Arc Lamp.

A new arc lamp, named the "Pistolet Studio," in reference to the resemblance of its shape to that of a pistol, and intended for use in the hand or on a light stand, has been introduced by the firm of Sautter-Harlé, specialists in the construction of searchlights and projection lamps. It is for use with continuous current as an auxiliary source of light in cinematograph and photographic studios, particularly for obtaining a concentrated lighting on parts of the subject. The lamp weighs less than 7 ozs. and has long carbons, the light from the crater being controlled by a spherical metal reflector which is polished or matt according to circumstances. For lighting, the negative carbon, which projects behind the reflector, is pushed by the finger until it touches the positive carbon, and is then let go. A spring, which is the only mechanism of the lamp, brings it to the required separation for normal working during three or four minutes, after which all that is necessary is to adjust the carbons by contact. The lamp is of such small size that after the handle has been detached it can be fitted on the burner of an ordinary oil lamp and used for the ordinary reading lamp effects of home portraiture. Owing to the special carbons which are employed, this lamp yields a light of from 5,000 to 6,000 candles for a consumption of 8 ampères at about 65 volts.

More Taxes.

Two branches of the photographic industry are particularly hardly hit by increases in taxation or creation of fresh taxes necessitated by the failure of the Germans to carry out the obligations which they accepted under the Treaty of Versailles. The cinema theatres have been subjected to progressive taxation, the total of which at the present time in the case of the large theatres may amount to 40 per cent. of the gross receipts. The view postcard trade, on the other hand, has received a severe blow by the raising of the postal rate on picture postcards from 5 to 20 centimes. The disastrous effects of these heavy advances in taxation have not been long in making themselves evident, and an active campaign is being undertaken by the respective trades with the object of obtaining some measure of relief. The cinematograph industry has cleverly applied its experience in stagecraft to enlisting public sympathy. On the occasion of the Mi-carême festivals it arranged for a number of vehicles to traverse the leading Parisian thoroughfares. On them were arranged stage settings representing in a most effective way the heavy imposts of which this important industry is the victim.

L. P. Clerc.

PHOTOGRAPHIC ADVERTISING.

At a meeting of the members of the Publicity Club of London, held at the Hôtel Cecil on Monday, April 4, Mr. Elwin Neame (Elwin Neame, Ltd.) gave an interesting lecture on "Photographic Advertising." For the purpose of demonstration he brought with him one of his famous models for showing the methods of securing unusual effects when photographing millinery, costumes, etc.

In the course of his lecture he said that in America advertisers used photography to a very much greater extent than in this country. Photography was not only on a level with line or wash drawings, but it could be of even better advertising value. The reason photographic advertising was not used to such a large extent in this country as in the States was because, generally speaking, our half-tones were of the cheaper variety, *i.e.*, of the coarser screen, and the quality of the paper generally used was not equal to that used in the States. There were certain colours which were very difficult to photograph, such as light blue on a white background; and yellow and purple also required careful handling, because yellow photographed dark and purple came out very light. Black and white was the ideal combination for photographing, and that was the reason why the American cinema producers almost invariably dressed the leading lady in black-and-white check. Fur coats were excellent to photograph, though black sealskin was rather difficult in goods of that class. Mr. Neame pointed out that most manufactured articles, in the shape of shirts, costumes, etc., were usually made in a variety of colours, and it was up to the advertising agent to see that the photographer was supplied with the most suitable colour scheme for his catalogue illustrations. In the manufacture of men's shirts, if they were made with a light blue stripe on white, it was fairly certain they were also manufacturing the same model with a black or dark grey stripe on a white ground, the dark stripe naturally solving the photographer's difficulty.

With regard to millinery, he said in this country at the present moment nearly every manufacturer of hats was using photographs to illustrate his productions. No doubt there were still a few not yet alive to the possibilities of photography, but he felt sure they would all fall into line in the near future. If a reader of a paper saw a very nice drawing of a hat in an advertisement, there was no guarantee that the hat actually existed other than in the imagination of the artist who had drawn it. When, however, one saw a real photograph of a hat on a model, surely that had a bigger pull and was more likely to create a sale.

Referring to the boot and shoe trade, he mentioned that a few years ago a boot manufacturer would purchase a photograph or painting of a pretty girl's head, and place underneath it the wording, "So-and-So's Boots are the Best," and retire to rest for a few months, feeling that he had coped with all the advertising possibilities of his goods. To-day the boot manufacturer is much more particular. He desires the picture of someone immaculately shod and stockinged, with the general garb in keeping with the particular style of boot or shoe. He further requires that the model shall be doing something interesting, to make a direct appeal to the users of goods of the type illustrated. His letterpress is persuasive, and points out why his boots and shoes are better than those of other manufacturers. "I predict in the future," said the lecturer, "that he will resort to X-ray photography, and, if possible, X-ray and colour photography combined, to show exactly how the placing of the heels and soles takes away the strain on spine, and, naturally, brain." [Mr. Neame tells us that on the day following the lecture he received a 'phone communication from the editor of the "Footwear Organiser," in which he stated that in the current number they were showing X-ray photographs of shoes and boots in reference to the American idea of limiting the height of the heel of women's shoes, and he informed the lecturer that in the States they were using X-rays to ensure perfect fitting.—Eds. "B.J."]

The lecturer pointed out, as one of the big difficulties of catalogue illustration, that often the garments sent did not fit the model. This, however, was easily overcome by having several models of known measurements to fit any reasonable stock size, and, where possible, by a model being properly fitted by the manufacturer of the garment before any attempt is made to take the photograph. This is now being done in many cases, and the

results are equal, if not better, and certainly of more selling value, than any wash or line drawing produced. Referring again to the boot and shoe industry, the lecturer mentioned that he was told, on good authority, that nowadays people will not buy from line or wash drawings, as in so many cases the sample differs to such a great extent from the illustration submitted.

Mr. Neame finished his lecture by demonstrating his methods of tackling various propositions to obtain the necessary effects to produce telling illustrations. The lecture was followed by an hour's questioning, in which the lecturer scored all the time.

BADGE NUMBERS OF CONGRESSMEN.

Provisional List.

The following are the badge numbers of members of the Professional Photographers' Association who will be attending the Congress. The list is, of course, not complete, since it represents only applications received up to almost a week before the opening of the Congress. Even so, it may usefully serve in enabling Congressmen from different parts of the country to become known to one another :—

Members of Congress.

1. Frank Brown, Leicester (President).
2. A. Swan-Watson, Edinburgh.
3. Richard N. Speaight, London.
4. Alfred Ellis, London.
5. H. A. St. George, London.
6. Marcus Adams, London.
7. Angus Basil, London.
8. Alexander Corbett, London.
9. C. F. Dickinson, Dulwich.
10. S. H. Fry, Ripley.
11. W. E. Gray, London.
12. Reginald Haines, London.
13. George Hana, London.
14. F. G. Wakefield, Chiswick.
15. W. B. Chaplin, Windsor.
16. H. A. L. Chapman, Swansea.
17. Gordon Chase, Bromley.
18. T. Chidley, Chester.
19. W. Illingworth, Northampton.
20. Herbert Lambert, Bath.
21. F. Read, Southport.
22. H. C. Spink, Brighton.
23. T. C. Turner, Hull.
24. W. H. Wedlake, Forest Gate.
25. Halksworth Wheeler, Folkestone.
26. R. Lang Sims (Secretary).
27. B. Matthews, Bradford.
28. A. H. Anderson, Bradford.
29. E. E. Balley, Kingsbridge.
30. J. P. Clarke, Cambridge.
31. F. H. Sanderson, Cambridge.
32. Douglas Wayland, Streatham.
33. J. W. Carrick, Upton Park.
34. J. S. Simnett, Burton-on-Trent.
35. J. Speight, Sutton Coldfield.
36. W. Davey, Harrogate.
37. F. W. Clark, Forest Gate.
38. W. T. Cook, Caterham.
39. W. H. Cox, Luton.
40. C. Speight, Kettering.
41. A. W. Dron, Brondesbury.
42. D. Osborne, Treharris.
43. A. Barratt, London.
44. Miss A. Cooper, Birmingham.
45. R. Dowty, Douglas.
46. R. W. Brown, Weston-super-Mare.
47. W. H. Brown, Weston-superMare.
48. W. T. Carter, Rochdale.
49. E. Carter, Rochdale.
50. Miss V Blacklock, South Hampstead.
51. Mrs. Carrick, Upton Park.
52. M. Sander, Stoke Newington.
53. J. G. Vesey, Eltham.
54. G. Shotter, London.
55. Mrs. Shotter, London.
56. G. N. Futcher, Southsea.
57. A. B. Fry, Highbury.
58. F. Flemming, Nottingham.
59. W. Coles, Watford.
60. A. C. Watts, Catford.
61. Miss Ivy Weston, Folkestone.
62. A. Hester, Upper Clapton.
63. J. Short, Nottingham.
64. A. R. Pickett, Bexley Heath.
65. F. Notcutt, Plymouth.
66. G. W. Jones, Kingston-on-Thames.
67. E. A. Wakefield, Ealing.
68. Mrs. Frank Brown, Leicester.
69. Mrs. Angus Basil, London.
70. Miss E. M. Eadon, Sheffield.
71. T. A. Scotton, Derby.
72. Mrs Gordon Chase, Bromley.
73. T. Lee Syms, Tyldesley.
74. T. A. Cornall, Harrogate.
75. S. H. Greenway, Northampton.
76. E. Noble, Grimsby.
77. H. J. Kempsell, Wallington.
78. W. S Hiscox, Middlesbrough.
79. Miss Daisy Day, Bishops Stortford.
80. Miss Clara Osborne, Birmingham.
81. J. Charlton, Canterbury.
82. A. Handford, Croydon.
83. Miss Aieleen Sherlock, Caterham Valley.
84. Miss Judith Farrants, Chorlton-cum-Hardy.
85. E. E. Carter, Romford.
86. Miss L. A. Grinyer, Birmingham.
87. F. Gegg, Evesham.
88. J. Cecil Gould, Weybridge
89. G. W. Cooper, London.
90. Miss A. Jameson, London.
91. A. Bennett, London.
92. Oscar Owers, Southsea.
93. H. Wayland, Blackheath.
94. A. E. Elsy, Hampstead.
95. T. Richards, Newark.
96. H. Abrahamson, Hackney.
97. Guy Hughes, Pwllheli.
98. Miss B. Belton, St. John's Wood.
99. H. O. Thompson, Newcastle.
100. D. B. Seaman, Liscard.
101 S. A. Chandler, Exeter.
102. L. Wood, Brighton.
103. S. Hedgeland, Maidstone.
104. F. G. Paget, Ilford.
105. R. H. Gresewell, Southport.
106. H. Bentley, Barrow-in-Furness.
107. G. Morton, Carlisle.
108. Major W. Wade, Middlesbrough.
109. J. Edwards, Oldham.
110. C. E. Willis, Bolton.
111. G. W. Herbert, Lancaster.
112. S. Darby, West Bromwich.
113. Mrs. Darby, West Bromwich.
114. B. Williams, Bristol.
115. A. W. H. Weston, Northwood.
116 G. A. Wilkinson, Bradford.
117. S. Bibbs, Muswell Hill.
118. F. Hodge, Bowes Park.
119. W. J. W. Stocks, Uppingham.
120. G. Couper, Watford.
121. H. P. Hider, Ealing.
122. A. G. Tooth, Porth, Rhondda.
123. Mrs. T. C. Turner, Hull.
124. Eric C. Turner, Hull.
125. Neville Turner, Hull.
126. G. J. Heaton, Lavender Hill.
127. C. Borup, Streatham.
128. W. Emery, Willesden Green.
129. Miss Chapman, Swansea.
130. W. H. Hawkings, Plymouth.
131. H. G. Dorrett, Tooting.
132. P. A. Martin, Tooting.
133. E. Sweetland, High Wycombe.
134. E. Hadley, Nottingham.
135. H. P. Robinson, Red Hill.
136. A. Hands, Wanstead.
137. J. H. Coath, Liskeard.
138. F. Scrimshaw, Leeds.
139. F. S. Scrimshaw, Leeds.
140. E. Albone, St. Neots.
141. Miss Elsie Ames, Blackburn.
142. Arthur Winter, Preston.
143. J. P. Bamber, Blackpool.
144. Mrs. Bamber, Blackpool.
145. Miss Fanny Weston, Northwood.
146. Miss Lena Connell, London.
147. E. H. Skillman, London.
148. H. Shrubb, Bow.
149. H. Harrison, Bow.
150. Mrs. Harrison, Bow.
151. F. W. Payne, Drogheda, Ireland.
152. E. Payne, Drogheda, Ireland.
153. A. P. Cook, Luton.
154. Norman Grut, Guernsey
155. P. Blackbeard, New Cross.
156. F. Robinson, Camberley.
157. F. Thurston, Luton.
158. F. W. Thurston, Luton.
159. Miss Thurston, Luton.
160. A. Jepson, Leeds.
161. T. R. Hammond, Conway.
162. Rudolf Eriksson, Swedish P.P.A.
163. Mrs. Hester, Clapton.
164. J. Cowley, London.
165. W. W. Dowty, Worcester.
166. B. W. Fisk-Moore, Canterbury.
167. R. H. Pickard, Leeds.
168 W. E. Bull, Witham.
169. Mrs. Dickinson, Dulwich.
170. Madame Estelle, Mill Hill.
171. W. Jenkins, London.
172. H. Snook, Reigate.
173. Mrs. W. E. Gray, London.
174. W. E. Blacker, Sutton.
175. G. Hall, Wakefield.
176. Walter Scott, Bradford.
177. E. Virgo, Sydenham.
178. S. H. Wood, Darlington.
179. J. Brunton, Sevenoaks.
180. J. Hughes, London.
181. G. A. Hale, Farnham.
182. E. W. Trangmar, Brighton.
183. Fred. Spalding, Chelmsford.
184. W. White, Goole.
185. M. W. Medcalf, Mexborough.
186. Argent Archer, London.
187. P. P. Crowe, Reading.
188. Herbert Vandyk, London.
189. F. A. Smith, London.
190. Archer Clarke, London.
191. J. Keogh, Dublin.
192. T. Moxon, Folkestone C.C.
193. R. H. Rice, Waltham Cross

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Full Congress Programme.

Monday, April 18.—The members will assemble at 7 p.m., and will be received by the President, Officers, and members of Council. General Conversazione. The President will deliver an address.

Tuesday, April 19.—Morning left vacant to enable members of Congress to inspect exhibits in the Photographic Fair.

Afternoon, 2.15, demonstration by Mr. A. C. Braham (Autotype Co.) of the Carbro Process. Meeting for the discussion of business matters relating to the profession. Ten-minute papers :—

(1) "Salesmanship in the Photographic Business," A. C. Watts, Catford.

(2) "Reasons Why You Should Insure through the Medium of the P.P.A.," by a representative of the Eagle & British Dominions Insurance Co.

(3) "Canvassing Frauds, and How to Deal with Them," by S. H. Greenway, Northampton.

(4) "Dark Room Illumination," by a representative of Kodak, Ltd. Evening, 7 p.m., Mr. S. H. Fry in the chair. "Architectural and Technical Photography," by H. W. Bennett.

Wednesday, April 20.—Morning, 11 o'clock, by kind permission of the Rt. Hon. the Lord Mayor of London (Alderman James Roll), the Congress members, under the guidance of Alderman Sir Louis Newton, will be conducted through the historic and interesting Guildhall and Courts. The Congress members will assemble in the Guildhall Yard, Cheapside, at 10.45 a.m.

Afternoon, 3.30.—Sir William Jury extends to 80 Congress members an invitation to a demonstration of "Prizma" motion colour photography at Jury's Imperial Pictures, Ltd., 19, Tower Street, Upper St. Martin's Lane, W.C. Tickets may be obtained upon application to Mr. Lang Sims.

Evening, 7.—Mr. Richard N. Speaight in the chair. "Photographic Portraiture from a Woman's Point of View," Madame Yevonde.

THURSDAY, APRIL 21.—Visit to the works of Messrs. Kodak, Ltd., at Harrow. A special train will leave Euston at ten minutes past one. No railway tickets will be required. The number of the platform from which the train will start will be notified on the station "departure" board. Upon arrival the official group will be taken and refreshments will then be served. The programme of the tour of inspection has been timed to enable the members to reach Euston at 6.30 p.m.

Evening, 7.—Mr. Swan Watson (Edinburgh) in the chair. "A Talk about Continental Studios and Methods," N. E. Luboshez.

FRIDAY, APRIL 22.—Morning, 11.—A second invitation to 80 Congress members to Jury's Imperial Pictures, Ltd. Tickets may be obtained upon application to Mr. Lang Sims.

Afternoon, 3.—Mr. Marcus Adams in the chair. "Psychology in the Studio," C. P. Crowther.

Evening, 7.—Annual dinner at Gatti's Restaurant, 436, Strand. Evening dress optional. Installation of Mr. Swan Watson, of Edinburgh, as President of the Association, 1921-22.

This programme is subject to alteration.

New Apparatus.

The "Carbine" Daylight Film Developing Tank. Made by W. Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4.

A new pattern of roll film developing tank is an introduction of theirs which Messrs. Butcher will show at the Photographic Fair, and where, we are sure, it will attract the favourable notice of the amateur worker. The tank is made for six exposure spools, and is obtainable in three sizes, the smallest for films taking a picture about 1¾ x 2½, the second size for the number 2 E "Ensignette," and the largest for Nos. 1 and 2 "Brownie" cameras and 2¼ A and B "Ensigns." An outstanding feature of the tank is the remarkably small number of its parts. These are simply the tank itself, a lid, and a long framework, or plunger, which passes through the lid, the appearance of the tank with the plunger nearly in the lowest position being shown in Fig. 1. For the insertion of the band of film into the tank in full daylight, the wrapping paper is unrolled as far as the caution mark and the loose end of the film securely fixed with a gummed label. The spool is then placed in a holder and the holder in turn placed in the enlarged mouth of the tank. Having drawn the plunger up through the lid to its full height the lid is put on, the loose end of film projecting outside and being nipped between the lid and the tank. The latter, it should be said, is previously charged with the developer. On now thrusting down the plunger, whilst the loose end of paper is firmly held, the film is pushed downwards by the lower part of the plunger frame and is thereby exposed as a long loop to the action of the developer. The operation of thus loading the film into the tank is very quickly done and without any opportunity, so long as reasonable care is taken, of going wrong. As a means of agitating the developing solution at intervals during the progress of development the tank is provided with a tube entering the tank at the bottom and having a rubber bulb on its upper end. The bulb has only to be squeezed once or twice in order to cause a current of air bubbles to pass up through the developer, and thus to prevent it from becoming stagnant. After development the film may be washed whilst still in the tank by running a stream of water through from top to bottom, or may be taken out of the tank, quickly rinsed under the tap, and put in the fixing bath. Messrs. Butcher supply powders for use in compounding the developer at the price of 1s. 6d. per packet of six, each sufficient for one tank full. Or a solution may be had, at the price of 2s. 3d., ready for dilution with water and sufficing to fill the tank ten times. The price of the tank itself is 35s.

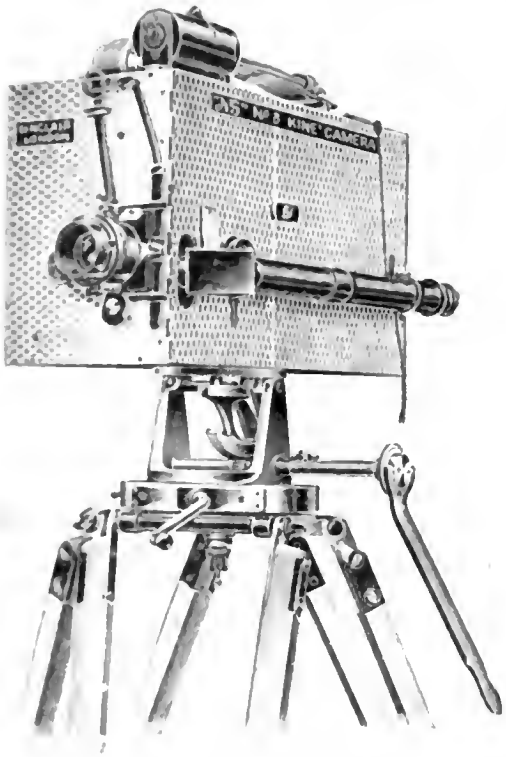
Fig. 3.

The N. S. Cinematograph Camera. Made by James A. Sinclair and Co., Ltd., 54, Haymarket, London, S.W.1.

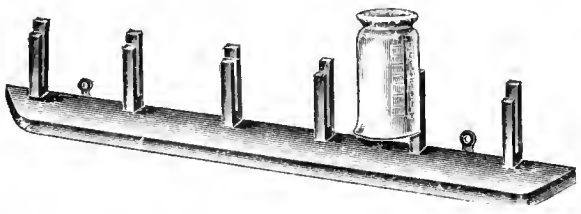
This camera for all descriptions of cinematograph negative making has been further improved by its designer, Mr. Arthur S. Newman, and now embodies a range of movements and conveniences beyond which it seems inconceivable that the cinematograph camera man can wish to go. We are afraid that no written description can do ample justice to the excellence of its design, but special emphasis may be laid upon some of its outstanding features. A chief one of these is the extreme ease of threading the film into the mechanism. The film boxes are placed side by side to the rear of the camera. The film is simply inserted from the full spool box and travels along a channel from which it is most expeditiously threaded through the gate. By means of the winding handle it is then conducted along a guiding channel to the take-up spool box, the whole operation occupying only a few seconds. Another feature is the very light running of the mechanism, making it possible to use the camera on a comparatively light tripod, so that the whole outfit (camera and tripod) comes within the weight of



32 lbs. By means of a special gearing the film can be moved in either direction by means of the winding handle without the shifting of any bands or pulleys. Moreover, the winding mechanism is provided with positive indicators at the rear of the camera whereby every single picture is denoted; that is to say, for trick effects the film can be turned on and exposed backwards over any given length, and exposure then resumed exactly at the section of the film at which the reverse exposure started. Similarly, the indicator allows of accurate track being kept in making "fading-out" and "fading-in" effects.

The arrangements for viewing the picture are most complete and efficient. The picture can be seen and focussed through an eye-piece mounted in one of the side doors of the camera; or this eye-piece may be fitted with a prism and tube by which the actual picture can be sighted from the operating position at the back of the camera. There is also direct-vision finder mounted on the camera top, and adjustable for lenses of different focus. The instrument also provides for the accurate insertion of masks without opening the camera. Both focussing and adjustment of the iris diaphragm are controlled by scales at the back; and a word should be said for the exceedingly reliable method of moving the lens in its mount, not by the helicoidal device of the ordinary focussing mount, which is subject to derangement by wear, but by a simple to-and-fro movement operated by a lever. The lens mounting likewise allows of objectives of any focal length being fitted, and being almost instantaneously interchangeable. Yet with all these movements the camera is small, measuring 14 × 5⅝ × 8 inches. Fitted with 2-inch *f*/3.5 Ross Xpres lens, its price is £250. The tripod designed for it and embodying a most perfect revolving and tilting top is sold at £31 10s.

A Graduate Drainer.—Messrs. Rycott & Dixon, 115, Balham Hill, London, S.W.12, send us one of the draining racks made by them for holding the photographer's glass graduates when the latter are not in use. As shown in the drawing, the rack consists of a series of pegs on which the graduate is loosely fixed in the inverted



position so that it does not become dirty from settlement of dust and cannot pick up chemicals from the work bench. Also the rack is made so that it can be screwed as a shelf to the wall, thus saving space on the work bench and at the same time providing a safe and accessible support for the glass measures. At present it is made to take six measures up to 20-oz. size, price 2s.

New Materials.

Zona Developing Paper. Made by Thomas Illingworth and Co., Ltd., Park Royal, Willesden Junction, London, N.W.10.

A quite new introduction of Messrs. Illingworth is a development paper of speed about a third that of the average gaslight paper, and similar, in its steady progress to full depth in the developer, to bromide paper. The new paper is made primarily for the purposes of portrait photographers, who usually have ample power of artificial light at their disposal, and to whom, therefore, the slower speed of the paper is a matter of small moment. A further notable feature, again of special interest to the maker of portraits, is the surface, or rather surfaces, of the paper. Two grades are made, one of so fine a matt that it can be fairly said that the effect is that of a plain paper uncoated with emulsion—in other words, the natural surface of the paper. The other grade has a slight sheen, but so slight that Messrs. Illingworth cannot bring themselves to call it "sheen," but only lustre; and we agree with them that the delicate touch of brilliance imparted to the prints made on this grade of the paper requires the less positive designation for its description. Actually the difference in the two surfaces is a very subtle one. We cannot recollect having had two distinct grades of paper between which the distinction was so fine; which goes to show the remarkable point of perfection to which the manufacture of printing papers has been brought in this matter of surface alone. At any rate, the photographer who must make beautiful prints will find a pleasure in either the matt or the lustre grade of Zona.

So far as the printing qualities of the papers are concerned, the results exhibit a very wide range of gradation, and the prints made with the M.Q. developer, which is recommended, are of excellent slightly warm black colour. It is a distinguishing mark of some of these slow papers that they respond to all the quality which is present in the negative, and at the same time possess a latitude with regard to exposure much greater than bromide paper or than the ordinary gaslight paper. Moreover, the comparatively leisurely manner in which the prints develop is more in accordance with the practice which professional photographers prefer than is the rapid, almost instantaneous, progress to full depth, such as is shown by many emulsions. We should add a word also on the admirable warm tones which are obtainable by toning either with liver of sulphur or with hypo-alum. Zona paper is made (in each surface) in white and cream. While perhaps the latter is most suitable for the warm-toned effects, some tones on the white paper are particularly striking. Also, Messrs. Illingworth manufacture the new product both in single and double weight, so that with these three variable factors—surface, tint and weight—there is a large range of papers to choose from, ample for the purposes of the professional photographer making, say, both large unmounted sketch portraits and quite small prints. The full list of grades is as follows:—5a, white "Lustre" matt single-weight; 5b, white "Lustre" matt double-weight; 6a, cream "Lustre" matt single-weight; 6b, cream "Lustre" matt double-weight; 7a, white plat matt single-weight; 7b, white plat matt double-weight; 8a, cream plat matt single-weight; 8b, cream plat matt double-weight.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Monday, April 18.

Cripplegate Phot. Soc. "One Man Show." H. E. Wood.
South London Phot. Soc. "Gum Printing." H. E. Gorfin.
Willesden Photographic Society. Discussion Evening Summer Outing Arrangements, etc.

Tuesday, April 19.

Royal Photographic Society. "From Camera to Cinema." A. Pereira.
Exeter Camera Club. "Dye Impression Printing." C. H. Stokes.
Manchester Amateur Phot. Soc. "The Illustrative Art of Gustave Doré." E. D. Rodway.
Rotherham Photographic Society. "An Art Process with Simple Control." H. A. Hill.
Scottish C.W.S.C.C. (Glasgow). Plate Development.
Sheffield Photographic Society. President's Evening.

Wednesday, April 20.

Croydon Camera Club. Display of Prints from Plates Exposed on the Easter Monday Outing.
Dennistoun Amateur Photographic Association. Jumble Sale. Photographic Apparatus.
Edinburgh Photographic Society. Lantern Slide Making.
Ilford Photographic Society. "Maldon." N. K. Jackson.
Partick Camera Club. "The After Treatment of Negatives." A. Dordan-Pyke.
Woodford Phot. Soc. Annual General Meeting.

Thursday, April 21.

Everton and District Phot. Soc. "Bromoil." The President.
Hammersmith (Hampshire House) Phot. Soc. Annual Exhibition.
Kryn and Lahy (Letchworth) Phot., etc., Soc. "Figure Studies."

Friday, April 22.

Bedford Camera Club. "Picturesque Devon." (Ladies' Night.)

Saturday, April 23.

Hammersmith (Hampshire House) Phot. Soc. Outing. Richmond to Strand-on-the-Green.
Scottish C.W.S.C.C. (Glasgow). Outing to Gleniffer Braes.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, April 12, the president, Dr. G. H. Rodman, in the chair.

The President declared open a house exhibition of prints, selected from the competition organised among overseas readers of the "Amateur Photographer," which will remain open for several weeks.

Mr. R. J. Trump, B.A., B.Sc., delivered a lecture on a shutterless continuous-feed cinematograph in which the rays from the customary optical-projection system pass on to a set of mirrors which are successively angled to the lens axis. Marginal rays from the light-source are thus reflected on paths which, in the absence of obstacles, would meet in the focus of axial rays, so that a constantly moving picture in the gate of the projector is kept stationary on the screen by the synchronised movement of reflectors and film. The physical obstacle of the projector is avoided by the use of a second reflector, but it is claimed for the system that despite the twice-repeated reflection, the light efficiency is 80 per cent. as compared with an alleged 50 per cent. of a shutter projector. Although, theoretically, a projector having a given lens and mirror wheel is suited for only one distance from the screen, it was stated that the practical performance at various distances was satisfactory.

Some discussion followed the reading of the paper, and different opinions of the sharpness of the projections were expressed by two speakers who had witnessed them.

The general technics of cinematography were next considered in a series of discursive notes by Mr. H. M. Lomas, who touched briefly on film storage, definition, development and on many other photographic matters from the cinematographic standpoint.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held April 4. Present: Messrs. E. D. Young, J. Campbell Harper, J. B. Johnston, Norman Thomson, J. Drummond Shiels, Fergusson, Laing, Moffat, and Melrose. Mr. E. D. Young (President) in the chair. An apology for absence was intimated from Mr. Swan Watson.

The Secretary read a letter which the President had received from a photographer in the south of England, congratulating in appreciative terms the Society in their efforts to maintain the prices of professional work and on their endeavour to combat the question of "free sittings." He stated that the practice in London of giving "free sittings" was carried on by professional photographers to an alarming extent, and tended in a great measure to reduce the business standing of professional photographers.

The Secretary read a letter from Mr. Claude Lauder resigning his membership of the Society, which was accepted with regret.

Mr. Johnston and Mr. Norman Thomson, the members of the Heriot-Watt Committee appointed by the Society for waiting upon Principal Lauris in connection with the institution of a class for practical chemistry as applied to photography and optics at the Heriot-Watt College next session, reported that they had a long interview with the Principal last week. They stated that the Principal seemed to be averse from the idea of starting a class for the above subjects for photographers only, and desired the inauguration of a national school of photography in Scotland to embrace all classes of photographers and process workers. The lack of funds, however, together with the uncertainty as to whether the Education Authority were to undertake the management of the Heriot-Watt College, prevented the possibility of this scheme being attained in the meantime. Mr. Drummond Shiels suggested that an effort should at once be made to get a trade class for photography started as early as possible, and that the Education Authority should be approached with a view of instituting a technical class. His view was that to wait until a national school of photography was inaugurated would be to shelve the matter indefinitely. It was accordingly resolved to approach Mr. McNally, of the Education Authority, after the ensuing election, and to ascertain if they were willing to consider the formation of a trade class for photography at the night schools. Mr. Johnston and Mr. Norman Thomson were thanked for their services and were discharged.

Mr. Moffat next submitted the report of the Committee on the minimum prices of commercial photography. He laid before the meeting a costing basis table showing the actual cost of one unmounted print in the various sizes, with a percentage of profit added. The minimum charge for the operator's time was fixed at 2s. 6d. per hour—one hour being the minimum charge. The meeting expressed their indebtedness to the Committee for the trouble which they had taken in the matter, and considered that the costing system basis was undoubtedly the proper system to work upon. The members desired time to consider the table, and the secretary was requested to furnish each member with a copy. The secretary was also requested to urge each member to be present at the next meeting of the society, when the matter would be fully considered and decided upon.

The secretary reported that at the last informal meeting the minimum prices of groups were considered, and it was recommended that the present minimum prices for groups be approved of, but no minimum prices were to be fixed for whole plates or smaller sizes, and this was agreed to. It was understood that the minimum prices were to be for one dozen copies.

The proposal to increase the membership of the Society was cordially received by the members, and Mr. Yerbury and Mr. Campbell Harper were appointed to call upon each professional photographer in Edinburgh who was not a member of the Society and invite him to the next meeting, which is to be held in the Victory Café on May 2, and endeavour to get him to join the Society.

The president intimated that at the next meeting of the Society new office-bearers fell to be elected. It was only right that members should meantime consider the claims of members who were most suitable for nomination. A vote of thanks to the chairman for his conduct in the chair concluded the meeting.

CROYDON CAMERA CLUB.

The good-natured Mr. L. J. Hibbert kindly filled a gap, caused by a fixture falling through, with a capital exposition on "Photo-Micrography." An imposing array of apparatus was on the table, with which some excellent photo-micrographs were secured. Wise in his generation, he never confuses the tyro by saying too much, and his clear explanation of the theory and working of the instruments shown proved him to be an adept in the teaching line. A most hearty vote of thanks was accorded him.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square, on Friday, April 8. There were present, among London members, Messrs. Marcus Adams, Angus Basil, Alexander Corbett, Alfred Ellis, W. E. Gray, Reginald Haines, George Hana, Richard N. Speaight, H. St. George, and F. G. Wakefield, and among country members, Messrs. Frank Brown (President), W. Illingworth, and W. H. Wedlake, with Mr. Lang Sims (Secretary).

Apologies for absence were received from Messrs. Chase, Dickinson, Lambert, Turner, Swan Watson, and Wheeler.

The Finance Committee submitted recommendations for payments amounting to £93 1s. The recommendations were approved.

The Secretary read the names of eighteen new members, and also reported two resignations, due to retirement from business.

The Chairman, in reference to a motion in his name which appeared on the agenda of the annual meeting, said that he had to apologise to the Council, on behalf of the Secretary and himself, for taking time by the forelock. It had been, he believed, the unanimous opinion of every member of the Council that the Association should be incorporated, but before any step could be taken in the matter it was necessary to introduce a motion to the annual general meeting, and as that took place a fortnight from that day, and it was necessary to give 14 days' notice of motion, there was no opportonity for submitting the form of motion to the Council first. The wording of the motion had been drafted by the Association's solicitor, and he understood that it was quite in order. As Mr. Illingworth was the first to introduce this subject, he thought that Mr. Illingworth should be associated with it at the annual general meeting as seconder. The motion was as follows:—

"That, having regard to the disadvantages of the present constitution of the Association, and with a view to it becoming a formal legal entity possessing legal rights, and with a view to the effective protection and indemnity of its officers and removing

impediments to its progress, and acquiring greater certainty in regard to its correct administration, government, and powers, it is resolved that the Council be authorised, at the expense of the Association, to register under the Companies Acts, 1908 and 1917, a new Association, not for profit and limited by guarantee, to be called the Professional Photographers' Association of Great Britain (Incorporated), and that by the constitution of such new Association the liability of members shall be limited to—

(*a*) A subscription of 10s. per annum, and

(*b*) A contribution to the assets of the new Association in the event of the same being wound up during the period of membership of each member or within one year afterwards for payment of the debts and liabilities of the Association contracted before the time at which such member ceases his membership, and of the costs, charges, and expenses of winding up the same, and for the adjustment of the rights of the contributories among themselves, such amount as may be required not exceeding 10s. per member.

"And that all the members of the existing Association shall be entitled to become members of such new Association when registered without payment of any further subscription until the expiration of the period for which their respective subscriptions have been paid to the present Association, and that upon the registration of the new Association the assets of the existing Professional Photographers' Association be transferred to such new Association.

"And that a Committee be elected from the Council of the existing Professional Photographers' Association of Great Britain with power to settle the Memorandum and Articles of Association embodying so far as practicable the objects and rules of the existing Association, and such further objects and rules as such Committee may be advised are desirable."

Mr. Wakefield asked what happened in the event of the Association desiring to raise the subscription.

The Chairman said that it would be necessary to apply to the Board of Trade.

Mr. Hana asked whether it had been considered that this was the most suitable form of incorporation.

The Chairman said that the solicitor had advised that this was the best form. It was not necessary to put the word "Limited" after it, as in the case of an ordinary trading corporation. He added that he had seen the solicitor, who had promised to attend the annual general meeting to answer any questions.

Mr. Illingworth thought this the best form for the Association. He desired to know what the solicitor's opinion was of the motion he (the speaker) had brought forward previously.

The Secretary said that it was from Mr. Illingworth's suggestion that the memorandum from Messrs. Hutchison and Cuff took its shape.

The Chairman, explaining further points, said that the articles of association had to be drawn up after the meeting had agreed to the prelimnary motion, and then the matter had to go to the Board of Trade. The drafting would come before them, most likely at the next Council meeting, for sanction. The stamp duties would be about £13, on the basis of a membership of 2,000.

Mr. Haines said that he thought the whole expenditure, including the stamp duties, which had been increased, and the solicitor's fees, would be well within £100.

The Council signified unanimous assent to the form of motion to be proposed by the Chairman and seconded by Mr. Illingworth at the annual general meeting.

Mr. Frank Brown said that the thanks of the Council were due to the Chairman, Mr. Alfred Ellis, and the Secretary, Mr. Lang Sims, for taking this matter up so energetically. He would like to propose a vote of thanks to them for their prompt action.

Mr. St. George seconded, and this was carried by acclamation.

The Secretary gave some account of the latest alterations in the Congress arrangements. A number of short papers were promised for Tuesday afternoon, in addition to one or two trade demonstrations. The visit to the Houses of Parliament, fixed for Wednesday morning, could not be undertaken, owing to the present restrictions. He had then thought of a visit to the Mint, but the parties of visitors allowed were too small in number to admit of the whole of the Congress members seeing it in a morning. Then he got into touch with Right Hon. the Lord Mayor of London, and had secured an invitation to the Guildhall. (Applause.) The Lord Mayor would receive the party (if circumstances would allow), and if he could not be present himself at the Guildhall, the whole of the members there would be officially received by Alderman Sir Lewis Newton in his stead. They would be taken over the building, and shown the various objects of interest. Thursday was devoted to the Kodak excursion (Euston Station, 10 minutes past 1 o'clock), and included in the programme was a Council picture and the usual group of the members.

It was agreed that, if possible, the visit to the Alhambra Theatre, on Sir William Jury's invitation, should take place on Wednesday afternoon and Friday morning, subject, of course, to the convenience of those who had issued the invitation.

Mr. Speaight thought that the retiring President should have an official vote of thanks from the Council. Accordingly he proposed, "That the thanks of the officers and Council of the Professional Photographers' Association be tendered to Mr. Frank Brown, President 1920-21, for the valuable services he has rendered to the Association during his year of office."

Mr. Adams seconded this proposition, and it was carried unanimously.

It was agreed that the resolution should be incorporated in a letter to Mr. Brown in script, on a framed piece of parchment, and handed to him at the annual dinner.

Some discussion took place on the arrangements in the event of a transport strike, and it was agreed that if there was a general strike an emergency Council meeting of London members should be called, the date and time to be left to the Chairman of Council. Mr. Speaight suggested that a final decision on this matter might be reached after the meeting of the Selecting Committee on the following Tuesday.

Mr. Adams reported that everything was going on satisfactorily for the annual Exhibition. Ninety packets had been received up to that day.

The Secretary read a letter from the Eagle Star and British Dominions Company, who said that they had had a total of 24 applications as the result of the announcement on the circulars. The company was now desirous that the Association should include life with their other assurances.

It was agreed to leave the consideration of this matter over to the next meeting of the Council.

After a sitting of three hours fifteen minutes, the business terminated.

News and Notes.

TUNBRIDGE WELLS PHOTOGRAPHIC SOCIETY.—An exhibition of old Japanese colour prints is being held at the club rooms from April 18 to 23. On April 20, at 3 p.m., and on April 23, at 8 p.m., a lecture on them will be delivered by their collector, Mr. Basil Stewart.

SECONDHAND APPARATUS.—Messrs. W. Watson & Sons, 313, High Holborn, London, W.C.1, send us an 8-page list of cameras, lenses, and some miscellaneous accessories which they are offering at greatly reduced prices. The list includes a number of their own admirable "Acme" field cameras and lenses by almost all the leading makers. The list is obtainable free on application.

MINIATURE FRAMES AND CASES.—Messrs. G. & E. Russell, Northfield Road, King's Norton, Birmingham, send us a descriptive illustrated list of their original designs of miniature cases in morocco, persian, or velvet calf leather, designed with the taste which characterises this firm's productions. The rims of gold-plated metal or antique, reeded or frosted silver, likewise mark the artistic craftsmanship displayed in these goods.

WESTMINSTER EXCHANGE LISTS.—The Westminster Photographic Exchange, 111, Oxford Street, London, W.1, and 110, Victoria Street, London, S.W.1, have just published three price lists, one of current photographic requisites, both apparatus and materials, at the present ruling prices and including a considerable number

of the firm's own specialties. This is a very excellent list for the amateur purchaser, and one which he can conveniently study before examining the goods themselves at one or other of the Westminster Exchange's depôts. The other two lists are of secondhand apparatus, cameras, lenses, enlargers, and, in fact, every description of apparatus in very great variety. The Westminster Exchange, which has a very sound reputation for dealing in goods of thoroughly reliable working quality, is evidently in the position of being able to save the purchaser a good deal of money if advantage is taken of the many bargains offered in these lists, any of which are obtainable free on application.

NEW METHOD OF EMBOSSING DIES.—At the Printing Trades Exhibition the Marshall Engraving Co., Ltd., are showing a new method of embossing, or, what might perhaps be considered a more accurate description, a new and inexpensive method of making dies for embossing. Hitherto the printer has had to procure an expensive metal die, then make his own counterpart before he can proceed with his work, but by this "New Method" embossing all the printer has to do is to send his design to the Marshall Engraving Co., Ltd., who will cut the die and counterpart and supply them ready for work within two days, and at about one-quarter of the cost of the ordinary metal die. There is no metal, no counterpart to make, no chemicals, no powder, and, what is most important, you can do the work on a light treadle press, and a further important point is you can have your machine ready for working in about five minutes after handling your dies. That these dies are thoroughly effective is proved by the fact that 100,000 impressions have been taken from one die, and it is still in use. Full particulars will be supplied by the Marshall Engraving Co., Ltd., 12/14, Farringdon Avenue, E.C.4.

Correspondence.

FORMALINE AND THE GELATINE FILM.

To the Editors.

Gentlemen,—Re the paragraph in the 1921 "B.J. Almanac," p. 366, "A Warning Against Formaline," I have used formaline every summer for the past ten years or more, and have not so far met with any objectionable after effects. In the heat of summer here—with all solutions and washing water anywhere between 90 and 100 deg. F.—it is the only thing I have found effective in keeping the film on the glass. Without it, the film simply runs off, or, in less extreme cases, develops that appearance resembling the grain of leather—"leathery film" I have heard it called. Perhaps the trouble described by your correspondent is due to other causes.

I should add that I use the formaline *after* fixing. I rinse under the tap and then immerse for about ten minutes in 10 per cent. solution of formaline and then wash.—Yours, etc.,

H. W. SMITH

O'Keefe and Regent Streets, South Brisbane,
Queensland, Australia.
February 24.

THE FOLLY OF CHEAPNESS.

To the Editors.

Gentlemen,—The lot of the average professional to-day is not a very happy one, and I have had some sympathy for him, but a recent event in our district leads me to believe that some workers do not make the most of their opportunities.

Last week there was unveiled in our parish church a most beautiful memorial stained glass window, and, as was to be expected, a local professional worker of good standing was soon after it; in fact, the unveiling ceremony was scarcely over before I saw him enter the church with his camera. I admired his enterprise, knowing of the demand for prints.

I am very much surprised, however, to find that his result—and a very excellent one—is being sold in all the local stationery shops in the form of postcards at 2d. each! Threepence would have been low enough in these days of high prices, and it is something of a mystery to me how excellent and real photographic postcards of particular local interest can be sold for 2d. No wonder complaints about bad business are heard when the profession throws away good chances of making an extra penny or two.—Yours faithfully,

EAST COAST.

AN APOLOGY.

To the Editors.

Gentlemen,—Having unwittingly infringed the patents of Messrs. Move-o-Graphs, Ltd., we are unable to supply the Movie Apparatus advertised in the "British Journal." At the request of Messrs. Move-o-Graphs, Ltd., we desire to apologise to them, as follows:—

"The Movie Photo Company, of 20, Cornhill, Bridgwater, hereby tender their apologies to Move-o-Graphs, Limited, of 60, Doughty Street, London, W.C.1, in respect to the advertisement in the 'British Journal of Photography' of April 1, and state that the apparatus offered was an infringement of the patents held by the said Move-o-Graphs, Limited."—Yours faithfully,

THE MOVIE PHOTO CO.

20, Cornhill, Bridgwater.
April 9.

STEREOSCOPIC RELIEF.

To the Editors.

Gentlemen,—Your correspondent, Mr. Tilney, has such a pleasant and lucid way of telling his experiences with the bewitched wallpaper of his bedroom that his gentle hint that we are not to attribute them to the D.T.'s is hardly necessary. As, however, his rather alarming visual aberrations may make his friends, and especially his women folk, somewhat anxious, and as he asks for an explanation of the phenomena, and as I happen to be one of those dry-as-dust individuals whose fate is to deal with the dull technical side of optics as a recreation (!), perhaps I may be permitted to endeavour to throw some light upon the matter. It would need a very clever person indeed to "explain" fully any right impression, or to discuss with any degree of finality the "actuality" or "reality" of the images he refers to, or to say whether they should be regarded as objective or subjective. These questions must be left to metaphysicians to fight over. But it may be said that the floating images he saw were just as real as any other images; that, optically speaking, they were produced in the same way as other images; but that his judgment as to size, distance and reality was prejudiced by his knowledge that they did not correspond to the external facts, and by their obviously artificial and unnatural character which caused them to disappear when he moved his head.

The phenomena Mr Tilney chronicles have been familiar to me since, as a child, I saw the roses on my bedroom wall suddenly become delightfully small and close together and waver beautifully in mid-space. What happens is that we have identical patterns, spread at regular distances from each other in all directions over a large area. Let us call three of these patterns A, B, and C, running from left to right as regards the eyes. It does not matter in what direction we take the three, provided the line joining them is parallel to the line joining the two eyes, i.e., that they are in the same plane as the eyes. If the head is horizontal on the pillow, then A, B, C must be vertically placed on the wall; if the head is only inclined the three must lie on a corresponding diagonal; if the head is upright, as when one stands, they must be horizontal. Now, suppose that we unconsciously squint a little, so that the left eye looks at B, while the right looks at A, then we have really converted the wallpaper into a big stereoscopic slide, and we are viewing it in such a way that the lines of sight to corresponding points cross each other and intersect in front of the slide. This brings the image nearer, and at the same time makes it smaller than the original. Anyone who cares to consult the terribly technical articles on this subject which I inflicted on your columns last year will see how

the image grows smaller and nearer as the points of intersection of the lines of sight approach the eyes. If we squint so that the left eye looks at C, while the right looks at A, we get a still smaller and nearer image. Having once got it we can let our eyes roam at will, or we can even move our head along the line A, B, C, or at right angles to it, but if we twist our head ever so slightly we break the charm, and are brought back to reality with a shock. Having discovered the secret and made it our own, we can,, by "playing about with it" (in the delightful phrase of Mr. Tilney), produce a wonderful variety of effects. I amused myself in this way for ten minutes in the interval of dressing this morning. A finger held before the face so as to come between each eye and the particular pattern it is looking at shows the real distance of the image.

The simple method of experimenting, which I used last year, was to take two slips of smooth paper, about 1¼ in. wide and fairly stiff. At one end of each slip I described a circle of 1 in. diameter. I then held one slip in each hand and treated the two circles as a stereoscopic slide, viewing them first directly, i.e., the left oriel with the left eye, and vice versa, and then squinting at them. Movement of the two slips towards or away from each other was in both cases attended with a marked change in the size and position of the image. This was sufficient to prove the absolute necessity for correct spacing of the prints where accuracy is required in the result.

It may be pointed out that a stereoscopic image is not necessarily three-dimensional. The stereoscopic image given by the wallpaper as a slide is simply another wallpaper—another flat surface—that is, if the patterns are really identical and equally spaced. The difference of plane noticed by Mr. Tilney between the vertical lines of the pattern and the flower sprigs may be due to a slight shift of the colour blocks in printing. The difference in colour might also have something to say to it. In my own case, when I examine a Michelin map the reds have an uncomfortable habit of floating above the blues and greens in consequence of the absence of colour correction in my glasses.

The question as to what is necessary in a photograph in order that an impression of stereoscopic relief may be produced in the mind of the observer is not one that I would care to ask, much less to answer. Messrs. Lumière have presumably tested their apparatus and obtained satisfactory results, and this would appear to decide the matter so far as they are concerned. But when a real object is viewed by the eyes there is a very definite difference in the image received by each eye; and the really urgent question for those who would like to see stereoscopic photography occupying the important place to which its wonderful capabilities entitle it is rather—what is necessary in order that the stereoscopic effect produced may be so accurate, so reliable, and so readily obtained, that the judgment of the observer is able without strain or hesitation to accept it as true and as exactly corresponding to the reality it represents.—Yours, etc.,

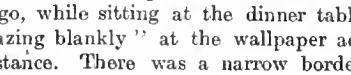
H. C. Browne.

Kingstown, Co. Dublin.
April 5.

To the Editors.

Gentlemen,—Referring to Mr. F. C. Tilney's letter, I am able to give an explanation of his experience with the wallpaper. About twenty years ago, while sitting at the dinner table in the kitchen, I was also "gazing blankly" at the wallpaper across the table at about 3 ft. distance. There was a narrow border at the bottom of the wallpaper about the same height as my eyes, the wall being panelled with wood beneath that to the floor.

The narrow border was about 4 in. wide, running horizontally across the wall; it had a repeating pattern such as this:—



I became conscious of the same effects as Mr. Tilney has described. I need not repeat them here. In less than a minute I was sure I had discovered, as far as I was concerned, what I had often looked for previously.

Here is the explanation in plain language. Some years previous I read an article in the "B.J." on how to obtain a stereoscopic effect without the aid of a stereoscope. In the article the writer said (so far as I can remember) that a sort of stereoscopic effect could be obtained by making the eyes squint inwardly, but this is not satisfactory and it is hurtful to the eyes. The proper way was to make your eyes diverge outwardly, but I could never understand how this could be done beyond the normal. While "gazing blankly" at the wallpaper or border slip I was, in fact, looking beyond the paper, i.e., my eyes were focussed at infinity.

Now, if you hold up your finger in front of your face and look at some distant object, say a hundred yards or so away, you will see two fingers with the tail of your eye, as it were. This is the whole secret.

The figures on the wall border scroll were all double, and each figure had moved just sufficiently to allow it to overlap on its neighbour and produce the effect Mr. Tilney speaks of. I tried the experiment on a stereoscopic slide and found the stereoscopic effect A1, only I may say that the picture looks smaller and the stereoscopic effect in some cases is slightly exaggerated.

Fix your eyes on some distant object, and, without altering the focus, slip a stereo slide in front of your eyes. You will then see four pictures instead of two, but with a little manœuvring you can quite easily get the two centre pictures to overlap and produce the same effect as a stereoscope.

What actually happens is simply this: You are looking at the right-hand picture with the right eye and the left picture with the left eye. You can easily prove this by first closing one eye, opening it again, and then closing the other.

Some people cannot see the right effect, even with a stereoscope; in fact, I have an assistant who sees two pictures instead of one, but I have not tried to find out the reason. For many years I could not see properly with binoculars, also seeing two pictures instead of one.

In practice it does not seem to matter much whether dissimilar views are used or not for distant views, but for near objects, such as a portrait bust, the effect appears to me quite flat unless the views are dissimilar.—Yours truly.

Norman Hunter.

The Studio, Port Glasgow.
April 4.

To the Editors.

Gentlemen,—I think that Mr. Tilney's difficulties are fully explained by the two letters given last week. I might add that when the pattern looks smaller than its actual size it is purely a mental effect due to squinting—actually, to the eye, the image is the normal size, but the brain has got so accustomed to associate converged vision with near objects that it cannot get rid of the habit. And when the eyes merge two objects in the wallpaper by gazing out on parallel axes the image, to the brain, appears bigger than normal and further away. Mr. Tilney's surprise at the butt joint being seen in duplicate is not justified; it is simply inevitable. Indeed, a quite useful test of whether a man is really seeing a stereo slide in the stereoscope is to ask, "How many pictures do you see?" If he is seeing properly he will see three separate pictures, the centre one of which alone is stereoscopic.

I had a curious experience of my own some weeks ago. I am not a teetotaller, and one day I caught myself with an empty wine glass at my lips, and looking through the bottom of the glass at the stem and foot I was surprised to see only the right-hand view of the stem. This was rather a facer, as I have been using both eyes on stereo views for over fifty years. Knowing that the left-hand view must be knocking about somewhere I put the glass again to my lips and shut the right eye. This, of course, brought up the left eye view. On opening the right eye again I got both views, but at the end of six or seven seconds the left eye view vanished again. I tried the experiment over and over again until I could hold both views together indefinitely, but it took me some minutes before I could see both right and left views of the stem without going through the preliminary shutting of the right eye. My subconscious brain evidently thinks it more convenient at such close quarters to work one eye only than to use both with such a great muscular effort of convergence.

Shortly after this I was showing a friend some slides, and after a bit found he was looking at them out of the stereoscope, insisting

that he could see them better so. I told him to first shut one eye and then the other to make sure that each eye could do its own proper work, and then to look with both eyes. In a minute or two he shouted, "Oh, I've got it, it's wonderful!" It was a miracle to him, and he was looking in vain at the stereoscope and then at the slide in and out of the stereoscope for some explanation of the miracle.

An oculist of my acquaintance tells me that this unconscious inhibition of one eye is quite a common defect, generally when looking at near objects, though sometimes it is only brought in when looking at distant objects. They put it down to laziness of the muscles used in convergent vision and don't so far bother much about it unless it is causing definite inconvenience. But if suspected, they have a quite simple test; they give the person a pair of spectacles, one lens of red and one lens of green glass, and then flash on the illuminated word "Friend," the alternate letters of which are red and green on opaque ground. If the eyes are not both in use the word appears as "F-i-n" or as "r e d."

I think that the inflexibility of most stereoscopes as regards inter-ocular separation is the cause of a great deal of difficulty in seeing slides properly. All stereoscopes ought to have the lens centres adjustable.—Yours truly, R. W. BLAKELEY.

Seedley Park Road, near Manchester.
April 11.

THE INVENTION OF SELF-TONING PAPER

To the Editors.

Gentlemen,—In an article by Mr. E. J. Wall, reprinted in your last issue, he ascribes the discovery of the self-toning principle to Mr. John Spiller. He may be quite right in doing so, but he does not give the date of Mr. Spiller's paper. [Mr. Wall, corrected, cited "Photographic News," Vol. 13, 1869, p. 401.—EDS. "B. J."] Reference is also made to a possible claim for Mr. Hennah. As to the latter, I may say that I was in Brighton in 1858, and greatly admired the work of Messrs. Hennah and Kent, whose studio was in the King's Road. Their specialty was whole-plate portraits on matt paper, but of quite a distinct character from the salted paper prints (then the alternative of albumen paper) of that time, they being generally either weak and foxy if untoned or grey and slaty if gold toned.

Hennah and Kent had a well-deserved reputation as being among the first, if not the first, photographers in the kingdom, and I remember reading in one of the Journals not long afterwards that people would come from all parts to Brighton to be photographed by them.

The formula for producing these brighter and more vigorous results was a well-kept secret, but some years later, when in business in Regent Street, I had on my staff a man who had been in the employ of Hennah and Kent, and he told me that Mr. Hennah used chloride of gold in the salting solution.

If Mr. Spiller made an independent discovery, and was the first to publish it, he certainly deserves full credit, whether or not Mr. Hennah previously practised the same method.

HALATION AND DEVELOPMENT.

To the Editors.

Gentlemen,—As the originator of the present run of correspondence under this heading I should like to say that I believe Mr. C. H. Mayes to be nearer the solving of the problem than any of the others who have taken part. You will remember that in your issue of April 8 I stated that I once exposed plates for a firm (who employed developing experts to develop all negatives sent home by their men operating abroad) who produced negatives quite free from halation, no matter how bad (halation-inviting) the subjects were. Although these expert developers worked more or less secretly, I do know that the developer they used was something like that advocated by Mr. Mayes. That is to say, stock percentage solutions of pyro and soda were used, but in what proportions I know not. I have made one experiment on the lines laid down by your correspondent, and I hope to make more—as I hope some more of your readers will—and it is just possible that the problem will be solved.

Mr. Mayes is also correct, I believe, in his statement concerning halation being minimised by prolonged development. In theory quick development should, of course, give less halation than prolonged development, and I fear too many of us have been led astray by thinking too much about theory and not enough about practice, there being a very wide gulf between them.

At a recent meeting of one of the suburban photographic societies there was shown an artificial light portrait study of remarkable quality, one in which a reading lamp was included. It was the kind of thing in which one expected to find halation, but not a trace of it was to be seen. This was sufficient to start the ever-green discussion on halation and its prevention. The taker of the portrait was not present to give details, but all the old hands present came to the conclusion that the negative must have been developed very rapidly, all present were, in fact, of the same opinion and authorities galore were quoted in support. At the close of the meeting, however, the taker of the portrait looked in and was at once asked by the chairman how he developed the negative. "Oh," he replied, "I used a very weak Azol developer and developed it for nearly two hours." Thus the house of cards built up by the advocates of very quick development tumbled down. In reply to further questions he said that he never thought about halation, it was the getting out of the details that concerned him.

The great difficulty in making experiments with halationary subjects is to get an object that we know will give halation, it being most difficult to produce where and when wanted. Until we can be really sure of producing it, or of selecting a subject we know will give it, it seems a little difficult to find a remedy for it. The only reliable test is that of cutting the exposed and undeveloped plate in half, and developing the two halves in a different manner. A leaded window of plain glass in a church appears to be the most suitable subject with which to experiment, but a more homely subject would be more convenient.—Yours faithfully,

GODFREY WILSON.

To the Editors.

Gentlemen,—I am also very interested in the correspondence on "Halation and Development," which has recently appeared in your columns. With over 30 years' experience in architectural photography, in which I have made hundreds of exposures on interiors, the question of minimising halation has always been with me. I entirely agree with your article of April 1, in which you advocate a "developer energetic enough to produce the necessary density before it has time to penetrate right through the film." I take it that energetic does not imply strong development. I always keep the pyro proportionately low and the accelerator fairly normal in quantity. Following this procedure, I found the method most effectual, when using fairly rapid plates (about H & D 270), well backed, the exposures on the ample side, to allow the shadow details to develop out easily, and then stopping development early, thereby obtaining negatives full of detail and soft in character. By these means I have obtained perfect immunity from halation under the most difficult conditions.

The double-coated variety, recommended by Mr. F. H. Evans, has, in my hands, proved superior to unbacked plates, but is also prone to halation under trying circumstances, which, no doubt, backing would obviate. As recently as last autumn I used some, and consider some of the drawbacks to their use to be the prolonged immersion in the extra strong hypo bath, extra washing required, and slow drying. Many years ago I used the "Sandell" multiple coated plates, and unfortunately many of the negatives are now useless, being badly stained, owing to the lack of knowledge of these characteristics, when they were made. I have seen some fine results on the new portrait films, which I hope to try shortly. I must admit I am somewhat sceptical as to their advantages over a well-backed and richly-coated glass plate for this class of work.—Yours faithfully,

EDGAR R. BULL.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

M. M.—We think you cannot do better than apply to the Premier Optical Co., 63, Bolton Road, Stratford, London, E.15.

P. C.—As you do not give us any idea of the intensifier used in either case, we can offer no suggestion, but if it was a mercury intensifier we think you must resign yourself to the fact that the stains cannot be removed.

R. B.—No doubt the book you refer to is "The Air Brush," by G. F. Stine, published a few months ago by "Abel's Weekly," 421, Caxton Building, Cleveland, Ohio, U.S.A, price 3 dols. 50. It is not on sale in this country, but you can get it by writing to Cleveland for it.

R. L.—The best cement for attaching anything to brass is gelatine dissolved in acetic acid. It is easily made, or may be purchased at the chemist's under the name of Kay's Coaguline. It might be well to give a thin coating to the brass and allow it to dry before proceeding to fix the blind.

P. W.—We have no doubt you could evaporate the hypo baths instead of throwing down the silver with liver, but it would be a very expensive process, and also the refiners prefer to have the silver sent to them in the form in which it is obtained by using the liver. Therefore, we do not think your suggestion is a practical one.

E. B.—There are no rules that we know of for the judging of competitions. If the prints are to be exhibited it is usual for the judge to mark each one as follows:—A. must be exhibited; B. may be exhibited; C. must not be exhibited, but, of course, that is only done when the exhibition aims to represent a certain standard of work.

W. M.—Any ordinary heavy sheet glass would be suitable, but for your purpose the finely-ribbed variety, known as Hartley's rolled plate, would answer best. This does not altogether stop the direct sunlight, but it diffuses it to a very considerable extent. It is in use in many studios. The ribbed side should of course be fixed inside or dirt will lodge in the grooves.

A. F.—An ordinary hydroquinone developer will give a considerably stronger print, particularly if you develop much darker than usual (too dark), and then bring the print back with weak Farmer's reducer, or better, weak iodine-cyanide reducer. If this does not give bright enough prints, about the only other method is that on p. 460 of the current "Almanac."

O. M.—We have never taken very kindly to the various meters which have been sold for ascertaining the time for printing on gaslight and bromide papers from various negatives. In our opinion a little test strip of paper is as quick and reliable as any other method, but we believe that about the best is Dawson's "Densitometer," which is, or was, supplied by Houghtons.

H. L.—It is rather a long story advising you on equipment for outdoor work, and perhaps the best help we can give is to refer you to an article on this subject in the "B.J." of June 11, 1920. The little book "Commercial Photography" which we publish contains a good deal of information on this same kind of work, and we think, perhaps, bears more directly on it than the "Photo-Miniatures."

E. G.—There is no objection whatever to your trading under the name, but if you do that you must register your business with the Registrar of Business Names, 39, Russell Square, London, W.C.1, at the cost, we think, of 10s., and comply with the regulations of such registered businesses. The chief of these is the name of the actual proprietor shall appear on note headings, invoices, and other business stationery.

G. G.—There is nothing the matter with your developing formula, although it contains rather more bromide than is usual for many papers, and that perhaps would account for the long time taken to develop. If we were you we should try making up a developer without bromide, and then adding, say, only 30 minims 10 per cent. bromide solution to each 20 ozs. That ought to be quite sufficient to keep the whites of a good paper pure during 4 or 5 minutes' development.

H. S.—We believe your friend is perfectly right in point of law. We had a paragraph on this very subject in our issue of February 25 last, page 105, in which it was pointed out that under the present Act, which came into force on June 30, 1912, unless the copyright is assigned to the purchaser when a negative is sold, the copyright remains in the hands of the seller. Of course this is an absurdity, and very likely was not intended in the drafting of the Act, but, at any rate, there it is in the Act, and in the absence of any judicial ruling the above is the only opinion that can be given. We refer you to our issue of February 25 for a further discussion of the matter.

C. K.—There is probably no better lens than the one you have, but, of course, the depth of focus with a 7-inch lens of *f*/4.5 aperture is not very great, particularly on near distances. This depth of focus has nothing to do with the construction of the lens, but only with the size of the aperture, and if you were to get another lens, of say *f*/6 or *f*/8 aperture, you would get just the same degree of depth as you would by stopping down your lens to one or other of these diaphragms. We do not think that you can benefit by making a change, unless, of course, the focussing scale is wrongly engraved, or the lens as a whole not correctly mounted. It might be worth your while to have the camera overhauled in these respects.

C. C.—You don't tell us much of the lighting of the building where the tablet is, but it is evident from the photograph that there are other windows to one side or the other, and perhaps behind the camera, light from which falls on the tablet and is reflected into the lens, giving the shadows in the photograph. About the only successful remedy for this is to fit up a kind of tunnel of muslin from the tablet to the camera, so that the light from all the windows is cut out and reaches the tablet as very diffused illumination. Very likely a screen on one side only would be sufficient, but that one cannot tell without seeing the place, or a plan of it. Exposure would, of course, be a good deal longer, but that need not be any objection.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3181. Vol. LXVIII. FRIDAY, APRIL 22, 1921. Price Fourpence.

Contents.

SUMMARY

The Congress of the Professional Photographers' Association opened on Monday last, when the President, Mr. Frank Brown, delivered an address. (P. 233.)

The exhibition of professional photography, held in connection with the Congress, is reviewed by Mr. F. C. Tilney on page 235. Mr. Tilney rejoices to observe a growing appreciation of straightforward lighting and effects.

It is to be regretted that the technical and commercial photographs are few in number, but a start has been made in organising this section which, no doubt, will receive a larger measure of support next year.

Mr. Raymond E. Crowther, in an article on page 231, describes some of the more recent work of Dr. Luppo-Cramer on desensitising with phenosafranine, and in particular the remarkable effect of the process upon the Watkins factor of the developer. Mr. Crowther has also made the remarkable observation that the transparent backing of Kodak plates acts as efficiently as a desensitiser of the emulsion as does a special safranine preparation. Since backing of this kind has been in use for several years, many users must have been desensitising without knowing it.

In a leading article we discuss a few practical points connected with the design and use of the reflex camera, which were suggested by two recent lectures at the Royal Photographic Society. (P. 230.)

Practical notes on the washing of prints are contained in an article by Mr. Arthur G. Willis on page 237.

At the Royal Photographic Society on Tuesday evening last Mr. A. Pereira delivered a lecture on the printing of cinematograph positive films. He showed the working of an actual film printer, and gave an exhibition of a film illustrating the methods employed by cinematograph printing firms. (P. 241.)

A simplified method of making half tone blocks of from 60 to 80 lines per inch is announced as in process of exploitation in America. (P. 229.)

The working methods in modern photo-lithography, processes of making paper stencils by photographic means, are among the "process" topics of "Photo-Mechanical Notes." (P. 238.)

In panchromatic photography the use of backed plates will obviate many of the difficulties of manipulation, the two sides of the plate being then readily distinguished by touch. (P. 230.)

With all the advantages of artificial light in the studio, the merits, both technical and hygienic, of daylight must not be overlooked. (P. 230.)

A close match of the colour of an original may be secured in an oil or Bromoil print by appropriate preparation of the ink. (P. 230.)

EX CATHEDRA.

Fair and Congress. Never have an exhibition of the photographic trade and the accompanying Congress of the P.P.A. been launched under such conditions of uncertainty as prevailed last Friday, when even the weather added an appropriate contribution of a snow storm to the threatened industrial discord. However, the inherent commonsense of the British nation emerged before the day was finished, and though reduced railway facilities have no doubt been a minor factor in lessening the attendance at the Congress of professional photographers from the provinces, it is evident that the Fair has never been so largely visited before. During the comings and goings of last Friday, while the fate of the nation hung in the balance, it was not to be expected people would flock in numbers to any exhibition. The advertisement programme carried out on that day has, however, amply proved its effectiveness in the shape of the attendances recorded when once the shadow of a national upheaval had been removed. In referring to these circumstances, it is fitting that we should take the opportunity of paying a tribute to the obstinate cheerfulness preserved at every hour of last week's days of crisis by Mr. Arthur C. Brookes, organiser of the exhibition. The quality of Mark Tapley has always been a distinguishing trait of our confrère of the "Photographic Dealer," but has never, so far as we know, had to endure such an acid test as that applied to it last week. We congratulate him, not on his luck, but on the not-to-be-beaten spirit in which he met what looked like being a most unpleasant blow of fate.

* * *

Simplified Half-Tone. We hear from a well-informed correspondent that a process is shortly being launched in the United States for the making of half-tone blocks according to a system by which the work may be done in a very much simpler manner than that which is the current practice in process establishments. The system, however, applies only to comparatively coarse blocks, namely, those of 60 to 80 lines per inch, but, nevertheless, even with this limitation, has a considerable field among newspapers, industrial companies and similar concerns requiring reproductions of photographs, etc. According to the particulars which have reached us a continuous-tone transparency is first made from the original negative, or from a copy negative of a print. This transparency is placed at the front end of a box, and at a fixed separation in front of it is placed a ruled screen, and in contact with this a flat process film. At the other end of the box there is a light-chamber with an electric bulb. In the partition separating the light-chamber from the interior of the printing box is fitted a variable opening or diaphragm. An exposure, which rarely exceeds two minutes, gives the desired half-tone negative. This is printed on copper by the usual fish-glue process, the technique of which has been simplified

for its use in this specific way. Results which have been produced are stated to be exceedingly good in vigour and long range of tone gradation; in fact, to a degree unusual in coarse screen work.

* * *

Backed Panchromatics. At last it appears that the average photographer has "discovered" the panchromatic plate. For many years it was used only by specialists and artistic amateurs, but it is now coming into everyday use for many classes of work. The improved sensitiveness of green has precluded the use of the green safelight (more safe than light), and consequently all manipulations have to be done in total darkness. This causes a serious risk of mishap at more than one stage, for the plate may either be put wrong way round in the slide or upside down in the developing dish. To avoid such mishaps it is a good plan to make a rule of using backed plates only. The backing is quite rough to the touch and it is hardly possible to make a mistake in working. Beyond the slight extra cost there is no disadvantage in using a backed plate, and with the great majority of subjects there is a distinct gain in quality, particularly in the rendering of light drapery. The backing is easily soluble and does not require any rubbing; as a rule it is entirely removed during development, and therefore does not darken the fixing bath.

* * *

Day and Electric. The facility of working and the wider choice of premises made possible by using one or other of the modern systems of electric lighting has had a tendency to blind many photographers to the very solid advantages of working by daylight, when it is possible to do so. Not the least of these is the effect on the health and nerves of the operator who is deprived during the greater part of the day of the beneficial effect of the sun's rays, and it cannot be expected that the sitter will not feel a certain amount of depression on leaving the brightness of, say, a seaside parade and walking into the subdued light of an electric studio. Many operating rooms which are now solely lighted by electricity have sufficient window space to allow of all, or nearly all, bust portraits and half lengths to be taken by daylight during certain hours, and for both hygienic and artistic reasons this course would seem desirable. In one drawing room studio which we have visited the electric light was installed at one end and during the day was used only for full lengths and groups, while all other work was done by the light of large French windows which opened upon a well-kept lawn; exceptionally fidgetty youngsters were often taken outside with the aid of a reflex.

* * *

Colours in Oil printing. As a rule oil printing and Bromoil are regarded only as media for artistic expression and the technical or commercial application of these processes is entirely overlooked. As a matter of fact, oil printing is practically identical with the process of making photo-litho transfers, and lends itself excellently to the reproduction of prints or engravings. The point to which we wish to call attention is the ease with which the colour of the original ink can be reproduced in the oil or Bromoil copy. There is a fairly good range of colours issued ready ground, and these may be combined to get intermediate tints, while further modifications may be obtained by adding more or less of the finely-ground dry colours to be obtained from any good artists' colourman. The dry powder should be worked up with a few drops of the oil medium before incorporating with the stock colour, and then well worked with a palette knife. For "straight" work it may be found more convenient to use a roller instead of a brush for pigmenting, either a fine leather or hard composition letterpress roller being suitable. As when working with the brush, a steady pressure with the roller puts on ink, while a light quick rolling clears up the whites.

SOME FEATURES OF THE REFLEX CAMERA IN PRINCIPLE AND PRACTICE.

THE meeting of the Royal Photographic Society, which a week or two ago was devoted to the reflex type of camera, provided incidentally, rather than deliberately, the occasion for some notes on the subject, which it may be well to publish at about the time at which presumably the official report of the proceedings will appear. The technics of the construction of a reflex camera were set forth by Mr. Arthur S. Newman. than whom there is no one we know better qualified to discuss the mechanics of photographic apparatus. Mr. Newman has a flair for making a mechanical device for doing anything that man can want done mechanically. If you asked him to make a machine for poking the fire or dealing a pack of cards, he would make it. It would cost a pretty penny, but it would continue in working order until the end of time. Of the constructional features of a reflex camera to which Mr. Newman referred, we wish to select one for a little further reference, because it relates to a matter on which the purchaser of such a camera is often in doubt. This is the movement of the mirror from its down position across the lens axis into the up position where it seals, or should seal, the camera box against entrance of light through the focussing screen. The importance of mechanically controlling this movement received special emphasis. It is of the highest importance to balance the movement of the shutter so that it does not come up against its seating with a bang, just in time to jar the camera the instant before exposure. At the same time it is necessary to move the mirror with the greatest practicable rapidity, in order to reduce to a minimum the interval between pressure on the release and exposure of the plate. Mr. Newman drew on the blackboard diagrams illustrating the mechanical devices for accomplishing both these things, and these details will probably be found to form the most interesting part of his discourse when published in the "Journal" of the Royal Photographic Society. The aim of the constructor is to move it slowly at first, then exceedingly quickly, and slowly to bring it to rest against its upper seating, all within a tenth or a twentieth of a second. Mr. Newman, however, did not refer to the type of reflex in which this operation is performed, not by an automatic mechanical device, but by "that clumsy tool, the human hand," as Mr. Bernard Shaw would say. The "release" on the outside of a reflex camera in which this principle is adopted is not actually a release at all, but a lever by which the mirror is swung upwards with a vigour and at a rate which depends upon the human operator. It can scarcely be pretended that a camera in which the mirror is moved in this way is comparable in uniformity or smoothness of action, or even in mere mirror-velocity, with one in which the mirror is moved mechanically. Mr. Newman did not attempt to draw comparisons. He has a habit of emphatic expression; perhaps he refrained. But it is not uncommon to find cameras with hand-raised mirrors ranked with those having mechanical raising, and even a superiority claimed for the former in certain respects. Thus it is stressed that the hand-raised mirror falls after exposure, whilst the other has to be put down, which is

true enough, but of no particular advantage, and, moreover, usually means that such a reflex camera cannot be used upside down at arm's length above one's head—a measure which occasionally is of great service. Against the variability and jar of a hand-raised mirror may be set its cheapness, but that is about all that can be said for it.

Mr. Newman was followed by Dr. Abrahams who, apparently from no fault of his own, found himself in a rather awkward position. Invited to speak on the use of a reflex camera, he appeared to think it necessary to reconcile his own expert practice in the high-speed photography of sporting subjects with the various advantages of the reflex type of camera. But he was dealing with two different things which cannot be reconciled in all respects, and the attempt to do so involved certain inconsistencies which it seems worth while to point out, for Dr. Abrahams, as spokesman for the reflex, evidently attempted merely to smooth away the differences. For example, it is a very reasonable objection to the reflex camera that it cannot be readily used at the eye level, but it is no answer to that objection to point out that Press photographers in using their ordinary folding focal-plane cameras go down on their knees in order to get a low view-point. The reflex user, who happens to want a higher view-point than that at waist level naturally does not care twopence for any reason which prompts Press photographers to assume an attitude of devotion. At the sacrifice of much of the visibility of the image on the focussing screen the reflex can be used at a higher level by means of a mirror fixed in an inclined position in the hood. The Graflex, and, we believe, other reflex cameras, have been fitted with an accessory mirror for this purpose, and, as we have already pointed out, the inverted reflex, if fitted with a spring-actuated mirror provides the facility of a higher view point than any other type of hand camera.

We are glad to be in agreement with Dr. Abrahams on the absurdity of the claim which is sometimes made that you can keep a rapidly-moving object in focus on the ground glass of a reflex camera by operating the head of the focussing pinion whilst a finger of the other hand is kept in readiness for release at the critical moment. We have never been able to find anybody who could use a reflex satisfactorily in this way, and, that being so, the motive for having the release on one side of the camera and the focussing pinion head on the other disappears. Yet Dr. Abrahams, if we understand him correctly, characterised the placing of release and pinion head on the same side of the camera as the act of a lunatic. But a long experience of various reflex cameras has convinced us that this is much the preferable construction, since the camera may be held firmly against the body with one hand, the other being then free, first for focussing on a pre-determined spot and then for release when the moving object is seen to arrive there in sharp focus. If the release is on one side and the focussing pinion head on the other there is necessarily an alternation between the hands as regards holding the camera in position, which makes it less easy to hold it firmly.

Plausibility in his rôle of protagonist of the reflex led Dr. Abrahams into some inconsistencies in the advice he gave on the use of a long-focus lens and of a swing-front on the reflex camera. He very rightly stressed the merit of a long-focus lens as regards correct drawing, but he did it as though there were some magic in a 12-inch focal length which did not reside in a 5-inch focal length. The half-truth of regarding focal length in this way instead of explaining that focal length simply determines scale of reproduction, whilst distance of view-point determines drawing, has, however, so often been stated that its spurious doctrine is, perhaps, immediately detected nowadays. The narrow-angle photographs shown by Dr. Abrahams so excellently demonstrated the value of the more distant view-point that it was difficult to conceive how their maker should assign so negligible an influence to the use of a lens angled from its position at right angles to the sensitive surface by means of a swinging lens-front. The latter is an optically wrong device which in certain circumstances can be very useful. But one effect which may often be produced by it, dependent on the lay of the subject, is to exaggerate the foreshortening which is exhibited in negatives taken at close quarters with a short-focus lens. Its bad effect is then additional to that of the near standpoint and of the same kind. If good drawing is a thing to be sought, the defect of the swing-front in this respect requires to be emphasised instead of being passed over as of problematical existence.

FURTHER NOTES ON DEVELOPMENT IN A BRIGHT LIGHT.

The recent publication in Germany of Dr. Lüppo Cramer's researches on desensitisation in book-form—a small volume which is one of the most important appearing since 1914, and which should be translated and so made generally available without delay—affords an appropriate opportunity of again referring to this subject. The process of desensitisation, despite the drawback attendant on the staining of the gelatine film, is rapidly becoming popular amongst amateurs who, as a class, are perhaps less conservative than their professional brethren. The professional worker will follow in due season and enjoy the comfort and other advantages of a really light dark-room illuminated by reflection from the ceiling with light passing through, for example, the Wratten "O" safelight. Amongst club amateurs the subject of removing the stain from desensitised plates is being constantly discussed, the consensus of opinion being that running water after an acid hardening-fixing bath is the most reliable method to employ. It will be frequently noticed that a desensitised plate will wash to a colourless stage, but on drying, a bluish-violet tint is developed. This appears to occur most frequently when the Desensitol has been used mixed with the developer, and the only remedy which I know is one of the chemical treatments recommended in the article in the "B.J." of January 7 last. As will be seen later, all staining of the gelatine can be obviated and the fastest of plates developed in comfort.

Ability to develop in bright light is not the only effect of desensitisation. In addition there are some remarkable effects which cannot fail to have been noticed by the photographer of catholic taste in developers. The most striking of these phenomena is perhaps that of the acceleration of the rate of development by hydroquinone. The slow-acting, low-Watkins-factor development characteristics of hydroquinone are too well known to necessitate comment. The presence of Desen-

sitol, either in the film as the result of preliminary bathing, or in the developing solution itself, causes this developer to behave like metol—the image as a whole flashes up in a few seconds and density is only obtainable on raising the factor some fourfold. The magnitude of the development disturbance in the case of hydroquinone appears to be considerable; with most of the other developers retardation of the reaction occurs, the amount of which varies considerably according to the desensitiser employed. With phenosafranine as the desensitiser, and leaving hydroquinone development out of consideration, the disturbance of development speed is, as far as the writer is aware, less than with any other of the compounds—developers or dyes—of which Lüppo-Cramer gives a list in the book already referred to. The majority of workers, however, will experience no inconvenience from this development effect, for when using Desensitol and an average M-Q developer there is practically no difference in either the time of appearance or the Watkins factor between a plate bathed in the dye solution and one simply soaked in water before development. With other developers this is not the case, as the following figures, in obtaining which a preliminary bath of 1 : 50 Desensitol was used, will clearly indicate :—

With pyro-soda time of appearance alters from 95 sec. to 60 sec.
factor ,, ,, 12 8

With amidol the alterations are 6 sec. to 14 sec., and 18 to 12 respectively. In short, desensitisation, except in the case of an M-Q developer, completely upsets all figures hitherto recommended for factorial development. This may appear perhaps to be a matter of but small moment, but when it is noted that for a given gamma the total time of development is radically altered it is evident that the matter is of practical importance even when Desensitol is used as the preliminary bath. "Even when Desensitol is used" needs emphasising, for there are at present on the market plates which are backed with red backing the dyes in which, in one case at least, are powerful desensitisers and which exert considerably more influence on the rate of development than either phenosafranine or Desensitol. Therefore more specific information on this point which I now give will perhaps be appreciated.

The most efficient desensitising backing I have so far met with is that designated "Transparent," with which Messrs. Kodak, Ltd., back all plates except the panchromatic. So active are the dyes used in this backing that if the backed plate be bathed, either in the dark or in a "safe" light for a minute and a half in water (1 oz. to a ¼ plate) the development may be subsequently conducted in the light which is usually employed when working with bromide papers. Even with an ultra-rapid plate no fog whatever appears during five minutes' development at 36 in. from an "O" safelight, the illuminant behind which is a 32 C.P. tungsten wire electric bulb. Although treating the plate in water before development leads to the greatest depression of sensitiveness, it is not necessary, as the developing solution itself rapidly dissolves the backing (a strip of glass cut from an old negative and placed under the negative at one end of the dish will ensure access of the developer to the backing) and desensitises the plate. The adhesives in the backing necessitate a somewhat longer time being devoted to the desensitisation than when a plain aqueous solution of dye is used, but one and a half minutes is quite sufficient to do all that is required. In this time, using water as the solvent of the backing, it was found that the speed of the plate was reduced to approximately 1/250th of its original value, and when using the developing solution as the solvent, to 1/200th of the original value. Whichever method of working be adopted the plate leaves the developer with its film unstained, and there is nothing in the finished negative, other than the complete absence of fog, to indicate that a desensitising bath has been used in its production. It must have been obvious to many that this "backing" variation of desensitisation would come into vogue, but that for several years self-desensitising plates were on the market, was not even suspected, although the statement that generally plates were nothing like so sensitive after they have been in the developer for a minute or two may be attributable to this fact. It may be noted, *en passant*, that the supply of dye in the backing is so liberal that the solution made by using 1 oz. of water per ¼ plate will effectively treat three or four ¼ plates. A source of supply of desensitising solution is thus ready to hand with every box of plates coated with transparent backing. The incidence of these backings may also be responsible for many of the conflicting statements which have been made regarding factorial development, for unless the backing is removed by means of a damp sponge before development, it may be safely stated that the Watkins factor may depend more on the vigour with which the dish is rocked than on the particular developer employed.

With regard to the action of desensitisers on the latent image, doubts have been expressed as to the accuracy of Lüppo-Cramer's statement that this entity suffers no destruction during desensitisation. As far as my experience goes, the statement is one of fact. It must not be forgotten that comparative tests in this work are not quite as simple as usual to carry out. The factors of wetting the plate before development and of considerable disturbance of the rate of development both enter into the matter, and their effects have to be eliminated before any conclusions are drawn as to destruction of the latent image. I believe that the suppression of tendency to fog in development allows of the fullest realisation of the speed of any emulsion—comparative experiments leave little doubt that the faintest shadow details can be developed more strongly on a desensitised plate than on one not so treated. In other words, the effective sensitiveness of the emulsion is enhanced—the H. and D. speed probably remaining unaltered—by desensitisation. The entire absence of fog further allows of the negative's being very cleanly intensified, a fact which should be of interest to astronomical photographers who are always demanding greater sensitiveness.

Before leaving the matter of self-desensitising plates, a note of warning should be added : the wrapping paper should never be allowed to come in contact with the face of the plate before exposure as there is a risk of the paper's being contaminated with some of the dye. It may be safely assumed that if the backing has been transferred to the paper it is sufficiently moist to desensitise the emulsion, with disastrous consequences in the subsequent exposure.

As was mentioned in the former article, the oxidation products of many developers are desensitisers. Amidol, for example, at a concentration of 1/2000 will reduce the sensitiveness of a plate to about 1/200th of its original value, even although the solution be freshly prepared and hence contains but a small proportion of oxidation product. It is significant that in the case of these products sulphites entirely prevent desensitisation. It is also remarkable that in the case of amidol the product which is formed by complete oxidation does not desensitise at all, but, on the contrary, induces red-sensitiveness. This product is essentially different in chemical constitution from those dyes which are used to prepare panchromatic plates, and although oxidised amidol as a red-sensitiser is of no practical value the knowledge of its action may stimulate research with similar compounds. Very little has been said with regard to the theory of desensitisation, and, indeed, up to the moment there is very little to say about it. Dr. Lüppo-Cramer has recently informed me that the action is one of oxidation, and he has promised particulars of some interesting confirmatory experiments at some future date. When these particulars come to hand they may, if circumstances permit, form the subject matter of a further short communication. In the meantime it behoves all who can do so to make themselves acquainted with the contents of the small book referred to at the beginning of this article, as it contains very much more information than can possibly be condensed into one or two articles of the present type.

RAYMOND E. CROWTHER.

THE P.P.A. CONGRESS.

The Congress of the Professional Photographers' Association at the Photographic Fair opened on Monday evening last with a reception of members by the President, Mr. Frank Brown, of Leicester, and members of the Council, following which a meeting was held, when Mr. Frank Brown presided, supported by Mr. Swan-Watson, president-elect; Mr. Lang Sims, secretary; and Mr. Alfred Ellis. A pleasant feature of the inauguration of the Congress was the presentation to Mrs. Frank Brown, who occupied a place on the platform by the side of her husband, of a bouquet of roses by Madame Yevondo.

The President delivered the address to the members which appears below, and followed it by an interesting series of notes, illustrated by lantern photographs, on the studios of notable professional photographers in different parts of the country.

On the proposition of Mr. Alfred Ellis, seconded by Mr. W. Illingworth, the hearty thanks of the meeting were accorded to the President for his address.

The Secretary announced that owing to the curtailment of the railway service as the result of the coal stoppage, the special train which was to have conveyed members to the Kodak works at Harrow on Thursday (yesterday) could not be run, but the Kodak Co. were making other arrangements, and the Secretary assured members that suitable arrangements would be made for their visit to Harrow.

The President's Address.

Ladies and Gentlemen,—It is with very great pleasure that I have the honour, as President of the P.P.A., of offering you a very hearty welcome to this, the sixth Congress held in connection with the Association. This welcome I offer not only for my own part, but on behalf of the Council who have worked most energetically and consistently in order to bring this Congress into such a position as will, I feel sure, make it of equal if not of greater importance and interest than any of its predecessors.

A reference to the programme will show the comprehensive nature of the labours of the week, and will bring more completely to your mind the ever-growing importance of the Congress, together with the gratifying expansion of our Association as a body. The very beneficial influence of such a convention as this cannot possibly be ignored; for here we have an annual rendezvous—on neutral ground—where we may meet without formality and restraint, and with that openness of mind that promotes good-fellowship, that breeds confidence and trust, the frank interchange of opinions, the promulgation of ideas, and the consequent widening of experience which results in a return to our daily labours with renewed zest and enjoyment.

The Exhibition of work by professional photographers in the room adjoining is becoming a more popular and, I may add, a more serious item connected with the Congress, being an illustration of a degree attainable by the professional portraitist, without unduly floundering in the ultra-artistic and sometimes freakish indulgences connected with some exhibitions—not necessarily of photographs—but still claimed by Art.

The trades exhibition is highly indicative of the zeal, enterprise, and inventive genius of our manufacturers, and will prove of immense value to the provincial photographer whose visits to the factories of the various firms exhibiting are of such rarity as to be practically non-existent. I trust the inventive genius of our manufacturers has discovered a method of lowering prices.

We have immense cause for congratulating ourselves on the fact that the threatened strike—the most formidable, I think, we have ever had to contemplate—has happily been modified. I have no doubt we should have got over most of the difficulties, although it is quite reasonable to presume that the attendance here would have been curtailed, and some slight disorganisation created by the partial interruption of the railway services. It is not my intention to dilate upon the subject of strikes, but as the present head of an association of business men I feel it my duty to protest against the possibility of a single trade being able to disorganise the whole community by any means, but particularly do I protest against sympathetic strikes. In my opinion, the sooner legislation is brought to bear upon this matter the better for the nation. When I say legislation I do not mean such as would penalise one class at the expense of another, but legislation such as will find the means of instituting compulsory arbitration, the verdicts of which would cover a certain reasonable period, and at the end of that period be reconsidered and readjusted if desirable or necessary. Meanwhile, there should be no stoppage of work.

It may, however, be that the adjustment of the coal question will take place by other means than arbitration. Continental powers have been for some time turning their attention to water-power for the generation of electricity, whereby cities can be supplied with light, heat, and motive forces, with the saving of millions of tons of coal. By hydro-electric power Ontario, Canada, is saving 6 million tons of fuel per annum. While this struggle is being carried on in England, other countries, formerly our customers, are finding means for dispensing with our greatest asset—coal—and in a few years colliers will probably be looking for other jobs. These observations may be looked upon as irrelevant, but I think otherwise. That such disturbances affect trade generally is perfectly understood by everyone, but I would suggest that our own profession is perhaps more severely chastised than most, being, as it is, a luxury; and luxuries are always first dispensed with. The slump, followed by this threatened strike, has hit many of the cheap photographers severely; and the depression in some quarters is positively acute.

The vital question, then, that naturally arises is, what can we do during these times of depression? and my answer is, economise to the utmost limit, see what can be done towards the improvement of your premises by careful personal application, and, above all, take steps to improve the quality of your work, and so be prepared for better times that sooner or later will surely appear.

Turning now to the everyday affairs of our Association, we have reason to congratulate ourselves to some considerable extent upon our position, both financially and numerically. I say "to some extent," because my hopes have been that with the expected settling down after the war we should have a grand influx of members, but I am rather disappointed to find that, although there certainly has been an accession of members, it has not been as great as I could have wished.

With increased membership comes improved finances, and, to put it the other way, with improved finances comes increased membership, owing to the fact that your Council can spend a certain amount upon the propaganda requisite to impress upon the outside, shall I say, professional photographer the necessity of subscribing to an Association designed for the protection of his own interests in particular, and those of his professional brethren generally. With this propaganda in view, the Council have for some time been deliberating upon a course that they hope will be effective in the enlargement of our membership to a very considerable extent.

The Association has now reached its twentieth year of existence, and I am happy to assert that, as it approaches its majority, it begins to feel the strength of manhood, so to speak, infused into its being. Its expansion becomes almost

daily more apparent, an expansion *proved* by its increasing responsibilities, and the ever widening scope of its activities.

At this juncture it will no doubt interest you to get some idea of what these responsibilities and activities consist, therefore it may not be inopportune to draw your attention firstly, to the announcement already in your hands relative to the incorporation of the Association as a company, limited by guarantee. This was proposed by Mr. W. Illingworth, of Northampton, and has now arrived at a stage where it awaits only the consent of the members before becoming an accomplished fact.

Considerable time, attention, and a very great deal of work by your Council and its sub-committees has been devoted to the consideration and practicability of creating an improved and more ambitious periodical to replace our P.P.A. Circular, which it has been proposed should be re-named "The Record." It has been felt for some time that a journal designed for the sole use and information of members of this Association is desirable, embodying with its present matter a much wider field of news and general information, together with a number of advertisements, the proceeds from which, it is believed, would assist materially in defraying the cost. This project has been examined most thoroughly in all its bearings, financial, editorial, and commercial—so thoroughly, in fact, as to cause the Council to decide to allow the matter to rest awhile on account of the many serious issues involved. But it will be brought up again for further deliberation in due course, I have no doubt, and the result remains to be seen.

Much has been written and said during the last twelve months relative to the training and education of our assistants, and your Council have been thoroughly alive to the importance of this question. Many schemes have been suggested, and talked over by them, some grandiose and idealistic in the extreme, others more sober and practicable; but, I regret to say, unattainable through insufficiency of funds. On this subject I can say little more at present than to advise our brethren to give to their assistants every facility and encouragement for attendance at Art classes connected with technical schools, now so general throughout the country. Art is the fundamental basis of photography, and to our assistants I would take the liberty of quoting the old saying, that "the gods help those who help themselves." It is to their own benefit that they should grasp every means of improvement obtainable, even at the sacrifice of a certain amount of pleasuro

Now I have so far alluded to these activities and responsibilities as those of the Association, but I think they should be called the activities, responsibilities and successes of the twenty-four or so of men who, from time to time, have constituted your Council, who have laboured persistently and consistently for these twenty years, and whose only reward has been the satisfaction of bringing the P.P.A. to its present state of usefulness and vitality.

I have been repeatedly asked the question: "Of what use is the Association to me? What does your Council do?" And in the public Press "A Member" asks: "Are the P.P.A. Council alive to their responsibilities of sagacious leadership?" I tell *you*, ladies and gentlemen, that this Association is full of vitality; it is alive. Its Council is alive, and where the interests of its members are threatened it will prove it is alive—and kicking!

What does the Council do? I will tell you. Most of its sittings are from 3 to 3½ hours' duration, exclusive of sub-committees. During that time full consideration is given to your affairs, sometimes individual, sometimes collective; and here let me acquaint you with a few of the subjects with which your Council has to deal:—Matters concerning copyright; faulty materials; goods damaged in transit; a firm advertising photographic sundries from which neither goods could be obtained nor money returned; breakages of negatives in the post; troubles with glass merchants; advisability, or otherwise, in certain cases, of insisting upon a charge for re-sittings; applications for assistance from members for help on resettlement after demobilisation; fire insurance inquiries; difficulties regarding electric installation; cost of supplying current; the non-supply of roll-films to professional photographers, and many others. I would like to give you two or three cases in detail now.

On one occasion the Secretary reported the case of a Hackney photographer whose shop front had been damaged by a motor car, and whom the insurance company had at first proposed to compensate to the extent of £10. On the photographer appealing for the help of the Association, our Secretary succeeded in getting the compensation raised to £27 10s., a goodly return for a 10s. subscription.

Another case related to a supply house which had failed to carry out its contracts to deliver goods carriage paid, and your Secretary proposed to enforce our member's rights in the matter. Only a small sum was at stake, but advertisers had to be taught that they must carry out their undertakings.

A second case discussed at the same Council meeting as the one preceding was against a newspaper, and was more contentious, but it was thought our member had a good fighting case, and should be supported. Both these cases were placed in our solicitor's hands.

Mr. F. S. Wakefield, a member of the Council, and an enterprising and successful photographer, makes his complaint very clear against trade enlarging firms who cater direct for the public, and expect at the same time to supply the professional. Frankly, the issue is in the photographer's own hands, and my advice is to combine by joining the P.P.A. Thus it is you will be able to meet combine *with* combine.

It will be scarcely necessary for me to remind you—I quote the words of our Secretary—how full the air has been of late of the word "combination." There is a possibility that trade combinations are affected with the idea of economic production. We therefore trust that the combines that have been brought about in photographic manufactories within the last two years will have the effect of cheapening materials all round. But where there is light there is usually shadow near by, and the shadow side in this case means a possibility of raising instead of decreasing the prices of commodities used by us. On the other hand, the prospect of keen foreign competition in the near future may have caused our manufacturers to pool their interests, and, with such an end in view, we cannot blame them. It is possible, therefore, that a strong organisation of professional photographers may be able to assist the manufacturers when it comes to foreign competition; but, anyway, a strong combination of our own is in a better position to give and take than is a large number of disunited units.

With respect to the question of trade enlarging, together with your Secretary I visited one of these firms, and, while being most courteously received, we were told that the conditions could not be altered; but at the same time this firm would be prepared to come into line if *other* firms doing the same thing would arrive at some understanding in the matter. It also pointed out that the professional *did* receive an extra discount, but we found that discount was practically a negligible quantity, and such an infinitesimal profit was of no use to any man who had to make his living by the sale of enlargements as part of his business. This is a matter requiring further discussion, and will not be allowed to remain as it at present stands.

An interesting letter during my year of office has been received from Mr. A. Cecil Coyne, the honorary secretary of the Professional Photographers' Association of South Africa (Natal Section), expressing the goodwill and appreciation of South African photographers for the work being done by the P.P.A., and also desiring that his Association should become affiliated to the P.P.A. Mr. Coyne stated that the desire of his Association was to strengthen the hands of the P.P.A. as far as possible, and to encourge their good work as the national and parent Association.

I have little more now to say, with the exception of a few words relative to the construction of your Council, which, on several occasions, has been questioned, but I am confident that it cannot be improved under existing conditions. The only alternative to the 12 London and 12 county councillors would be the election of representatives by branch associations affiliated to the P.P.A., or districts properly organised, who would probably pay the railway expenses incurred by their deputies when attending meetings of the Council. However, as up to the present branch associations do not seem to flourish, there is little prospect of any change; and change is, I believe, quite unnecessary. The London members work hard in your interests, so do the country men. The latter, as provincial photographers, are qualified to represent any and all country professionals, near or far, and they pay their own expenses. I would say that all are most worthy of your gratitude and your highest commendation.

In conclusion, I sincerely trust your visit to this Congress may be beneficial to your knowledge, and of immense utility in the conduct of your respective businesses; also that you may assist in bringing further members to an Association that will be an active combination, and able to meet other of our trade combinations on equal grounds, not necessarily as a fighting force, but as a body commanding encouragement and respect.

FRANK BROWN.

Studios and Their Effect on Sitters.

Following the above address, Mr. Frank Brown delivered a brief illustrated lecture, in which he dealt chiefly with the considerations to which importance is attached by the modern portrait photographer in the arrangement of his studio in respect to inducing a pleasant frame of mind, which has its outcome in an agreeable likeness. By the kindness of a number of friends he was able to show lantern photographs of a number of studios illustrating the gradual evolution from the old to the modern style, together with some of the portraits made in them. His first illustration was that of the Kent Lacey studios at Eastbourne, where, owing to the access of direct sunshine, conditions of work were more difficult than in many others. He showed examples of the very excellent portraiture made in the strong light of this studio, but expressed the opinion that there was a certain quality inseparable from the use of broken-up sunlight and different from that of work done in a studio which utilised only north or reflected light.

He then showed photographs of the studio of Mr. Halksworth Wheeler, Folkestone, pointing out the very small area of light employed by Mr. Wheeler in the production of his beautiful work. In this connection he recalled the advice to "concentrate your light" given to him many years ago by Mr. Walter Barnett—counsel which he had never forgotten.

As an example of the studio designed and furnished with the object of giving a homelike atmosphere to the room, he illustrated that of Miss Clara Cooper, Edgbaston, Birmingham, and showed several examples of the portraiture done in it. Another studio, also of a talented woman photographer, was that of Miss Ethel Eadon, of Sheffield, exhibiting more than a mere desire to escape from the old style.

A number of photographs were shown of the studio of Mr. Walter Scott, Bradford, which was designed by Mr. Drinkwater Butt. It extends over the top of three houses, has not any skylight, but a high sidelight of about 13 ft. for floor dimensions of about 40 ft. x 16 ft. Mr. Frank Brown quoted Mr. Scott's opinion, after several years' practice in it, that if he were rebuilding it he would not make any alterations. A feature of the furnishing of Mr. Scott's studio was the plain white panelled walls, of which effective use was made in the production of portraits in delicate scales of tones.

The President then showed a number of lantern slides illustrating his own Leicester studio, or rather studios, for the different parts of the building provide a very great range of lighting effects. The studio is situated in a garden, and the garden approach to it and the bright scene which it displayed in summer is constantly the occasion of sitters coming before the camera with an obvious sense of pleasure in their surroundings. He explained, and showed by examples of portraiture, that for some years past he had entirely given up the use of painted backgrounds, obtaining most naturalistic grounds from the walls, windows and angles of the studio, which is provided in one part with panelling and in another with tapestry wall covering, and thus affords endless opportunities for variety in the posing and lighting of sitters.

In conclusion, Mr. Frank Brown referred to the pioneer work in flashlight photography of his old friend Mr. Joseph Byron, of New York, whose reputation as a pioneer of flashlight portraiture, and particularly of stage scenes, was unique not only in the United States, where he had made his home for many years, but in other parts of the world. Mr. Byron, who is an Englishman, is now a very old man, and it gave him (the President) a great deal of pleasure to show some examples of the extraordinarily clever work which he did long before such results were achieved by other photographers.

EXHIBITION OF PROFESSIONAL PHOTOGRAPHY.

WHEN the Professional Photographers' Association displayed their work last year at the Photographic Fair, this journal took rather a resentful view of the nature of the work shown. The collection was to have proved that the portraiture of commercial studios could be as artistic as any that graced the walls of the amateurs' exhibitions. It sought to substantiate this contention by offering a large percentage of fancy subjects in which the facilities and resources were greater than those which came in the ordinary run of legitimate portraiture.

This year all that has been changed it is said. I learn that a vigorous selection resulted in the rejection of everything that smacked of the arty "stunt." It is only fair to say that the present show of work does not, in the main, promise more than any professional could offer to the average sitter. I am prepared, therefore, to accept the fact that the exquisite back-view of a nude damsel, called "The Casket" (27) is just as legitimate a portrait as the veriest *carte-de-visite* of our grandmother's days; only remarking that it has not yet been my happy fortune to receive such *intimate* "likenesses" from many a lady friend of mine from whom such a thing will be particularly acceptable. I must also believe that two more back-views of nudity, called "The Twins" (100), are now "the usual thing," as well as a profile silhouette of Miss Hylda Lewis, which, effective as it is, might, it seems to me, represent anybody.

Apart from these examples, there is no doubt whatever that the work shown is indeed legitimate, and the pleasing reflection is, that in spite of this fact, the display is every bit as artistic as the last. Theatrical subjects open a wide door for the entry of much freedom and novelty impossible in earlier years. Thus we have dancers and acrobats and a "Jazz Pierrot" (22) of the kind that exercise their seductions just outside the box-offices of "palaces," and "dromes." This

genus is indeed a large one, and includes an ingeniously combined group of *figurantes* under the title of "Karsavina—English Corps de Ballet" (8), which by the bye, is studio rather than stage-lit; and a lively "Petruchio" (52), of which the same may be said. But a real stage scene—a most difficult subject—appears in "The King's Bedchamber" (10), where the conventional lighting marks it at once for what it is, even to the terrible "property" window lit from behind. This is all managed with remarkable cleverness. It doesn't look true to life: it could not; but it will charm the stage-manager.

Perhaps the leading characteristic of portraiture to-day is its obvious effort to be interesting by adventitious means. Sitters are subjected to trick-lighting, to striking costume, to unusual posing, and other resources thought to be of service in lifting a work out of the common rut. The sitter's own personality, or psychology, as Mr. Marcus Adams would rightly describe it, does not seem to get enough serious attention. There is here a head of an old man quite simply taken, which is, in my humble view, one of the real gems of the show, because the face arrests you by its calm dignity and the fascination of its quiet yet penetrating glance, speaking of world-experience, life wisdom, human endurance. This is called "The Old Pedlar" (93): it looks as though it might be a portrait of a learned Rabbi, with its beard and serene expression. It is evident here that nothing has been lost by any of those post-exposure processes which have always been the obstacle to truly artistic portraiture. On the other hand, the inherent interest of the subject once seized, everything has been done to preserve it and give it full effect. Another old man's head, "A Portrait" (21), has character of a different kind, but little less admirable. He is smiling. The lighting and modelling is given with a robustness necessary to the subject, with a fine breadth in the shadows. "Lucien Pissarro, Esq." (96), is another case of a portrait relying solely upon a due rendering of the sitter's personality. He looks like an artist, not because of his hat and cape, his beard, and the gravity given to his eyes by his glasses, but because of the serene and intense expression that he wears. You would say, "a distinguished-looking gentleman." Surely a sitter and his friends would acclaim a portrait a successful one that gave such results.

Now take "An Artist" (41). Is there not a look about this as though the photographer had laid himself out to poke fun at the thing? The hat and tie are first rate as a rendering of that kind of "character" which just stops short of caricature. This is a fine thing in its way, I admit; but it represents the artist of fiction and drama. Take again "Mr. Joseph Holbrooke" (79); it has excellent style, a fine "pattern," and everything else in pose and treatment that would win it a place upon an exhibition wall; but does it look like a musical composer of some status? Has it not a deal too much "character"? In the case of "G. K. Chesterton" the paradoxical style of the sitter's writings seems ingeniously taken as a motive. He smiles either at us or with us, whilst his brows are puckered into a forbidding frown; humour tempering pessimistic philosophy.

There is no denying that ladies supply subject-matter that lends itself more amenably to art-for-art's sake; but the fact seems to be too often a ground for treating them always as though they were artists' models, hired for the purposes of picture-making. The portraiture, the psychology, seems to escape as the art comes in. There are some brilliant exceptions to this generality on these walls; for example, the fine "Mrs. G. F. Watts" (75), which is an unsophisticated, straight-forward likeness of delightful quality (perhaps a little marred by the too fierce high-light on the forehead). But quite a number of ladies' portraits aim, not at artistic portraiture, but at a kind of decorativeness or picturesqueness that leaves the humanity of the subject out of account.

"Miss Tessie Thomas" (11) is a beautiful work; and would have been more beautiful still had the light on the plane of the breast not been suppressed; "Liliane Gilbert" (61), displays most artistic lighting; "Miss Jean Chown" (71) is a fine bold work, with a fleshiness that holds the eye; but none of these can really be said to be portraiture in the strict sense of the word: they are pictures. We should like to possess them as pictures, perhaps, but we are not drawn to the subjects as persons whom it would be a privilege to know, and this is no doubt an injustice to each of them.

In the combined mother and child portraits the human element will not be kept out. It asserts itself in spite of artistry. The lines of "The late Mrs. Lionel Crane and Son" (26), are so excellently planned as almost to be obvious, especially as both figures are in profile; "The Hon. Mrs. Hope Morley and Children" (78) is a triumph of posing; but although in both these the art is not concealed it cannot rob the works of the charm of domesticity.

But, of course, professional photographers do not all have the same *clientèle*. Those who cater for theatrical people will find the decorative motive of more use to them than the psychological that aims at the human document. On these lines the development of the figure-study, such as that called "A Portrait Study" (85), is easily explained. Here we have not a sitter but a model—at least, so it would appear—the print is a large one, the costume shows anatomical details that have no place outside an artist's studio, the posing is highly "pictorial," the lighting unconventional, and—nobody denies it—the effect superb. But its title is a misnomer.

As a rule, the professional is at his best with children. He has a knack with them, and pictorial as he makes them, they are, generally speaking, delightfully childlike. "Child Portrait" (83) has the charm of a Lawrence. "The Lace Cap" (101) is a bold, strong presentment of a baby with a ball. "Child Study" (59), with just a touch of back-lighting, has been delightfully managed. There are too many to mention. All are good. The Bartolozzi red of "Olive" (4), treated in a circle, is very dainty.

I have always maintained that the professional who is worth his salt knows his composition well: so well, indeed, that he is often tempted to flout it. This surely has been done in the case of "The Turban" (9), where the lines all run down in a sort of stampede to the left. Here are the makings of a fine figure-study, the roundness and shapeliness of which has been lost by the unfortunate cutting off of the shoulder. With regard to tonal values, the professional is not on such sure ground. Enlargement plays him false, and a queer idea of strength frequently results in sootiness, as, for example, in "Field-Marshal Earl Haig" (87), which has the appearance of an excellent print accidentally dirtied. Sometimes that old fetish "sunning down" is responsible for defects which must be obvious to the most uninitiated. The sitter's book or newspaper is represented in such stygian gloom as to make reading impossible, especially as the face receives a full flood of concentrated light. As the sitter usually makes no attempt to read, it is thought perhaps that naturalism and rationalism is thus safeguarded.

This kind of "monkeying," with the light is the last remaining obsession of professional work which has to be shaken off. Why must a sitter's hands always look as though they had gloves on? I know the answer myself. The interest must be concentrated on the face. But this I maintain is an illogical method of concentrating interest. There are plenty of works here that show simplicity, or the avoidance of complex interest, by a rational lighting over the whole subject, which prevents high-toned spots from being antagonistically opposed by joining them up. Composition can be a far better help than "sunning down." The light parts can be massed sometimes; or they can be effectually shaded in the subject before exposure; a resource which gives in a legitimate way the result which sunning attempts with less perfect artistic effect.

Professional portraiture is now awakened to its best chances: there is no doubt about that; and amongst these exhibits there are evidences of subtle skill and fancy in designing. "Yvonne is Tired" (29) occurs to me, and "Portrait of a Child" (84). A pleasing fitness of treatment is seen in the mid-Victorian "Crinoline" (47), with its domed top, and border appropriately mid-Victorian also. But better than happy fancy are the signs of appreciation of the natural aspects of things; common-

place illumination, with its delights made plain, as in the masterly "William Harbutt" (94) (I am avoiding any joke about the *modelling*, splendid as it is). Here the beauty of flesh and textures are due entirely to a straight-forward explanatory lighting, and it is in this direction of ordinariness that the finest art lies. Putting the source of illumination at the back of the sitter or underneath or all round or on one side only, may give the jaded operator himself some little excitement of change and novelty; but he must remember that the sitters and the public are not always on the look out for something startling. They are not "used to it," like the eels that were being chopped up every day. They want something that shall make them feel pleased and proud of themselves; they don't care a toss for the photographer's reputation for art-resources. They will be pleased and proud if the portrait they get gives their likeness at its best, whilst it makes them appear to have brains and a heart and a conscience. The theatrical tendencies may produce profitable results in an art-for-art's sake direction, if the professions, both, do not lose their heads; but these tendencies are of no use at all in legitimate portraiture, which must first and foremost devote itself to taking *likenesses*, not decorative schemes; to rendering character, temperament, and personality; not legs and arms and backs as such.

The making of designs with sitters as motives; the evolving of tonal schemes with sitters as material, is by no means the same thing as taking a portrait with a keen sense of design, and a fine feeling for tone-values. Beauty must always be uppermost in the operator's mind, but he must seek it in those everyday conditions in which the sitter most easily recognises himself. There is plenty of it under these conditions. We most easily respond to sublimity in the commonplace; cataclysms only frighten us.

F. C. Tilney.

WASHING PRINTS.

There is no more unpopular operation in present-day photography than the washing of prints. Everyone, from the amateur rinsing a couple of P.O.P.'s in a soap dish, up to the trade house which has to free from hypo. some thousands of prints a day—everyone dislikes it.

Yet it is most essential that this should be done thoroughly. Modern investigation tends to lay greater stress on thorough fixation than on the total elimination of hypo., but the fact remains that no business can afford to scamp the later operation. A good deal of water and labour might be saved by some consideration of the facts involved; and it is the purpose of these notes to suggest some points worthy of attention.

Many professionals would gladly pay the added cost and use a hypo. eliminator, if they felt sure of the permanence of the prints so treated. Their distrust of chemical agents is only too well founded; it is true that the hypo. is perfectly destroyed by many commercial preparations, but it is not removed, and in the present state of our knowledge it is not possible to say that the compounds formed in its place are any more easy to remove or less harmful to the print than is the unchanged hypo.

Potassium permanganate is, as a matter of fact, by far the safest eliminator, because its strength and its action can be very accurately gauged by its colour; but even this is no substitute for water, and should only be used in exceptional circumstances.

There are three main ways in which we can utilise water for the washing of prints. In sinks or dishes, in mechanical washers, and in "sectional" washers. The second of these is not to be recommended. I have seen no mechanical washer in which any efficient method of separating the prints was used, and it is hard to conceive of such a method. And if prints stick together, it matters not how much water you use or how vigorously it is applied; it is impossible to remove all traces of hypo.

The sectional washers are better than this: their construction does preclude prints sticking together, but they have disadvantages. They take some time to fill and empty of prints; the same prints are always at the bottom of the batch, which is not good; and they hold only a limited number of prints.

On the whole, washing in tanks or sinks is undoubtedly the most generally efficient. It takes time and labour, but the results are most satisfactory when it is properly done. To be well washed, without a waste of water, prints should be treated as follows:—We will suppose there to be two sinks side by side; the prints are in sink A, face up. First, turn each print separately face down; then, draining each print as you pass it over, transfer them to sink B, face up. When all are over, turn each print face down again, and again transfer them to the other sink and fresh water.

To throw a lump of prints from one sink to another is *not* washing. Working on the above lines, turning each print in each bath of fresh water and draining at each time of transfer from sink to sink, ten, or at the most a dozen, changes will be quite sufficient. If you simply transfer them from sink to sink in a lump they will retain hypo. after fifty or more changes.

It is as well to test the last washing water for hypo. before putting the prints to dry. If this is done with permanganate the cost is practically nil, and it is an excellent safeguard against scamping, if unreliable labour is employed. Also it may show you that your washing goes on long after the hypo. is removed, and thus point the way to an economy of time and water.

There is one further point which I have found is not always well understood. Some papers—Satista, for example—we are told to wash for thirty minutes, the average time for bromides being an hour. I have known—at a reputable studio, too—a batch of Satistas and bromides placed in the same sinks for washing, and at the end of thirty minutes the Satistas were removed, oblivious of the fact that they must have been full of water hypo. impregnated by the surrounded bromides.

In districts where the water comes through chalk it is almost essential either to filter the water—a thankless job—or to wipe over the face of each print with a swab of cotton wool before placing them to dry.

In case anything in these notes may be taken as prejudicial to mechanical *plate* washers, I wish to say at once that some of these are most efficient. There is, of course, not the slightest risk of the plates striking together, and the ways in which the changes of water are effected are most reliable and competent to remove the hypo. in the least possible time.

Arthur G. Willis.

Butcher's Abridged Catalogue.—This 220-page list, just issued by Messrs. Butcher, Camera House, Farringdon Avenue, London, E.C.4, although much smaller in size than the bulky catalogues of pre-war days, describes the firm's innumerable supplies for amateur photography in adequate fulness and with illustrations in almost every instance. It contains particulars of the very latest introductions, such as the "Carbine" daylight development tank. Emphatically a list which the amateur worker should have at hand.

Photo-Mechanical Notes.

After Washing Bitumen.

THE by-product left after washing even 1 lb. of bitumen is somewhat considerable, and seems at first sight a great waste of good stuff. Anyone skilled in laboratory practice, and possessing the necessary apparatus, can recover the ether by distillation, and if distillation is not carried too far the thick residue is very useful as a cement when making wooden dishes or for repairing any that leak, this cement drying rapidly, and remaining when dry quite elastic, though hard.

Without recourse to distillation the solution makes a very fine black varnish for either wood or metal, and has a remarkably great covering power. It dries quickly and to a hard surface. Lantern announcement slides may be made which, when written on with a steel point, give clean-cut lines.—O. P.

Modern Photo-Lithography.

PROCESS engraving, photogravure and collotype are all standardised, so that little or nothing in the technics admit of improvements. Photo-lithography, on the other hand, is seething with activity, and most of the larger firms are putting down plant for negative making and for printing the image for the press, the older paper transfers being discarded as more or less obsolete.

Negatives up to 30 x 20 are being made with the aid of a step-and-repeat machine, containing from one dozen replicas to as many as twelve dozen, each replica of the subject being in perfect alignment and of the same density. These negatives can be utilised for single printing, or for the component negatives necessary for two, three, or any number of colours. These negatives, 30 x 20 inches, or smaller if desired, are used to print the ink image on plates 60 x 40, or smaller for direct and offset rotary machines or for flat-bed machines.

The metal plates are sensitised with bichromated albumen, and are dried on a whirler of the simplest construction. This plate, when the sensitive coating is dried, is laid face up on the bed of a large printing frame made in iron, and the negative laid upon this to register marks. Vacant spaces on the sensitive plate are then covered with thin tinfoil; thin card bearers disposed over this to equalise the space caused by the thickness of the glass negative, so as to prevent bending the thin metal plate.

Next a large frame carrying a sheet of plate-glass is lowered into position, covering the negative-covered sensitive plate; a clamp on each side presses this plate-glass in contact with rubber ridges running round the bed of the press, and then the necessary contact is obtained either by means of a small pump motor-driven by electric current or by a power vacuum. Innumerable Newton's rings show that the vacuum is complete, then the frame is swung from horizontal position to a vertical one, and exposure is made to a frame carrying eight or more mercury vapour tubes (some firms prefer arc lamps) for about five minutes.

Exposure finished, the frame is swung to the horizontal position, the plate-glass front wound up, and then the negative is moved over to the vacant portion of the frame. The image is adjusted to the register marks, again the tinfoil and card-bearers are put into position, the plate-glass front lowered, the vacuum secured, and another exposure made.

The sensitive plate then receives a coating of ink, applied either with a leather or composition roller, or by rubbing over with a pad charged with ink. Chalk litho ink thinned with turpentine is the favourite ink used. The image is developed in a large sink, the plate being deluged with water and the superfluous ink removed with wet cotton wool.

When developed and the edges all cleaned off, the plate goes to the pressman, and the photo-operator gets on with another.

If the printing plate is 60 x 40, and the negative 30 x 20, the image would be printed down four times and perfect register obtained.

Lithographers who have once begun to use printed-down plates on their machines quickly grasp the great advantage of this method over the older transfer and sticking-up methods. They are prepared for press in an abnormally shorter time, give far less trouble during the printing run, last from ten to twenty times the run, and hold the quality to the end.—W. T. WILKINSON.

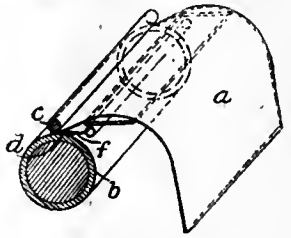
Photographic Stencils.

THE following stencil process invented by Lieut. Walters is very similar to the wax stencils used on the rotary duplicators, only in place of the wax film a gelatine or fish glue one is substituted, supported on butter muslin or some porous support. The film is made sensitive to light by the addition of bichromate of potash. Such a film is soluble in hot water, except when exposed to light, when it becomes insoluble. It will be seen that it is closely allied to the well-known carbon process.

The sensitive film is exposed to light under an ordinary ink tracing or manuscript written or drawn in an opaque ink; or it is possible to use a photographic positive of a drawing, type matter, or even a coarse screen half-tone positive. The parts that are protected from light, represented by the opaque portion of the positive, remain soluble and wash away; the parts under the transparent parts become insoluble. The sheet after exposure is developed in hot water, the result being a stencil of the original. Prints can be made either on a flat bed duplicator by the use of the inked roller or by means of the rotary cyclostyle 30 or 40 prints can be obtained per minute. Prints on all grades of paper can be secured, but with papers having a hard non-absorbent surface it is necessary to interleave each copy with blotting paper.

Photo-stencils can also be made by the ordinary methods of line etching. This zinc is coated with bichromated albumen and exposed under a photo-positive or drawing on tracing paper, or it can be drawn direct upon zinc, in an acid resisting varnish, but reversed from left to right. The zinc is etched in the same way as for ordinary line etching. It must be remembered that the drawing should be specially prepared for stencil work by adding supporting portions to prevent the centre of letters or designs falling out when etching.

LAYING TISSUE ON METAL. — According to a patent specification, No. 157,704, of H. Schulte, Frankenthal, Rheinpfalz, Germany, claims the following process :—In transferring a pigment paper or fabric on to the printing surface, the face of the paper or fabric



is moistened as it is being fed and pressed on to the surface. For this purpose, a jet of water *f* is directed on to the edge *d* formed between the printing surface *b* and the pigment paper or fabric *a* by the pressing roller *c*. The specification is open to inspection, but is not yet accepted.

FORTHCOMING EXHIBITIONS.

April 13 to 23.—Portsmouth Camera Club. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

April 15 to 23.—Professional Photographers' Association, at the Photographic Fair, Horticultural Hall, Westminster, S.W. Hon. Secretaries (Correspondent), Marcus Adams, 43, Dover Street, Piccadilly, London, W.1; (Exhibits), R. N. Speaight, 157, New Bond Street, London, W.1.

April 15 to 23.—Photographic Fair. Horticultural Hall, Westminster. Sec., Arthur C. Brookes, Sicilian House, Southampton Row, London, W.C.1.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs.

April 28 to 30.—Nottingham and Notts. Photographic Society. Particulars from the Hon. Secretary, A. Beeston, 103, Nottingham Road, Nottingham.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, March 29 to April 2.

COLOUR PHOTOGRAPHY.—No. 9,453. Cameras and projection apparatus for coloured photography. R. von Arx.

STEREOSCOPY.—No. 9,696. Attachment for taking stereoscopic pictures with any camera. W. B. Boothman.

RETOUCHING.—No. 9,639. Retouching screens. I. Boysen.

PHOTOGRAPHS.—No. 9,669. Photographs, and mounts therefor. G. R. Howley.

PRINTING APPARATUS.—No. 9,834. Photographic printing apparatus. Huebner-Bleistein Patents Co. and W. C. Huebner.

APPARATUS.—No. 9,836. Apparatus for positioning printing-plates of photographic printing apparatus. Huebner-Bleistein Patents Co. and W. C. Huebner.

CAMERAS.—No. 9,703. Photographic cameras. S. E. Neame.

LIGHT AND SOUND RECORDS.—Nos. 9,476, 9,634, 9,732. Process and apparatus for simultaneously reproducing optical images and sound waves photographically recorded on a film. E. Reisz.

CINEMATOGRAPHY.—No. 9,284. Cinema pictures, etc. S. Atkin.

CINEMATOGRAPHY.—No. 9,663. Projection of motion pictures. C. W. and W. Fennell.

CINEMATOGRAPHY.—No. 9,448. Cinematographic apparatus. G. W. Ford and H. G. Ponting.

Applications, April 4 to 9.—

TYPE PRODUCTION.—No. 10,218. Mechanism for photographic reproduction of type, etc. W. Broadbent.

TRANSMISSION OF PHOTOGRAPHS.—No. 10,233. Means for transmission and reception of photographs. M. J. Martin.

PROJECTION APPARATUS.—No. 10,088. Projection apparatus. L. Marzocchi.

CINEMATOGRAPHY.—No. 10,099. Shutter for bioscopes. R. W. Bond.

CINEMATOGRAPHY.—Nos. 9,852 and 10,004. Cinematographic pictures and apparatus for production thereof. S. H. Crocker.

CINEMATOGRAPHY.—No. 10,085. Spools and film holders for cinematograph films, etc. J. K. Douglas.

CINEMATOGRAPHY.—No. 10,379. Light control in cinematograph projectors. G. W. Ford and H. G. Ponting.

CINEMATOGRAPHY.—No. 10,380. Cinematograph projectors or cameras. G. W. Ford and H. G. Ponting.

CINEMATOGRAPHY.—No. 10,202. Solution for coating cinematograph films. A. Ott.

CINEMATOGRAPHY.—No. 10,203. Safety shutter for cinematograph machines. W. H. Penny.

CINEMATOGRAPHY.—No. 10,414. Cinematography. C. H. Verity.

COLOUR CINEMATOGRAPHY.—No. 10,062. Colour cinematography. Industrial Inventions, Ltd., and F. Perry.

COLOUR CINEMATOGRAPHY.—No. 9,993. Colour photography and/or cinematography. M. Martinez.

STEREOSCOPIC CINEMATOGRAPHY.—No. 9,992. Stereoscopic cinematography. M. Martinez.

CINEMATOGRAPH-PHONOGRAPH.—No. 10,501. Cinematographic apparatus for performance of musical films. C. Vische.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR CINEMATOGRAPHY.—No. 135,171. (November 9, 1918.) The invention is a symmetrically arranged printing machine for the production of coloured cinematograph films by successively copying the different series of colour components of a negative film ribbon upon one and the same picture surface on a positive film. The arrangement comprises on both sides of the light-exposure device two feeding sprockets for the negative ribbon, one of which is rotated intermittently by means of a Maltese cross while the other makes a continuous rotating movement. On both sides of the apparatus are two feeding sprockets for the movement of the positive ribbon and means for rotating the latter sprockets at one third the speed of the corresponding sprockets for the negative film; the feed sprockets situated on both sides of the printing gate are synchronously rotated from the same driving mechanism.

Oscillating levers support the ribbons at the printing gate, and there are means to clamp the ribbons between two plates; also to assure the exact coincidence of the negative and positive pictures.

A shaft is driven from a main shaft and fitted with arms which mesh with V-shaped notches in a disc fixed to the shaft of one of the guiding drums of the negative ribbon for the purpose of doing away with the lost motion of the wheel gearing, so as to enable that under all circumstances both ribbons may be registered by the pins.—Serge de Procoudine-Gorsky, Granstad, Konnerud, near Drammen, Norway, formerly of Petrograd, Russia.

The following complete specifications are open to public inspection before acceptance:—

REPRODUCTION PROCESS.—No. 160,739. Photographic reproduction by means of a phosphorescent medium. J. H. Christensen.

CINEMATOGRAPHY.—No. 160,749. Cinematographic apparatus. Jungst and Fabarius.

CINEMATOGRAPHY.—No. 160,797. Cinematograph and like apparatus. E. Coulon.

RETOUCHING.—No. 160,836. Retouching screens. I. Boysen.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

UFAG.—No. 383,896. Sensitised films for photography. Universum Film Aktiengesellschaft, Unter-den-Linden 56, Berlin, Germany, manufacturers. June 13, 1918.

VITTEX.—No. 408,883. Photographic printing paper and postcards. L. Gevaert and Compagnie, 23, Septe Straat, Vieux-Dieux, Belgium, manufacturers of photographic materials. October 19, 1920.

FAERIE CINEMA.—No. 409,603. Photographs. William Rampling Rose, 22, Bridge Street Row, Chester, Cheshire, manufacturer. November 10, 1920.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

SENSIBLA.—No. 408,884. Photographic chemicals, photographic plates, and photographic films. L. Gevaert and Compagnie, 23, Septe Straat, Vieux Dieux, Belgium, manufacturers of photographic materials.

TRADE MARKS REMOVED FROM REGISTER.

In the official language of the "Trade Marks Journal" the following trade marks have been "removed from the register through non-payment of renewal fees." Such non-payment is of course the method adopted by a firm having no further occasion for the use of a mark.

CATATYP.—No. 255,505. Neue Photographische Gesellschaft-Aktiengesellschaft. Registered in 1903 in class 1.

HYDRONAL.—No. 261,734. Dr. Luttke and Arndt. Registered in 1904 in class 1.

PERCHROMIN.—No. 265,703. Aktien-Gesellschaft für Anilin-Fabrikation. Registered in 1904 in class 1.

OMNAR.—No. 268,876. Rathenower Optische Industrie Anstalt Actien Gesellschaft. Registered in 1905 in class 8.

ENPEGOL.—Nos. 272,764-65. Neue Photographische Gesellschaft-Aktien Gesellschaft. Registered in 1905 in class 1.

BICHROMIN.—No. 274,051. Actien Gesellschaft für Anilin Fabrikation. Registered in 1905 in class 1.

CANVASETTE.—No. 286,781. Rotary Photographic Co., Ltd. Registered in 1906 in class 39.

AFPI.—No. 286,214. Emil Wünsche Actien Gesellschaft. Registered in 1906 in class 39.

WATALU.—No. 287,937. The Self-Developing Plate Co., Ltd. Registered in 1907 in class 1.

RAJAR.—No. 287,481.—Rajar, Ltd. Registered in 1907 in class 39.

RAPID ISOCHROM (label).—No. 288,397. Ilford, Ltd. Registered in 1907 in class 1.

TONNO.—No. 288,760. The British Gelatine Works, Ltd., Registered in 1907 in Class 1.

CUPIDO.—No. 286,122. Fabrik Photographischer Apparate auf Aktien vormals R. Hüttig und Sohn. Registered in 1907 in class 8.

PRESTO.—No. 290,186. O. Scholzig. Registered in 1907 in class 39.

RAINBOW.—No. 288,346. Geo. Nelson, Dale and Co., Ltd. Registered in 1907 in class 1.

REGISTRATIONS RENEWED.

OZOBROME.—No. 284,546. By Ozobrome, Ltd. Registered in 1906 in class 39.

VICTRIX.—No. 286,220. By Emil Wünsche Actien Gesellschaft Registered in 1906 in class 8.

Commercial & Legal Intelligence.

LEGAL NOTICES.—A first and final dividend of 5s. 6d. in the £ has been made in the case of Daniel Prodger, photographer, Fernbank, Eynsford, Kent, lately residing and carrying on business as C F. Treble, at 373, Brixton Road, S.W. The dividend is obtainable at the Official Receiver's Office, 280a, High Street, Rochester.

EASTMAN KODAK COMPANY.—The directors have declared the following extra dividends :—10 per cent. upon the common stock, payable on June 1 to stockholders of record on April 30; 5 per cent. upon the common stock, payable on July 1 to stockholders of record on May 31. The ordinary quarterly dividends of 2½ per cent. upon the outstanding common stock and of 1¾ per cent. upon the outstanding preferred stock will be paid as usual on July 1 to stockholders of record on May 31.

NEW COMPANIES.

VICTORIA PHARMACY, LTD.—This company was registered on April 12 with a capital of £400 in £1 shares. Objects : To carry on the business of opticians' and photographers' sundriesmen, etc. The subscribers (each with one share) are : Miss Violet G. Waplington, 70, Goldsmith St., Nottingham; H. S. Ball, 52, North Road, West Bridgford, Notts., pharmacist. Violet G. Waplington is permanent governing director. Qualification : £100. Registered office : 20, St. Ann's Street, Nottingham.

New Apparatus.

The Williamson VIII. Cinematograph Camera. Sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

SOME time ago we reviewed in these pages the two Williamson cinematograph cameras, the types IV. and VII. supplied at the prices of £28 and £42 respectively.

The third model, sold as the "Professional Camera, Type VIII.," is a full power instrument not only for straightforward topical work, but also for trick effects produced by reducing the speed of the film or reversing its direction. Moreover, the mechanical facilities are greater. The claw movement of the less expensive models is adopted, although in a somewhat modified form, but the gate is made instantly detachable for dusting, and the exposure punch operates on the edge of the film. One feature of the film mechanism is that the picture may be masked according to either the English or Continental standard. Also there is a mirror attachment by which the picture, when necessary, can be actually focussed up to the instant of exposure. The through sight finder has adjustments for making it accurate over a wide range of distances, and is provided with masks corresponding with lenses of different focal lengths.

As regards gearing, the instrument is provided with both standard and single-picture turn, and an indicator provided showing

the speed of turning on a scale ranging from 12 to 24. Reverse direction of the film is done very simply by taking the drive through a special pulley, and, in conclusion, a point which deserves to be emphasised perhaps more than any other, is that the whole mechanism is built and supported on its own framework, the case of the camera being simply an erection attached to this framework. Any warping or distortion of the case can have no effect on the relative positions of the parts of the mechanism. As showing the way in which little details have been studied, it may be mentioned that three studs are provided on the bottom of the camera in order to form a rigid three-point support for the instrument on the tripod head, and the handle on the camera case is set somewhat crosswise to the length in the position most convenient for carrying. It is evident that the whole instrument reflects an expert designer's care in every respect. The price of the outfit is £95.

ONTOSCOPE CAMERAS.—We are advised by Messrs. Robbins, Manistre (the London Camera Exchange), 2, Poultry, London, E.C.2, that the prices of the "Ontoscope" cameras, noticed a week or two ago, have been reduced by 10 per cent.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, APRIL 25

Bowes Park and Dist. Phot. Soc. "Pictorial Ideals." M. O. Dell.
Cripplegate Phot. Soc. "A Roam about Rome." W. Sanderson.
Willesden Photographic Society. Annual General Meeting.

TUESDAY, APRIL 26.

Exeter C.C. "Amateur Photographer" Prize Lantern Slides.
Leith Amateur Photographic Association. "Photography: Its Present-day Importance and Power." A. Dordan-Pyke.
Manchester Amateur Phot. Soc. Show of Prints. L. & C.P.U. Folio.
Portsmouth Camera Club. General Request Night. Ten Minutes' Lectures.
Walthamstow and District Phot. Soc. "Second Chat on Pictorial Photography."

WEDNESDAY, APRIL 27.

Borough Polytechnic Phot. Soc. Rummage Sale.
Ilford Photographic Society. Annual General Meeting.
Partick Camera Club. Annual Meeting.
Photo-micrographic Society. Members' Evening.

THURSDAY, APRIL 28

Gateshead and District Camera Club. "Amateur Photographer" Prize Lantern Slides.
Hammersmith (Hampshire House) Photographic Society. "A Ramble in the English Lake District." A. J. Linford, B.Sc.
Kryn and Lahy (Letchworth) Phot., etc., Soc. 1917 Competition Prints, R.P.S.
Kinning Park Co-op. Soc. C.C. "Colour Screens." R.A. Burr.

FRIDAY, APRIL 29.

Bedford Camera Club. General Meeting.

SATURDAY, APRIL 30.

Kinning Park Co-op. Soc. C.C. Outing—Milngavie to Blanefield.
Manchester Amateur Phot. Soc. Outing to Stalybridge—Walker Wood Reservoirs, North Britain, Shaw Moor and Stalybridge.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, April 19 the president, Dr. G. H. Rodman, in the chair.

The President drew special attention to the fact, which he considered to be an event in the history of the Society, that the paper which they were to hear read that evening would be illustrated by the projection of a cinematograph film. It was the first occasion on which the cinematograph projector had been used in the Society's lecture room, and he looked forward to other communications being illustrated from time to time in this manner.

Mr. A. Pereira delivered a lecture, "From Camera to Cinema," dealing with the printing and preparation for exhibition of cinematograph films. He exhibited, in actual working, a film printer, and demonstrated its mechanism, and proceeded to describe the appliances by which the film was tank-developed, fixed, washed, toned or tinted (or both) and dried. In cinematograph practice the standard developer was metol-hydroquinone containing a large proportion of hydroquinone. For toning, the copper toner of Mr. W. B. Ferguson was very largely used. Methods of dye-toning, such as those of Ives, were much more largely used in America than here at the present time. While the results possessed a transparency and brilliance which were not yielded by the methods of toning with metal salts, the dye toning processes required more expert supervision, and on that account had no doubt been slower in coming into general use.

Mr. Pereira then exhibited a film showing the actual processes he had described. It covered the whole process of producing the positive film. He also exhibited a film of a mirage in an African desert, the projected pictures showing with astonishing clearness a panorama of sea coast many miles away from the scene of the photograph.

In the discussion which followed, Mr. Colin M. Williamson asked for the lecturer's opinion on the origin of the dust which collected on sensitive films during printing.

Mr. Pereira briefly described experiments he had made which indicated that the greater proportion of the dust consisted of gelatine emulsion. The dust evidently contained a proportion of celluloid, but not more, he should think, than one part in eight.

Mr. Williamson referred to systems of printing mechanism, and suggested that a method of printing by optical projection was one which was deserving of attention as a means of avoiding many of the difficulties which occurred in the contact handling of the cinematograph negative and positive film.

In reply to a question by Mr. King, Mr. Pereira said that on the whole, he thought the four-punch type of perforator was the most satisfactory in practice.

On the proposition of the Chairman a most hearty vote of thanks was signified by acclamation to Mr. Pereira for a highly informative lecture, and for the very great trouble which he had taken in providing the exhibits of equipment and the projecting machine.

News and Notes.

A GRADUATE DRAINER. Messrs. Rycott and Dixon inform us, in reference to the notice last week of their draining rack for glass measures, that Messrs. Kodak, Ltd., are the sole wholesale agents for the supply of these to chemists and professional photographers.

HOUGHTONS' BULLETIN for professional photographers describes in its current issue reductions in the prices of plate-sunk mounts and negative bags and envelopes, and gives particulars of some items of professional equipment, such as paper storage boxes trimming desks and cascade washers.

NOTICE TO DEALERS. Messrs. Jonathan Fallowfield advise us that three pairs of Kershaw prism binoculars, X 6, engraved "Fallowfield, London," and numbered 1160, 1163, and 1164, were taken from their premises last week. If the instruments are offered to any dealer, the latter is requested to take such steps as may be necessary to detain the person offering them.

THE GENERAL ELECTRIC COMPANY announce the removal of their stores and offices to the new building, Kingsway, London, W.C.2, in which, after very great delay occasioned by the war, their many activities are to be centralised in one large building. Their address is Magnet House, situated at the corner of Kemble Street and Kingsway, and occupying a site of large frontage on the latter thoroughfare.

MR. ROBERT BALLANTINE, 103½, St. Vincent Street, Glasgow, has just issued a 32 page price list of second-hand apparatus, any items of which are offered on seven days' approval against remittance. The cameras, lenses, etc., in this list are all those of a high grade, and Mr. Ballantine informs us that all goods are examined and passed by himself personally before being sent out. A copy of the list will gladly be sent on receipt of a postcard.

TORONTO CAMERA CLUB.—The 30th annual salon of the Toronto Camera Club will be held from August 27 to September 10, again as part of the Canadian National Exhibition. Our Canadian friends will be very pleased to receive once more entries of pictorial work from those in the Mother Country. The prospectus and entry form are obtainable from the secretary of the exhibition committee, Mr. J. R. Lisson, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

THE ES OF MEES. A facetious correspondent, who is an admirer of the well-known physicist, Dr. C. E. K. Mees, Director of the Research Laboratory of the Eastman Kodak Company, writes to ask "Photo Era" whether Dr. Mees was born in the shadow of the Eastman Kodak Company, because he assumes that his middle initials stand for Eastman Kodak. Although this is a pleasantry at which Dr. Mees will smile, it may, nevertheless, be stated that in the Meesian expression E. K. is a constant denoting Edward Kenneth.

MESSRS. WARREN JEPSON AND CO., the well-known Leeds firm of enlargers and colourists, are exhibitors at the Photographic Fair, whose display, unfortunately, we were unable to include in our series of advance notices last week. We were not aware, until receiving the published catalogue of the Fair, that Messrs. Warren Jepson had a stand there, but we are glad to take this opportunity of directing visitors to this firm's exhibit (Stand No. 51), which will be found near the corner of the hall to the right of the entrance. Messrs. Warren Jepson are showing some exceedingly tasteful examples of enlargements in monochrome and colour, miniatures and commercial photographs.

AUTOTYPE COLOUR CHART.—The Autotype Company have just issued a handsome booklet of artistically mounted prints showing the 32 varieties in which Autotype carbon tissue is made. These include some colours which have not hitherto been shown on the firm's charts. The album is obtainable at the price of 2s. post free. The company has also just published a revised list of its manufactures for the carbon process, including tissues, transfer papers and the necessary chemical preparations. This list is obtainable free on application to 74, New Oxford Street, London, W.C.1.

GEVAERT PLATES AND PAPERS.—Messrs. Gevaert, Ltd., send us a circular of reduced prices of their plates and papers, according to which a dozen quarter-plates are now priced at 2s. 7d.; half-plates. 5s. 8d., and whole-plates, 10s. 11d. The retail price of Gevaert P.O.P. is now 31s. per quire of sheets 24½ × 17 inches, or 12s. per gross of 6 × 4¼ pieces. Net prices of postcards are 54s. per thousand for bromide, gaslight, and P.O.P.; 49s. per thousand for a "professional" grade of bromide, and 60s. per thousand for self-toning, with a reduction for quantities up to 5,000, except in the case of self-toning.

VEST-POCKET PORTRAITS.—If anyone requires a demonstration of the effective use which can be made of the vest-pocket camera he cannot do better than obtain a little book of reproductions of portraits of the players in "The Beggar's Opera," which has just been published at the price of half-a-crown by Mr. Alan Trotter, 36, Ladbroke Square, London, W.11. The 24 portraits were all taken in the dressing rooms at the Lyric Theatre, Hammersmith, by Mr. Trotter with a Vest-Pocket Kodak. While perhaps one or two of them are poor photographically, most of them are technically and pictorially of such fine quality that anyone turning over the pages would assume that they were made with the customary resources of a studio as regards apparatus.

LENSES FOR AERIAL PHOTOGRAPHY.—Messrs. Taylor, Taylor and Hobson send us a reprint of the paper by Mr. W. B. Appleton, read before the Royal Photographic Society in 1919, and describing the firm's improvements in the design of lenses for aerial photography. The paper is interesting for its record of this contribution to the photographic effort in the war, and, moreover, may be commended to the student of optics for the diagrams illustrating the nature of aberrations of oblique rays such as astigmatism and coma. We have no doubt that Messrs. Taylor, Taylor and Hobson will be pleased to send a copy to anyone applying to them at Stoughton Street Works, Leicester.

THE IMPERIAL HANDBOOK.—The 1921 edition of the ever-welcome "Handbook," issued by the Imperial Dry Plate Company, is as full as in previous years of articles and contributions of interest to the amateur worker. The contents lead off with a paper on "High Key Portraiture." Although not ascribed to them, it is evidently the work of Mr. and Mrs. Cadby. The delicate studies against white backgrounds are characteristically theirs, and if one were in any doubt, there is their portrait of Mr. Joseph Conrad. Similarly, we would venture to say that Mr. W. Thomas discourses on other pages of the opportunities for pictorial photography on the sea coast. There is a great fund of practical information in these and in other contributions which deal with orthochromatic photography, exposure for various subjects, the kind of negative required for different printing processes and photography at the Zoo. The many illustrations add to the attractiveness of the publication, a copy of which will be sent to anyone on application to the Imperial Company, Cricklewood, London, N.W.2.

COOKE LENSES.—Messrs. Taylor, Taylor and Hobson have just issued a new and revised edition of their catalogue of Cooke lenses, a publication necessitated by their recent introduction of a number of new types of construction. Among these are lenses for cinema taking and projection, and for astronomical photography of the large apertures of *f*/3.1. These are made in a series of focal lengths from 1 5-8th to 5 inches, the latter covering a plate 2¼ × 2¼. Messrs Taylor, Taylor and Hobson have also in course of construction lenses of 2, 3, 4, and 5 inches focal length of apertures as large as *f*/2.5, *f*/2, and *f*/1.9. Manufacture is not sufficiently advanced for these ultra-fast objectives to be listed in detail, but further information respecting them will be sent on request. The new catalogue also describes a convertible *f*/4.5 lens of new design made in two focal lengths of 6½ and 7½ inches. The front combination supplies a single lens of *f*/11 aperture, and the back element one of *f*/8 aperture, the focal length of the back half lens being thus somewhat shorter than the front element. Particulars are also given of the new Cooke telephoto lens obtainable in a series of focal lengths from 8½ to 20 inches of *f*/5.8 aperture, and requiring a camera extension approximately 60 per cent. of the focal length. Having terminated an arrangement with Messrs. Penrose for the sole distribution by the latter firm of Cooke process lenses, Messrs. Taylor, Taylor and Hobson now include these latter in their price list since they are free to sell them direct. The catalogue usefully makes special reference to the fact that in the choice of an *f*/4.5 lens the amateur purchaser should not cut the focal length too fine, since with these ultra-rapid lenses satisfactory covering power is limited to the size of the plate for which the lens is listed. Messrs. Taylor, Taylor and Hobson give good advice when they emphasise the advantages of lenses of somewhat smaller working aperture in this respect. The list, which throughout contains very full particulars of every Cooke objective, may be had free on application.

Correspondence.

*** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

** *We do not undertake responsibility for the opinions expressed by our correspondents.*

A CAMERA ATTACHMENT FOR SMALLER DARK-SLIDES.

To the Editors.

Gentlemen,—An arrangement for using ¼-plate slides in a ½-plate camera was recently described by a correspondent. It was made by sawing a square hole for the ¼-plate reversing-frame in a board cut to fit the ½-plate camera.

Having but few tools, I adopted the following method, which may appeal to others. In my case the fitment had to be 1¼ in. wide. A picture-framer made me a plain oak frame, wider than 1¼ in., with the rebate a close fit for the ¼-plate reversing back, the nails at the corners being well sunk with a nail-punch. I then planed down the outside of the frame until it fitted the ½-plate camera. A few simple brass catches completed the work.—Yours faithfully,

OLD HAND.

A NORTHERN FAIR.

To the Editors.

Gentlemen,—It is certainly interesting to read in the "B.J." about the Photographic Fair in London, but I think the promoters or manufacturers should consider it is not the privilege of those up North to attend. If necessary to hold one in London, could not another be arranged, say, here in Manchester or Liverpool, and so give those in this part of the country an opportunity of seeing the latest and best in photography?—Yours faithfully,

FRED DESBORDES.

33, Arrow Street, Broughton, Manchester.
April 17.

HALATION AND DEVELOPMENT.

To the Editors.

Gentlemen,—The correspondence in your columns on this subject is extremely interesting, and we may hope to get some valuable help from the varied experience of the writers. My own opinion, formed from some years' architectural work, is that the freedom from halation depends more on the quality of the plate than upon the developer. A good many years ago I was using a brand of plate that simply refused to give halation, except under the most difficult conditions. I can recall only one subject which showed it badly. This was the interior of a large barn, and the only light came through slits in the wall, some of which faced the camera. In this the halation went deep down into the film; rubbing down was of little use, and a considerable thickness of the film had to be

scraped away to get rid of the halo. In those days I scoffed at plate backing, as with the plate I was using I did not require it; but, alas, each succeeding batch of plates had less and less of the non-halation quality, till at last the backing with brunswick black varnish failed to stop halation. The only fault of the first few batches of the plates was their slowness, but for landscape and exteriors of buildings they were excellent, and for interiors they were not so slow as to cause any great inconvenience. I found they gave excellent copies of black and white drawings, quite as good as the process plate of to-day, but with far shorter exposures than process plates require. I usually developed them with rodinal, which may be described as a "soft" developer, giving a short time of appearance, but rather a prolonged total time to obtain density. But with this particular plate density was obtained so quickly that I used rodinal to avoid excessive contrast. These plates fixed extremely quickly, and dried very rapidly, and had many characteristics of a process plate, but were much more rapid.

The gelatine film carrying the silver bromide was extremely thin, and the question occurs to me, had this anything to do with the absence of halation? There we had a very thin film of gelatine, containing sufficient silver bromide to provide a brilliant image when using a "soft" developer for a short time. Would this not mean that the grains of silver bromide were packed closely together in a very thin film of gelatine? Would not this state of things prevent the scattering of light among the grains of silver bromide? And would not the reverse conditions, fewer grains of the sensitive salt (requiring a 'harder" developer and longer development), scattered about in a far thicker film of gelatine, allow light to spread through the film, till it reached the glass support, to be reflected back again among the scattered grains of silver bromide?

The diversity of view as to whether slow or rapid developer is better is extraordinary, and greater than I remember to have seen on any other subject. This proves the difficulty of the problem to be solved. I am afraid, myself, that development is not the real solution, but it is probably one step forward. I believe the emulsion plays an important part, and also backing. In using panchromatic plates for copying pictures in colour I find that backing is absolutely necessary, but it will not entirely prevent halation in architectural interiors, as I found when taking a number of negatives of buildings lighted by incandescent gaslight, in which several of the lighted burners appeared on the plate. But the solid black backing on panchromatic plates is most useful in minimising halation, the thin red film so often used on ordinary plates has very little effect, I think.

Non-halation plates, having a stained film under the sensitive one are helpful, but I have had some bad cases of halation on them. Double-coated plates are better, even if they take a long time to fix and wash, but even then they take less time and attention than twenty-seven minutes or two hours to develop. Films are supposed to give less halation than glass plates, but I have not found that there is much difference. I should prefer a well-backed plate myself.

In my former letter on this subject I mentioned a bad case of halation I had just had, from a window in a dark church, over a war memorial, where the halation spread half-way down the plate. But during the exposure some sweeping of floors was going on, which, no doubt, increased the halo. The second attempt was far more successful. I covered up the window on the outside that caused the trouble, after a few minutes' exposure, and gave seven hours, instead of two, and also used a larger stop for the rest of the subject. In most cases, of course, the covering of the window causing the trouble is impossible, but there is no doubt, I think, that full exposure and steady development is likely to reduce the chances of halation.—Yours faithfully,

BIFOCAL.

To the Editors.

Gentlemen,—The letter of Mr. Wilson, in the issue for March 14, on the subject of halation, leads me to give the methods which I use for avoiding trouble of this type. These methods are in common use in America, but may or may not be in England, and, at any rate, may be unknown to some.

It is evident from the remarks that Mr. Wilson made that provided the exposure given the plate is not sufficient to allow the light to reach the back of the plate, there will be no trouble from halation. It is also evident that the more development extends into the body of the emulsion the more the reflected light will make itself evident, and the halation will be more in evidence. On the other hand, if we are able to get sufficient density and contrast by developing the image on the surface rather than in the film, that we can, to a large extent, avoid halation. The following methods are all based on this principle of developing the surface rather than the depth of the film.

A common method which is often used and which is effective is that in which the alkali is reduced below the normal amount. If the amount of carbonate in a pyro-soda developer is reduced to ¼ and ½ of the usual amount, development will take place to a greater extent on the surface than if a full strength solution is used which tends to work down into the film. It would also seem that the surface developers, such as metol, eikonogen, rodinal, etc., would have less tendency to halation than developers, which work more in the film, such as strong pyro, hydroquinone, and glycin. In practice I have found this to be the case, and the following formula, which is taken from the Cramer plate manual, has been my mainstay in the treatment of subjects of extreme contrast for some time, and has proved very satisfactory. The formula which works best on plates that are fully or slightly over-exposed is as follows:—

Water	40 gs.
Metol	50 grs.
Hydroquinone	240 grs.
Sulphite	960 grs.

For use take one part of the above to one part of water. Owing to the absence of carbonate, development will be slow, requiring as much as 20 to 30 minutes at a temperature of about 70 degrees. Do not attempt to use this at a lower temperature than 65 degrees F., as development becomes too slow.

Much depends on the use of the proper plate. Here we favour a double-coated plate to eliminate halation, which it accomplishes by increasing the thickness of the emulsion, and its efficiency is high. Backed plates are more often used in England, I understand; but there are extreme cases in which the contrasts are beyond the range of either the double-coated or the backed plate, and it is in these cases that the formula I have given above will be of value.

Apologising for the length of this letter, which, I hope, will be of benefit to the profession.—I am, yours very truly,

CARROL B. NEBLETTE,
Head Division of Photography,
Pennsylvania State College, PA.

To the Editors.

Gentlemen,—I have not until now had an opportunity of seeing the last few numbers of your Journal, but I note a letter by Mr. Godfrey Wilson on the above subject in your issue of March 11, to which no reply appears to have been given so far. May I state the case as I think it should be given?

The difficulty arises from the fact that development as a factor in the case has not been given due prominence. Figs 1 and 2 (March 11, p. 147) are substantially correct diagrams, assuming that No. 1 represents the position of the developed grains, with normally correct exposure and development, but it is not correct as a record of the locus of the light-action in exposure. The ray of light must have penetrated the film entirely, and was reflected from the back internal surface of the glass, causing true halation.

In those places in the film where the light-action has been strong, normal development is not sufficient to develop the silver grain in the lower strata owing to the fact that the developer diffuses slowly, and in its passage becomes exhausted. Abnormally long development would accomplish this.

In those parts of the film where little or no light-action has taken place the developer can penetrate right through the film with undiminished strength in a normal time of development, and can blacken the silver grains in the lower layers of the film which have been acted upon by the light reflected from the glass. The result is true halation. Any method of development which limits the action of the developer to the upper strata of the film will lessen or prevent true halation, but it will not cure irradiation, which is due to light reflected from particle to particle in the film.

HAROLD HOLCROFT, M.A., F.R.P.S.

Gatcombe, Tettenhall, Staffs.

To the Editors.

Gentlemen,—I am following with considerable interest the correspondence regarding "Halation" in the columns of the "British Journal." As a commercial photographer I am frequently called upon to deal with the difficulties of front lighting, such as photographing objects in front of a window light, the light from an open door, or against the north light window system of factories, etc.

My experience certainly leads me to use the weak solution for developing, and not a concentrated solution. Working usually in size 12 in. × 10 in., I use flat films, give ample exposure, and develop with maker's formula for pyro soda developer, but diluted with at least an equal bulk of water. If necessary, ferricyanide reducer is used locally to clear any portions that may have a tendency to extra density. Printing on soft bromide paper still further reduces any possible harshness, and the result is a print full of detail and without halation.—Yours faithfully,

KENDRICK G. SMITH.

21, Howard St., Loughborough, April 16.

STEREOSCOPIC RELIEF.

To the Editors.

Gentlemen,—Will you allow me space to thank those who have so kindly written to elucidate the points raised in my letter on this subject? I have been very flattered by these expert responses, and have never felt so well informed as I am at present.—Yours truly,

F. C. TILNEY.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

R. C.—Collodion prints require to be glazed by means of enamel collodion, as described on p. 457 of the current "Almanac."

W. B.—So far as we know there is no solution which will change the colour of a sulphide-toned print to a darker shade to any material extent.

F. W.—You should simply apply to the Secretary of the Royal Photographic Society, 35, Russell Square, London, W.C.1, asking for a form of application for membership. If you do not know a member of the Society to act as proposer, we are quite sure that the Secretary would find one for you.

W. P.—We are afraid it is not possible to draw up a list of innocuous chemicals, because things that are harmless to one person are found to affect others acutely, and vice-versa. Generally speaking, so far as developers are concerned, pyro is the least liable to affect the skin. We never heard of skin trouble from developing until the newer developers came out. As regards prints, probably amidol would be without effect upon you, although it affects some people. If you cannot use it, then the best alternative is to use ordinary hydroquinone developer.

L. E.—The dyes which are commonly available have changed so greatly owing to commercial conditions created by the war, that we are afraid most of the current text-books are of very little use except to a chemist familiar with the constitution of the dyes. There are, however, a great many books on dyes, but most of them in German or French. We think your best course would be to go and have a look at all of them in the Library of the Patent Office, 25, Southampton Buildings, W.C., which is open free until 9 o'clock every night, and where the assistants will render every service to a visitor anxious to discover books on a particular subject.

A. W.—(1) A reflex camera can be used on a tripod, but it is very awkward for use in this way owing to the focussing screen being on the horizontal top of the camera. (2) We have published various articles on quantity developing of roll-film, and Messrs. Houghtons issue a very excellent catalogue (Trade Developing), which contains not only full particulars of equipment, but formulæ for developers, fixers, etc. (3) It is rather too much to say that an R.R. lens used on a plate half the size of that for which it is tested will not show astigmatism. Although astigmatism is a property of oblique rays, and therefore is shown in the margin, in the case of the rectilinear it is liable to become evident at a smaller obliquity than is determined by using a whole-plate lens on a half-plate.

T. B.—(1) When using soft focus lenses of the Aldis, Dallmeyer and Cooke types the diffusion must be adjusted before focussing. It is also advisable to set the iris to the aperture it is intended to use at the same time. (2) As a rule, printing-out papers will not keep in good condition for more than a few months. Even if they do not discolour, stale papers will not give satisfactory tones. Bromide papers, if stored carefully, will keep in good condition for a couple of years or more. Some brands keep better than others. Plates vary greatly in their keeping qualities. We have to-day made a good negative on an ordinary plate made in 1908. Very rapid plates are not reliable after a year or so. (3) The choice of a background is entirely a matter of taste, at present very dark backgrounds are popular for bust pictures, but in our opinion a graduated ground is preferable. For full lengths rather dark drapery or a vague cloud effect is generally used.

H. E.—The great diameter and very great focal length of the condenser certainly accounts in part for your long exposures. The condenser should bring the light to a focus in the diaphragm of the lens, but, of course, if you are using a 7-in. lens with a 12-in. condenser the lens has got to be much too near to the condenser, so that the diaphragm, instead of being at the apex of the cone of the rays, is somewhere midway along towards the base of the cone and, therefore, receives only a fraction of the light. There is no ready method of calculating diameter of condenser suitable to focal length of projection lens, but a useful average is a 9-in. lens for an 8½-in. condenser. Of course, the use of ground glass upsets, in a measure, the cone formation of the light from the condenser, but not sufficiently to prevent your deriving a good deal of advantage from having an objective of focal length appropriate to the condenser. Nevertheless, we should have thought that with bromide papers your exposure would be a good deal shorter than four minutes. Perhaps you are using a somewhat slower paper, but that you do not say.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3182. Vol. LXVIII. FRIDAY, APRIL 29, 1921. Price Fourpence.

Contents.

SUMMARY.

A series of reports of last week's Congress of the Professional Photographers' Association occupies the bulk of this issue. It covers the whole proceedings, with the exception of the annual general meeting, the report of which is held over until next week. The reproduction of the group of Congress members with a key to their names will be found on the advertisement pages, Supplement 6 and 7.

Madame Yevonde, in a paper on photographic portraiture from a woman's point of view, emphasised feminine intuition as one of the mental qualities which put the woman photographer at an advantage in comparison with the mere man. She urged women photographers to come together within the membership of the Association, and discoursed on the present position of women as responsible heads of studios in an address which contained some witty sallies. (P. 251.)

Mr. S. H. Greenway, of Northampton, read a paper on canvassing frauds. He described methods which had been successful in combating them, and urged that anti-canvassing literature, in the shape of window bills, etc., should be officially prepared and issued by the Association. (P. 248.)

Following a paper on insurance, discussion ranged round the extra liability incurred by stock of celluloid in any quantity. The consensus of opinion was that the insurance company should be notified of the existence of any floating supply of celluloid, large or small. (P. 247.)

In a lecture on architectural and technical photography, Mr. H. W. Bennett defended the wide-angle lens for the more effective photography of many outdoor subjects, and illustrated the very great pains which it was necessary to take in dealing with difficult subjects. (P. 250.)

Mr. J. H. Pledge, for the Kodak Company, lectured on dark-room illumination, and emphasised the advantages of green safe-lights and semi-transparence (diffusion) of any safelight. He also referred to the economy of indirect lighting of the dark-room by means of an inverted lamp near to the ceiling as a supplement to the ordinary lighting over the work bench. (P. 249.)

Mr. N. E. Luboshez held forth *more suo* on lighting in portraiture. (P. 254.)

Mr. C. P. Crowther lectured on psychology in the studio, and drew from Mr. Marcus Adams a confession of his sub-conscious influence over children. (P. 255.)

Notes on the annual dinner and the excursion to the Kodak Company's works at Harrow will be found on page 256.

A portrait of the new president of the P.P.A., and some notes on his personality and business will be found on page 258.

The programme of the Congress of the Photographic Dealers' Association was unhappily dislocated by the threatened railway strike, but part of it was carried out. (P. 257.)

At the Croydon Camera Club last week Mr. Vivian Jobling had many practical things to say on the mounting of prints, and gave a formula for making dry-mounting tissue. (P. 256.)

The value of a list of lenses giving the makers' numbers in the event of a lens being stolen is the subject of a paragraph on page 245.

EX CATHEDRA.

Soft-Focus Lenses. When using soft-focus lenses in which the diffusion is produced by introducing more or less spherical aberration it is very necessary that the lens should be adjusted with regard to both diffusion and aperture before proceeding to focus, otherwise the resulting negatives are likely to be disappointing. It is well known to all who have studied the subject that when spherical aberration is introduced the focal length of the lens is altered to a slight extent, so that if a certain point in the subject is sharply focussed, and the adjustment then made, a point in another plane comes into as sharp focus as the adjustment will allow. This often quite spoils the effect of the picture. Again, when spherical aberration is present, an alteration in the working aperture causes an alteration in the focal length, again shifting the point of sharpest definition, so that if the precaution we have mentioned is neglected the result is bound to be unsatisfactory. The lens makers generally point this out in their circulars, but, unfortunately, soft-focus lenses are usually handled by artistic folk who do not read instructions. If in addition to spherical, chromatic aberration is present, tests should be made to ascertain what allowance is necessary to get the best average of definition.

* * *

A Wise Precaution. Every photographer knows that all lenses of any value and many cameras are engraved with a serial number by their makers, but probably not one lens owner in fifty keeps a record of such numbers. This means of identification is valuable in the event of a lens being lost or stolen. It is not perhaps generally known that a list of articles which have been reported to the police as stolen is issued at intervals to pawnbrokers and secondhand dealers, and in the case of lenses the number is the only means of distinguishing one from another. We have heard of an ingenious method by which a photographer recovered a stolen lens, which may serve as a hint to others. He immediately advertised under an assumed name for a similar lens and received an offer of one from a dealer. This proved to be his own, and from the description of the person who had sold it he was able to identify the thief. A notification by advertisement or postcard addressed to those who deal in apparatus would often lead to the recovery of the lens, if it did not to the punishment of the offender. A well-known dealer told us that, having an expensive hand camera offered for a mere trifle, he made some pertinent inquiries of the would-be seller, who offered to leave the instrument for inspection but never returned. A little later the owner was discovered. It is scarcely necessary further to point out that a detailed inventory of items of equipment is invaluable in the event of damage to a photographer's premises by fire. Its preparation is, in fact, an ordinary business precaution.

Finishing Prints. Although the practice of using the knife has become universal in negative retouching, comparatively few photographers use this or other method of removing part of the image, such as abrasion, upon their prints. Now that matt surfaces are almost universally used for portrait work this method may often be usefully employed upon contact prints as well as enlargements, with much better effect than can be obtained by using body-colour. As in retouching, the knife must have an extremely fine edge and the gelatine surface must be bone dry. Fine pumice powder applied with a rubber stump is also useful for lightening such portions as need it, either on bromides or carbons, especially for removing any "tint" from the margins of vignettes or the high-lights of the subject. In careful hands a hard typewriter eraser may be used to good purpose. The glass brush erasers are also useful tools, but we have found that the fine particles of spun glass, which break off while working, are apt to find their way into the softer parts of the hands and cause considerable inconvenience.

USING YOUR EYES.

HABIT is a very valuable part of our mental make up; it enables work of any kind to be repeated with the minimum of effort, and makes constant reference to memory unnecessary. But it is not an unmixed blessing. For instance, when one has walked into the same studio day after day for ten years or so, it becomes very difficult to see the place as others, less well acquainted with it, see it. For one fails to notice the "effect" of a studio or reception room when it becomes too well-known. This inability really to "see" their own business premises is a failing, by no means confined to the photographic profession, as visits to many retail shops will show; but it is probably more important in the case of a studio than in any other. There is no easy standard of comparison in the studio business, and you are not likely to attract customers, however good your work, unless your premises are attractive.

To begin with, if your window or show-case does not carry a good effect, you will not get many customers inside at all. If you get them inside and your reception room is unattractive, the chances are, they will not order. And if dressing rooms and studio are not "nice" you will not get many clients returning for more. It would be altogether useless to advise the average studio proprietor to spend some hundreds of pounds on redecoration; that is too drastic, anyhow; it is the way in which things are arranged rather than their quality that makes for "effect." In fact, it is far more likely a business will benefit by the removal of some of its present furniture and odd accessories than by bringing in more. The great thing is to see a place of business as if through the eyes of a customer entering for the first time. This is not so easy as it sounds, and it may be that a few notes on some of the more vital points will be of assistance. They are the outcome of visits to some hundreds of studios, ranging from the humble sticky-back den to the "five guinea a dozen" type of business.

It is very surprising to note in what a large number of businesses the spotting and finishing of prints is still carried out in the reception room. This is bad from at least two points of view; a number of odd prints waiting to be finished or to be packed do not add to the appearance of a room; however carefully they are stacked they will give an untidy impression; and, in the second place, many sitters dislike the idea of their photographs being exposed to the public, especially in a half-finished state, in deshabille, as one might say. Then again, negatives should never be brought into a reception room; they often are, either for sorting or for some other reason. It is a mistake, not because it gives away "trade secrets," but because any evidence of work, except the finished product, looks untidy and slovenly to an outside eye. The vast majority of reception rooms are over-crowded. Let the specimens from which customers will choose be kept in a portfolio or cabinet; a few really good pictures may be displayed in frames, but let them be only a few. Nothing looks less artistic than a heterogeneous collection of prints covering every available inch of wall and table space. It is difficult to stop them accumulating; in fact, the only permanently satisfactory way is to make a rule that for every new print shown an old one must be withdrawn.

With regard to the general arrangement of the reception room, there are two main points. It should be as unlike a retail shop as possible; a few comfortable chairs for the use of customers when waiting are, of course, necessary, but a lot of small chairs stuck all over the room do not look well and are not nearly so restful for sitters as are one or two comfortable armchairs or a settee. If a dealer's business is run in connection with a studio, the two branches should be kept as separate as possible; the shop and the reception room should, whenever possible, be quite distinct. The aim should be to impress the customer that you are not selling photographs as an ironmonger sells tin-tacks, but that you are an artist, taking every case separately and giving it individual attention.

The dressing-room is an apartment not usually so open to criticism as is the reception room, but in many cases it leaves something to be desired in the matter of "freshness." If a brush and comb are provided, as they should be, they must be kept scrupulously clean; cigarette ends or stray strands of ladies' hair must not remain about; and the window must be clean and the room well dusted. All very obvious, of course, but liable to be overlooked in a busy studio.

The arrangement of a studio depends so much on the work done in it, that any drastic alteration is inadvisable unless it is obviously necessary; but there are a number of things of minor importance in themselves which add up to quite a respectable total in the general effect. If newspapers or magazines are provided for the amusement of customers, see that they are kept up-to-date, and are removed before they get to the dog's ear stage; if some of the blinds are out of use, do not neglect them, keep them free from dust and cobwebs and neatly folded or spread as the case may be. A fault, both from the point of view of appearance and of work, is too much furniture. That old accessory and those old backgrounds that you don't use now, but keep in case you may need them—you never will—get rid of them, sell them or use them for firewood; anything to get them out of the way. They collect dust, and however carefully they are stored, look untidy, and, of course, they fill up much space which would be far more useful as extra working room.

To turn from consideration of those parts of premises likely to be seen by customers, while thinking of re-arrangement, it is just as well to see if the workroom accommodation is being used to the fullest advantage. Here, utility will be more studied than appearance, but the same remarks hold good to a great extent, the less disused out-of-date apparatus there to collect dust the better. Plenty of light and fresh air should be available in every room. One often takes the term "dark room" too literally. The more light you can get in it, of the right sort, the better; better for your eyes, better for your work, and better for your breakage bill for dishes

and measures. It is strange what a number of good workers still use "ruby glass" as their dark-room light-filter. One can have twice the light with far less risk by using a scientifically constructed gelatine-film safe-light.

If there is a number of workrooms the work should go from room to room with as short journeys as possible; for instance, the mounting room should, when possible, be next door to the spotting room, and yet one often finds them at opposite ends of a building. It may seem a small matter, but the time wasted in the course of a year in long journeys from room to room must be considerable.

Up-to-date apparatus is the best investment it is possible to make. Labour-saving means money saving in the long run, even if it is a one-man business. Every professional should make a practice of seeing the latest in apparatus at least once a year. There are many high-class firms doing a good business and using apparatus that should have been on the scrap heap years ago; this means waste of labour in any case, and usually it prevents a higher standard of work being attained. It is not so much in the way of cameras and lenses that firms are behind the times, but in the less-considered items—trimming boards, mounting machines, printing boxes, drying cupboards and dozens of other things.

THE P.P.A. CONGRESS.

Mr. Alfred Ellis took the chair on Tuesday afternoon, when the first item on the programme was a demonstration by Mr. A. C. Braham (of the Autotype Company) of the "Carbro" Process. He said that the modifications of formulæ and methods in working the process were due to Mr. F. Garon, of Southend, an amateur, who had devoted ten or eleven years to the study of the subject. Mr. Braham carried the process through in every detail, and his manipulations were followed with keen interest by the large company present, who afterwards accorded him a hearty vote of thanks.

A paper was next to have been given by Mr. A. C. Watts, of Catford, on "Salesmanship in Photographic Business," but the Chairman said that, unfortunately, Mr. Watts's services had been called upon by the Government in connection with the existing industrial situation. It was the only item which had had to be withdrawn from their programme.

PHOTOGRAPHERS' INSURANCE.

Mr. Dunford, representing the Eagle, Star, and British Dominions Insurance Company, read a paper on "Reasons why you should insure through the medium of the P.P.A."

An interesting discussion followed.

Mr. Sarony (Liverpool) raised an important question. Now that films were so popular, what was the position with regard to insurance against fire? Many photographers now stored flat celluloid films.

Mr. Dunford said that he took it this was a recent addition to the photographers' stock, and it would come under the ordinary fire hazard. There was generally a survey in that connection.

Mr. Lang Sims pointed out that instead of using glass many photographers now used films, and probably this would increase the fire premium. It was a point which should be discussed.

A member said that he had raised the question with one company, who had replied that there would be no increase in premium, but that they would carry the risk involved in the change. The company in question was the Fine Art Company.

Mr. Dunford said that the matter could not be decided until a survey had been made. Quite likely the rate might not be increased above the normal. It would depend on the circumstances in each individual case.

Mr. Swan Watson asked whether, when photographers ceased to use glass and took up the use of films, it was necessary to acquaint the insurance company with the fact?

Mr. Dunford replied that certainly he would say that that course was incumbent upon them.

Mr. Swan Watson further asked whether, in the event of a fire, the fact of the change from glass plates to films not having been indicated, the claim could be sustained?

Mr. Dunford replied that if any photographer kept a large quantity of films on his premises, and had no such films when his policy was taken out, he should certainly advise the company.

Mr. Swan Watson said that there might be as much danger in one as in a lot.

Mr. Dunford advised that the photographer should be on the safe side, and tell the company he had so much film on his premises; then a survey could be made if necessary, and it could be ascertained by the company in what condition as to security the films were kept.

Other members remarked that they understood from their insurance company that if the films were safely stored the policy covered the risk.

Mr. Dunford said that he had been twelve years in the insurance world, and he could not think that any company charged the same rate for celluloid as for glass.

A member asked where was the dividing line with regard to the quantity of films stored?

Mr. Dunford said that if they had any quantity it would be best to advise the company.

Mr. Lang Sims thought it would be better if all policies now covered a certain amount of celluloid. The company might arrange premiums according to the amount of celluloid on the premises. A photographer might have a little celluloid in hand one day, and it might be gone the next day or the next week. It would be very hard if such a man had his place burned down and his claim was not met. Far better to have all policies cover a certain amount.

Mr. Dunford said that he quite agreed that some such arrangement as Mr Lang Sims suggested might be made. The matter would receive the attention of his company.

A member said that without some such provision a policy would not be worth the paper it was written on.

Mr Sarony remarked that he did not think they gave sufficient thought to the inflammable nature of celluloid. After 26 years in the cinematograph world, he knew the danger, and he hoped the members of the Association right through the country would make every effort to see that their policy covered this risk, no matter how small the quantity of film might be.

The Chairman said that it was obvious that if a new risk, not previously covered, was introduced, and the company was not notified, the policy might be rendered invalid. He felt sure that the matter having been discussed, Mr. Dunford would go back and consult with his company.

Mr. Dunford agreed to do this.

Mr. Swan Watson asked if there was any policy covering the theft of a lens by a person who came into a studio in a crowd. Was that in the "all-in" policy?

Mr. Dunford: If you take his photograph and he takes your lens—(laughter)—it is covered by the burglary, housebreaking, and larceny policy.

Mr. Dunford was warmly thanked for his paper.

CANVASSING FRAUDS.

Mr. S. H. Greenway (Northampton) read the following paper on "Canvassing frauds, and how to deal with them."

There is probably nothing easier with which to defraud the public, or that section of them which is easily bamboozled, than the photographic enlargement bait.

Since the war, I am told on the authority of the police, the country swarms with canvassers of this kind, whose stock-in-trade is generally two or three passably good bromide specimens, a plausible tongue, and promises of a really high-class enlarged photograph from any original entrusted to them.

I have been on the scent of a worthy couple operating in small towns near Northampton, but not in the county, and victimising some of my own customers.

The *modus operandi* of these slippery humbugs can be taken as typical of many others, who work in pairs, generally of opposite sexes, but not always husband and wife, although nominally so, for the sake of appearances.

In the cases which I have personally investigated, the lady appeared first on the scene, invariably when the man of the house was absent from home, on the plausible plea of providing a fine picture of some dear one, lost in the war, or other relative or friend. The wife or daughter of the house would part with a P.C., or snapshot, and generally a small deposit towards the cost, which I found varied according to the circumstances of the occasion.

This lady canvasser, I use the term "lady" advisedly, was a very loquacious and persistent woman, and the simple country folk she tackled hadn't a ghost of a chance. They were simply talked into parting with, in some cases, a cherished photograph and money before they knew where they were. The canvasser had one or two decoy local specimens supplied free, or fairly cheap (as a guarantee of good faith), and, needless to say, these were *faked* up for the occasion and provided excellent bait.

Within a few days the other partner made his appearance with what he called the proof; merely a bit of bluff to get a further instalment towards the 17s. 6d. charged.

Some held on to this crude and unfinished effect for which 7s. 6d. was demanded, rather than risk further outlay in finishing up a dubious result. I was shown two or three of these precious specimens, cheap and nasty bromides, coarse and over-printed monstrosities about 24 by 19, rough mounted, and already warped into a cylinder shape.

In cases where the victim refused to pay a further instalment the proof was retained by the firm, and nothing further was heard of the deposit or the original. One young man I interviewed, an ex-service fellow, had parted with a brother's photograph and 17s. 6d., the full price charged, and all he held was a worthless receipt minus date or signature.

Eve, in the person of the lady canvasser, tempted him, and he fell a victim to her wiles. I made a test case, and interviewed the Superintendent of the County Police, who explained the difficulties of bringing this class of shady customer to book.

Difficulty 1.—To get any of the victims to prosecute; dislike to advertise the fact they have been sold.

Difficulty 2.—The very thin line between a civil action of process by County Court for breach of contract, as against a proven fraud, *i.e.*, obtaining money and goods by false pretences.

Difficulty 3.—That in most cases the transaction is oral instead of written and signed.

So much for the evil. Now what are the remedies?

This kind of low down business, especially when it exists on a fairly large scale, is about 75 per cent. suspect, as against 25 per cent. genuine and legitimate dealing (I quote official estimates), and injures the whole status of photography as a business. Let a *bona fide* firm send representatives in the wake of these swindlers and see the reception they would get.

Some years ago, when we had a local branch of the P.P.A., we scotched the operations of an outside firm who were canvassing the town under the high-sounding title of some art association. We did that by means of advertising in the local press, and cards displayed in our windows warning the public against parting with photographs or money.

That was the time when the free enlargement stunt, with the compulsory purchase of a cheap German gilt frame, charged at four times its value, was being worked for all its worth.

However, publicity and advice to some of the victims had the desired effect, and the exploiters of trust and credulity cleared out to fresh fields and pastures now.

It is on these lines that the P.P.A. can be of practical service. Any warning notice with the title "P.P.A. of Great Britain" appended would carry far more weight than a local name, and my suggestion is that the Association be asked to supply suitably worded cards for window or showcase display at a small cost, so that the members and the public can be protected when these doubtful agents appear in one's locality.

All genuine firms would hail such procedure with satisfaction.

Some years ago the cynical old sage of Chelsea wrote: "There are 35 millions in Great Britain, mostly fools." I do not know if that proportion still holds good, but it is certainly difficult to understand the mentality of some people we have to deal with.

I put it to these people who were regretting their stupidity and the loss of their money, which, in most cases, they could ill afford—why, with old-established and accredited photographers in their own neighbourhood they entrusted photographs they valued to outsiders and complete strangers without ascertaining their *bona fides*, or even seeing that a proper signature and date was appended to the receipts they held.

You will say this is an exceptional case, and that the natives in this particular place, which, by the way, is *not* Northampton, are pathetically simple. In any case, I did good work in my inquiries, for these specious frauds made a sudden exit, and the likelihood of any return for the sums entrusted to them is very remote.

The annoying part is, however, that all the money they garnered is lost to the legitimate traders, and that so much public confidence is alienated, and photographers as a class are suspect to such people for a long time afterwards.

My advice is: "Do not lightly disregard this spurious kind of competition. Genuine agencies, even if they thrive upon cut prices and slim methods, we have to face; but it is our duty to investigate when doubtful and dishonest means are used, and productions labelled "high class enlargements" are foisted upon the public at ten times their value. Then it is time to act in a corporate capacity for our mutual interests and scotch the game.

Even if our own particular business is not directly affected, we have a duty as members of the P.P.A. to those of our fellow craftsmen to whom this kind of competition is hurtful and exasperating.

S. H. Greenway.

In the course of discussion,

Mr. Lang Sims pointed out that this was no new matter to the Council. Only a short time ago a new member wrote complaining of a similar fraud in his town. The Council replied to the member to the effect that he should put a notice in his window that he had nothing whatever to do with the fradulent canvassers, and that if customers came to him they would be promptly and satisfactorily dealt with. Of course, the great difficulty was to get anyone to prosecute. The Council would welcome any suggestions.

The President (Mr. Frank Brown) said that the police were powerless to act unless private individuals were willing to

prosecute. There had been a similar trouble with regard to painting miniatures, and he had the satisfaction of saving two of his customers £50 by putting them into a position to claim the return of the money they had paid. The only way, it seemed to him, was an extensive issue of warning notices to be placed in photographers' windows. Of course, it was not only a matter of cheap and inferior portraiture, a similar fraud was practised in connection with better work. He had every reason to believe that the Council would be able to stop it in time.

Mr. W. Illingworth (Northampton) said that this was one of the reasons why he had so strongly urged the incorporation of the Association. When they became a registered body they ought to be able to check all this kind of thing much more effectively than at present.

Mr. Greenway, who was accorded a hearty vote of thanks, said, in reply, that he was sure that if the Association issued display notices for the districts affected, for which members would be willing to pay, it would have a pronounced effect in putting a stop to the practices complained of.

DARK-ROOM ILLUMINATION.

Mr. J. H. Pledge, of the Kodak Company, read the following paper on "Dark-room Illumination."

I want to assume that a talk on the subject of dark-room illumination may be of some help to those workers who have not yet had time or opportunity to look closely into this matter. So if to some of you what I have to say may be rather elementary, yet to others I hope there will be some little gain.

For comfortable working in the dark-room we need as much light as is consistent with safety. That is to say, we want to be able to see as well as possible without incurring the risk of fogging the plate or other photo-material we are handling.

The colour and amount of the illumination that it is possible to use therefore depend on two things:—

(1) The sensitiveness of the plate. (2) the sensitiveness of the eye. Both of these factors vary—the eye with the individual, and the plate according to its kind.

It is customary to consider white light as consisting of a mixture of all colours, and if, in fact, we analyse white light with the instrument called the spectroscope, we obtain a band of colour varying from violet through blue, green, or orange to red and deep red—the well-known continuous spectrum.

Without going deeply into the matter, it may be said that, given the same quantity in fair amount of blue, green, red, and violet, to the eye the green and red might look equally bright, but the blue would be darker, and if we wanted the blue to look as bright we should have to take more of it, because the eye is less sensitive to blue than to green and red. But if we reduced very much the quantity of light the result would not be the same. As the quantity of light was reduced the green would appear to lose less than the red, and, finally, when the red had quite disappeared, we should still be able to perceive a faint effect in the middle of the green. This matter has an important bearing on the design of safelights for use with panchromatic plates, about which I want to say a few words presently.

Now, with respect to the sensitiveness of the plate. To daylight, ALL plates have a maximum sensitiveness in the violet blue. This is entirely true of ordinary plates. Orthochromatic plates have an additional sensitiveness in the green, and panchromatic plates are sensitive to the green and red besides the blue, but all are most sensitive to blue. Now although it is quite true to say that an ordinary plate has its maximum of sensitiveness in the blue, it is not entirely insensitive to the other colours, but with sufficient exposure will be fogged by green light and with still more exposure by red light. It is therefore obvious that for dark-room illumination we cannot use blue light. It is, however, possible to use a green light or a red light, or a mixture of green and red, that is, yellow, though it would have to be a very deep yellow, and this could only be used for slow plates and papers. Therefore for the handling of photographic material of ordinary sensitiveness an orange or red light is usually best.

Regarding the standardisation of the various glasses now usually known as safelights (so called, I suppose, because they are not lights, neither are they entirely safe), prior to 1907, when Dr. Mees, of Wratten and Wainwright, made an investigation of the subject. There were no standards, and the photographer bought canary or ruby fabric or glass, and was satisfied so long as he got no fog on his plates. When he did get fog he usually proceeded to decrease the amount of light coming from his dark-room lamp, perhaps by fastening another piece of fabric round it. He did not know whether he was getting as much light as it was possible to have with safety, and, as a matter of fact, Dr. Mees found that, in general, dark-room lights were much darker than they need have been.

The standard of safety adopted by Dr. Mees was that a plate might be exposed for half a minute at 3 ft. from the dark-room lamp without showing a trace of fog, the intensity of illumination being 8 c.p. directly behind the safelight, or 16 c.p. if the light were reflected through the safelight. Of course, development always takes more than ½ min., but it is never necessary to expose the plate directly to the light for a longer total time than ½ min. The developing dish should be covered for the greater part of the time of development, or at least kept in the shade, and the direct light of the lamp not allowed to fall upon the plate. With the growing popularity of tank and stand development these remarks, which apply primarily to dish development, will not be so generally applicable. There is another point which has been frequently overlooked in the design of dark-room lamps. In a dark-room it is necessary to see not only the plate that is being developed, but also the position of the tap, measures, and so on. Now a diffused light is much better for this purpose than a direct light, and a great deal more of the surroundings can then be seen with the same intensity of light falling on the plate, and strain on the eyes is thereby minimised. In point of fact, the safelight itself, 10 by 8 or so in size, should act as the light-source, and must therefore be translucent and not transparent. A ruby or other glass through which one can see the source of light is, of course, transparent, but a safelight, such as those of the Wratten series, which one cannot see through owing to the diffusing medium, is called translucent. The Wratten safelights are all composed of two sheets of glass coated with dyed gelatine. Between these two glasses is placed a diffusing medium, usually paper, and sometimes this is dyed as well. Here a word of caution. A dyed gelatine safelight is preferable to either glass or fabric, because it enables exactly the right colour to be used and of just the right strength. But it is necessary that the lamp should be thoroughly well ventilated, otherwise the coating may be damaged by the heat. Every Wratten safelight box bears this caution, but I am afraid it is not always observed.

The special Wratten dark-room lamps are so designed that a current of cool air is constantly passing over the surface of the safelight all the time the lamp is in use. This applies to all sizes and forms of the Wratten dark-room lamps, and it is impossible in a Wratten lamp to spoil a safelight through overheating, however long a lamp may be running. At our Harrow works we have some safelights in use in lamps lighting dark corridors or exits which are continually alight, and we have not yet had a failure of a safelight through overheating. Their end, when it does occur, is usually a violent one, perhaps by being dropped while cleaning, and even a Wratten safelight will not stand that kind of treatment often.

As the sensitiveness of different photographic materials handled in a dark-room may vary very much, it is obviously desirable, on the ground of comfort and convenience, to be able to control the colour and amount of light in use. For fast ordinary plates we need a deep red light, for slow lantern plates a bright yellow one, and so on. We now list a series of nine varieties of Wratten safelight, covering the whole range of light-sensitive photographic material now available, from the slowest plates and papers to the fastest portrait and most sensitive and rapid panchromatic plates on the market. These

safelights have all been designed with the same margin of safety, and their standard is very rigorously kept up. Generally speaking, we do not recommend daylight as the light-source for dark-room illumination, as it varies so much in intensity, and any given safelight may be unduly dark at one time and far from safe at another. A fairly constant artificial light-source is much better.

We are frequently asked why green is the colour of the safelight recommended for use with panchromatic plates. It is not, of course, that panchromatic plates are insensitive to green, but is due to the fact to which I referred just now, that the average eye is more sensitive to very weak green light than to a similar amount of any other colour. A panchromatic plate is easily fogged by exposure to green light, but given a very weak green and a very weak red light, both of equal visual intensity, the red light would cause fog trouble in a much shorter time than the green. Hence the most useful and safest safelight for panchromatic plates is a dull green light.

During the last few years a form of supplementary lighting of dark rooms has come into use—the indirect lighting system. This usually takes the form of an electric lamp suspended from a whitened ceiling and projecting its light upwards only. It is reflected practically all over the dark-room from the area immediately above the lamp and renders the use of the dark-room very much more easy, most especially when more than one person is using the same room. This method is in practically universal use at our Harrow works, in the coating and packing, developing and printing rooms, and elsewhere. The method is now largely in use in most photographic works and in many professional dark-rooms also. The safelights we recommend for use in such lamps are those in the list now on the screen. To those seeing this method of lighting for the first time the amount of light permissible with safety will probably be a surprise. We do not recommend this as taking the place of the lamp over the work bench or sink, but as an accessory or additional method.

To summarise, for dark-room illumination—

Do not use canary or ruby fabric or glass of an unknown factor of safety.

Use a screen which is translucent and not transparent.

Use a screen which permits the greatest amount of light possible with the particular photographic material in use. From this it follows that more than one screen should be available if plates or papers of widely differing speed or sensitiveness are employed in the same dark-room.

See that your dark-room lamp is properly ventilated so that the safelight does not become unduly heated.

If more than one person is using a dark-room at the same time consider the installation of a Wratten ceiling reflector lamp as an efficient aid which will soon save its cost in reducing breakage of measures and dishes and in preventing collisions between workers who would, of course, usually have a valuable negative in their hands at the time.

J. H. Pledge.

ARCHITECTURAL AND TECHNICAL PHOTOGRAPHY.

Under the presidency of Mr. Frank Brown, a lecture was given on "Architectural and Technical Photography," by Mr. H. W. Bennett, F.R.P.S.

Mr. Bennett said that there was always a large amount of good technical work to be done—architectural, engineering, scientific, including copying. One essential to begin with was that the man who was required to do technical work must have a certain understanding, not merely of his photographic technique, but of the technical qualities of his subject. It was hopeless to expect good animal photographs, for instance, from a man who was not fond of animals, or good photographs showing machinery from one who had no understanding of the purpose and functioning of the machinery. Some years ago a large French engineering firm installed a new system of signalling at a station on the line from Paris to Madrid. A photographer was asked to take about two dozen photographs, and this he did in one day, but, however good they might have been as photographs, when the manager saw them he threw them aside. Then he (the lecturer) was called upon to undertake a series of negatives, and this he did in three days, and from his twenty-four negatives some 700 or 750 prints were ordered, therefore they met the case. In photographing machinery it was essential to understand the working of the machinery. Such a position for the camera must be taken as would show the working parts of the machine.

Mr. Bennett showed one or two pieces of home-made apparatus—one of them an arrangement for preventing the tripod slipping on a slippery floor. It consisted simply of three laths joined together in such a way that they could be extended flat and tripod-fashion on the ground; and having holes to receive the points of the tripod, it effectually prevented a tripod slipping on, say, a glass surface, or making holes in a rich carpet.

For all technical work one must necessarily have a camera with a large range of rising front. At times it was necessary to lift the lens very high in relation to the centre of the plate; this he succeeded in doing in the case of his own camera by means of a panel arrangement on the camera front. With regard to lenses, as an architectural photographer he wanted to defend the wide-angle lens. He had heard many photographers in the past speak strongly against it,, but he regarded it as not only a necessity at certain times, but as an advantage at many other times. There were occasions when he had the opportunity of using either a long focus, a medium focus, or a wide angle, and he chose the wide angle because it gave him the most natural and pleasing result. He would never advocate an excessively wide angle—that is, an excessively short focus—in relation to the plate. As a general rule he preferred to use a lens not shorter than five-sixths of the length of the plate with which he was working. Such a proportion of focus to plate would give, measured on the diagonal of the plate, a capacity of just over 70 deg. Most of his whole-plate work had been done with a lens of just under 7 in. focus; most of his 12 x 10 work with one of 10½ in. focus. His objection to telephotographic work was that the perspective was so slight that in many cases the impression was almost that of a photograph of a model. But if a fairly wide-angle lens were used one got the effect, in the case of a tall building, of looking upward. A photograph of a high building, taken with a lens of moderately short focus relative to the plate, gave in the resulting print this looking-upward impression to a remarkable degree. This was provided, of course, that the photograph was taken from the ground, and he always felt that in architectural work photographs should be taken from the ground, such being the natural and intended point of view. There was just one reservation. When taking very small subjects with a wide-angle lens, the nearest point being very near to the camera, and the floor or foreground was to be included, he found it advisable to place the camera on a lower view-point than usual. The low view-point, of course, had to be selected with discretion.

Mr. Bennett went on to speak about copying, which by some was regarded as very easy work; yet he had been surprised to find comparatively skilled photographers fail at simple copying. It was purely technical work, and to photograph a drawing to scale was quite easy, but absolute accuracy was necessary, and nothing need be left to guesswork. With the help of lantern diagrams Mr. Bennett gave a detailed exposition of his own methods. He insisted that if copying was undertaken in a systematic manner, every copy ought to be a success. He had been surprised to find how little system there was in many establishments for copying; he himself had always regarded systematic exposure as an essential preliminary to success. Some time ago he had a commission to take a number of pictures in the National Gallery, and he found that the conditions of exposure, if represented by 1 on one side of the room, would have to be represented by 4 or 5 on the opposite side. This was simply because, although the room was lighted from the roof, the walls on one side were taken up so as to block the sky-light considerably. There was nothing to equal a

meter for guidance in exposure for copying under all manner of conditions.

In passing Mr. Bennett paid a tribute to the Bolt Court School, whose willingness to help and advise had been so very kind, he said, as sometimes to overwhelm him.

The photographer engaged on technical work should make himself familiar with colour sensitive plates and different screens; even a green screen at times might be exceedingly useful. The photography of machinery was difficult because oftener than not it was so placed in the workshop as to be ill-lighted from the photographer's point of view. In all apparatus taken in the workshop the photographer must be prepared to block out the background in his result. The best thing to use for this purpose he had found was opaque water colour; the most opaque was Indian red, and this, bought in tubes, made an excellent opaque for blocking out backgrounds.

Mr. Bennett dealt more particularly with mechanisms on railways, and described his experiences in signal cabins, when he had to give intermittent exposures. A signal cabin offered in its small space almost every difficulty with which the photographer could be called upon to deal. The windows particularly were always a source of trouble. He illustrated by the most painstaking diagrams and also by photographs how he placed his camera under these circumstances. His plan was usually to learn from the signalman which was the most frequent position for the signals, and to wait and give fragmentary exposures whenever that position recurred. Other unfavourable photographic environments were cathedral crypts and tube tunnels. To photograph in tube tunnels was not very difficult if only plenty of flashpowder were used.

Mr. Bennett went on to speak of photographing in country houses, particularly interior pictures, and illustrated how he managed rooms which were unsuitable either from the lighting or the spacing point of view, and then went on to speak of his cathedrals, showing how at Wells and Ely, for instance, where he had plenty of room to use a lens of longer focus, he deliberately chose the wide-angle lens, and got thereby a more pleasing result. He insisted upon the many advantages which the local photographer had over the visiting photographer, in respect to local knowledge, local access to unaccustomed points of view, and the opportunity to take advantage of seasonal variations.

Unhappily Mr. Bennett's lecture had to be greatly curtailed owing to the approach of the closing hour of the hall, and his slides were rushed through at a speed which did scant justice to their excellence. A hearty vote of thanks was accorded on the motion of Mr. St. George, seconded by Mr. T. C. Turner, who said that the remedy for a failing business was technical ability, and at no time was it so necessary as now for the photographer to be a good technician.

PHOTOGRAPHIC PORTRAITURE FROM A WOMAN'S POINT OF VIEW.

Certainly the most witty, and in some respects the most progressive lecture delivered to the Congress was that by Madame Yevonde on the above subject. The lecture was illustrated with lantern-slides of the work of some contemporary women photographers:—Miss Lena Connell, Mrs. Bertram Park, Miss Alice Hughes, Miss Florence Van Damm, Mrs. Angus Basil, Miss Dorothy Wilding, Mrs. Marion Neilsen, Miss Dora Head, Madame Pestel, of Eastbourne, Madame Genia Reinberg, of Paris, and Madame Yevondo herself. Following the lecture, Mrs. Frank Brown returned the compliment of the previous Monday evening by presenting Madame Yevonde with a bouquet of flowers.

Women have done much to popularise portrait photography. To say definitely how much is something of a problem, as it is always difficult to state accurately where an influence begins or where it ends. But I think we must all agree that portrait photography without women would be a sorry business. In fact, I would almost go so far as to say that it would have languished and died long ago but for the interest of women.

The mothers who wanted portraits of their sons; the daughters who must have pictures to give their affianced; the society beauties who must have a new photograph every time they buy a new hat, and last, but not least, the charming actress who must be photographed often and always. One could go on indefinitely with examples.

In fact, when we look round us and think how much our profession is influenced by feminine feeling, it is rather surprising that portrait photography is not considered almost entirely a woman's profession.

Women seem to possess all the natural gifts essential to a good portraitist, I mean the natural personal gifts, such as personality, tact, patience and intuition.

I was very glad on Monday night to hear our President, Mr. Frank Brown, make such a point of the necessity for right environment in taking the sitter. Atmosphere is a very strong factor, and one that most mere photographers have more or less ignored.

To my mind the sitter ought to be the predominating factor in a successful portrait. Men portraitists are often apt to forget this; they are inclined to lose the sitter in a maze of technique, and luxuriating in their cleverness and the beauty of their medium, they fail to remember that the living, breathing sitter is of equal importance, in my opinion slightly more so. As to the sitter's opinion (I can only guess at it), I should just like to ask you all how many times, in submitting a batch of proofs, has your technically perfect work been turned down; while some wretched under-exposed negative, a thing that makes you blush with shame, is acclaimed a masterpiece, because—"You have caught my expression; it is absolutely life-like; all my friends deeply love it." You groan in anguish as you write down the order for three dozen. And this truism is again brought brutally home "that the public does not care a rap about its prints as long as it gets a likeness." Now, we must not, of course, pander to the public in this respect; but, on the other hand, we must be equally careful not to forget them. And it is for this reason that I put the personality of the photographer as an important point.

A pleasant personality goes further towards the making of a successful portrait than a perfect print. The sitter must come first, and everything must be done to make him or her, and particularly her, as happy and comfortable in the studio as possible, or the odds are very much against a life-like portrait. A woman, to my mind, is much more likely to create this atmosphere than a man. Her tact and sympathy are acknowledged facts, and she ought to possess in a marked degree the power of putting the sitter at his ease.

Talking of that, I feel I must tell you a little story that Miss Lena Connell told me the other day, although it rather disproves my point about the tact, with a capital T, of the woman photographer, as she herself admitted, but it is too good to miss.

Miss Connell was photographing a very stiff, nervous man, who proved himself a most touchy and fractious sitter. After trying in vain to put him at his ease by conversation and cigarettes (although I am not sure about the cigarettes; I only guess at those) she at last lost patience with him, and said to him:—

"Why do you not go and get photographed by a man, as you appear so ill at ease, and foolish before a woman?" He became still more confused, of course, at that, and said:—

"Well, you see, it's like this, Miss Connell, I should look a silly ass any way in a studio being photographed, and I would much rather look a silly ass before a woman than before one of my own sex."

You might almost say here is another case for the woman photographer. If there are many sitters of the outlook of that gentleman, it is all to the woman photographer's advantage, even though it is not very complimentary to her.

The quickness with which a woman's brain works is an enormous help to her in dealing with sitters. Scientists tell

us that it tires more easily than a man's, but it acts spontaneously and with greater rapidity, which is a tremendous advantage in the studio, especially when dealing with children and difficult sitters. Our intuition here is of more value than man's much-prized logic.

Take the case of the sitter, and a very tiresome person she is too. Sometimes she is too thin, but, for argument's sake, we will pretend she is too fat. She insists on having full lengths, and has decided views on how she wishes to be posed, and she is quite sure that she does not want any of what she calls "touching up."

"Now, remember," is her parting instruction, "I want a photograph as I really am; I do not want to be made beautiful! I don't want to be touched up at all." Now, if you are foolish or only a little wise, or if you possess a cruel and over-developed sense of humour, you submit her rough unretouched proofs, and, of course, never see her again. If, however, you have a certain knowledge of human nature, you remove three chins, and show a slightly defined waist line and the suspicion of an ankle, and you send out proofs and hope for the best.

Back she comes in a very indignant mood. None of her friends will look at them—you have made her too fat; she knows she is rather plump, but not to this extent—why, you have given her a double chin: and see how broad you have made her across the face.

You sigh resignedly, and prepare for the unhappy business of photographing her all over again. This time you are very wise. You issue stringent instructions. All the superfluous chins must be removed; your retoucher asserts her skill and cunning in reducing hips, waist line, and ankle to at least normal proportions. Result—delight on the part of the sitter. Relief for the photographer.

Now, ladies and gentlemen, my point is that for nine women out of ten who come in and insist, as that sitter insisted on their desires for an untouched portrait, to look, in fact, exactly as they are, and not as they imagine they look—you may retouch as much as you like—reduce and beautify with all the skill of lead and knife—but the tenth woman really means what she says, and honestly wishes for a portrait with all her characters in.

Oliver Cromwell, you will, no doubt, remember, was a sitter of this nature. He was one of those, I am afraid, rare people entirely immune to the subtle art of flattery. "Warts and all," he commanded, the famous artist to whom he sat for his portrait. But the artist, thinking he would please Cromwell, forgot the warts. He did not know his man. "Either my true likeness or nothing at all," exclaimed Cromwell. And the next time the artist presented the picture the warts were painted in complete.

We do not get many female sitters of the type of Oliver Cromwell (and, incidentally, I might even add not many male); but we must be always on our guard, and for a woman with intuition it is by no means easy to spot the candid sitter. For a man I should think it would be an impossible, difficult task.

With children, women are at a great advantage over men. Many little sitters, on coming into a strange place, are naturally shy and a little suspicious of a man with ferocious whiskers perhaps (and quite a number of you men do wear ferocious whiskers). This alarms children—and then there are tears and sobs, and loud lamentations and expostulations. With only women in the studio the embarrassment of the child is not nearly so great.

This point is rather emphasised [illegible], which I believe is correct, that one of our foremost child photographers (a man) keeps entirely away from his [illegible]; he employs a woman assistant to talk to the child and keep them amused, while he watches unseen for the moment to expose his plate.

It seems, then, that the art of keeping the sitter—man, woman, or child—happy and interested [illegible] studio is a very important point in the production of real life-like portraits.

A fellow camera man told me once that he always wished he could study his sitters for half an hour in silence before starting to expose plates; and he regretted that this method was not possible owing to the fact that people would think him rude.

And I replied that even if his sitters excused his lack of manners, he would be dissatisfied with the method he was employing, as he would find that he had only been photographing a mere exterior; that after the lengthy contemplation he might and doubtless would and certainly ought to discover the best side of her face, the correct angle of her head, or whether she looked best looking up or looking down; but all the animation and sparkle of the sitter's personality would be lost in a fog of unhappy self-consciousness.

It ought not to take the photographer half an hour to make up his mind which is the better side of the sitter's face. Personally, I find it a good plan to ask the sitters themselves, and I nearly always get a correct answer. We most of us know our little peculiarities and blemishes only too well—incidentally we have a shrewd suspicion of our good points also, and sitters rather like to be asked, they think it is a good joke, and it starts a subject of conversation in which you interest them in the theory that in 99 cases out of a 100 the left side is more beautiful owing to the fact that careful mothers, when we are babies, put us to sleep on the right side, and the bones of the face being soft and unformed suffer accordingly.

I do not to-night intend to dwell for any length of time on the vexed question of the man v. woman assistant, as it does not seem to serve any very great purpose—further, the subject only a short while ago was well thrashed out by many able pens in a series of lively correspondence in the "British Journal." Personally, of course, I infinitely prefer the woman assistant; but, then, doubtless, I am rather prejudiced in her favour for obvious reasons.

The fact remains that she has grown steadily in numbers and efficiency with the growth of photography, and this, of course, is not a factor induced altogether by the war, as in pre-war days her popularity was just as noticeable.

In the reception room, of course, she has always reigned supreme. However much a man is master in his own studio, he invariably bows to the superiority of the woman receptionist. I don't believe there has even been a man receptionist—if ever there was one he must have been a very single failure, for no one has heard of him or followed his example.

But this question of the woman assistant is entirely a personal one—to be dealt with by individual photographers.

Now let us turn our eyes and see what the women photographers in other lands are doing. I had hoped to be able to procure a lot of information about them. And with this aim in view I light-heartedly set about collecting that information. I find, however, that the women abroad have not taken up portrait photography nearly so extensively as over here, with the exception, perhaps, of America, where numbers of good women portraitists abound, many of whom exhibit frequently at the salons and other exhibitions in this country, and whose work is doubtless familiar to some of you. Names, such as Mrs. Kasebier, Miss Charlotte Fairchild, Miss Mathilde Weil, and Miss Helen M. Murdoch spring at once to mind.

Apart, I repeat, from the United States, the woman portraitist does not seem to have made herself noticeable either by her numbers or the quality of her work—with the exception of isolated cases. This is very likely due to the fact that women abroad have not had the opportunity for self-expression and development that we have here now and that is possessed by women in America to an equal degree. This is a very important factor, which people sometimes forget in judging women's creative work in art. Isolated and exceptional women have always broken through the artificial sex barrier. That barrier makes it the exception always, rather than the rule, for woman to express herself any other way than through the traditional medium of the domestic circle. The dreams and aspirations of the majority of women found no means of direct self-expression at all.

In England, where women have so much freedom now, we find the best photographs. Abroad, in the countries where women are not so free, good women photographers are more rare. I told you just now that when I started collecting my facts I light-heartedly set out to search the world for the woman photographer. I am afraid I did not get very far. First, I tackled China, the most artistic nation in the world, and after inquiring from all sorts of people who had lived in China, or were reputed to have extensive knowledge on these matters, and getting nothing very satisfactory, I wrote to Mr. Tong, of the Chinese Legation but he could not say if there were women professional photographers.

In fact that never-failing fount of information our good friend Mr. Crowther, tells me that women have already started; but, like all beginners, they have much to learn, and their work is not of a high quality. In Australia there are numbers of excellent women photographers. In France the woman portraitist has not yet come into her own. I am greatly indebted to M. L. P. Clerc for the information I have to give you on the subject. He has taken a great deal of trouble in this matter. His "Paris Notes" are an interesting feature of the "British Journal" just now. He tells, for instance, this week, in a paragraph which is really the outcome of my inquiries, that although there are many talented amateurs, it is scarcely "possible to name half a dozen professional studios for portrait photography which are managed in Paris by women, and of this number barely half of them are run by Frenchwomen." This seems rather extraordinary when we consider how advanced France is in lots of ways. He also raises a point when he says that there are very few women retouchers (and all the best ones are foreigners). Perhaps the French temperament is not conducive to good retouching. But he mentions one woman, Madam Genia Reinberg, who kindly sent me some specimens of her work, which I will show you later on.

In Sweden and Norway the woman photograher is not so rare, and the two young daughters of that famous portraitist, Mr. Ferdinand Flodin, of Stockholm, are already beginning to carve out successful careers for themselves as portraitists.

So much for the woman photographer abroad. Here in England, while women have only just been privileged to sit on juries and in Parliament, we find that they have been closely connected with photography almost since its birth. They have, in fact, contributed largely to the rearing of and caring for the precious infant—both in the capacity of assistants and operators.

Mrs. Cameron, for one, was doing splendid work as far back as the sixties. She was a brilliant pioneer of whom we should all be very proud. Much of her work consisted of illustrating Tennyson's poems. Illustration by photographs had a tremendous vogue in those days, and there are signs that it may be coming back. So those of you who wish to be in the van of things—get busy! But to return to Mrs. Cameron. She photographed nearly all the eminent men and women of her day, and I am fortunate enough to be able to show you some slides of her work, including Tennyson, Browning, Carlyle and Darwin. I now want to read you a letter to Mrs. Cameron from a lady who wished for an appointment. My thanks are due to Mr. Crowther for procuring a copy of this letter to-night:—

"Miss Lydia Louisa Summerhouse Donkins informs Mrs. Cameron that she wishes to sit for her photograph. Miss Lydia Louisa Summerhouse Donkins is a carriage person, and therefore could assure Mrs. Cameron that she would arrive with her dress uncrumpled.

"Should Miss Lydia Louisa Summerhouse Donkins be satisfied with her picture, Miss Lydia Louisa Summerhouse Donkins has a friend who *is also* a carriage person, who would also like to have her likeness taken."

Other pioneer women whose names are almost household words—although they were working many years afterwards, of course—are Miss Alice Hughes, who is still going strong, and the late Madame Lallie Charles.

Miss Hughes's father was an artist, and she started her career about thirty ago by photographing his pictures when only a very young girl in her teens. Then she tried her hand at portraiture, and met with almost instantaneous success. People flocked to her studio, and she was easily the most popular photographer of her day. While still a girl, she was employing as many as sixty assistants, and averaging over sixteen sitters a day. She was the first to use the painted Romney background, which afterwards became so fashionable, and with it, of course, came the photographing of children with women in evening dress, at the time considered a great innovation.

The late Madame Lallie Charles attained a huge success. With characteristic boldness, she swept away all preconceived notions in portrait photography, and won fame by placing her sitters against a plain white background softly vignetted. This also had never been done before with any notable success. She was the possessor of a very brilliant personality, which must have contributed largely and aided her considerably in the accomplishing of her work

We have seen in the many exhibitions that are held up and down the country at various times, and more particularly in the beautiful examples on show at this present most successful exhibition of professional portraiture, that women possesses both originality and the creative feeling in the work. But we must also admit that she has her faults—and she has shown a certain weakness by falling too easily into the rut of the one idea. It is a failing all artists are prone to, and women more than men. I believe that this is due to the fact that we delight too much in keeping ourselves to ourselves.

Personally, this has been a great fault of mine in the past, I know. I had no idea what other people were doing, and it is only since I have come out a little that I have at all realised what an indifferent photographer I am. And that is a step forward, because until we realise that we have something to learn we can never progress. There are any number of women photographers who shut themselves up, as I have shut myself up, and refuse to join the Association or mingle in any way with the members of their profession. One woman openly boasted to me the other day that she had never in her life met another photographer before she met me. Now that is all wrong. We must come out and meet one another; we must join the Association; we must see one another's work and criticise, and, more important still, receive criticism; or we shall never improve. It is impossible to avoid becoming narrow and self-centred in our work if we barricade ourselves behind our camera and pretend that there are no other photographers in the world. Miss Dora Head said to me the other day: "It is so easy to descend to the sitter's level." I am afraid we inevitably descend to the sitter's level if, sooner of later, we do not take steps and watch ourselves very carefully. We must realise that perfection is not creation. That although we may have won fame by some special style or thought, to repeat ourselves indefinitely in this particular manner is not only non-creative and purely mechanical, but must eventually lead, if not to complete destruction, at least serious deterioration of our business.

The way of the photographer is full of pitfalls. It is different from any other profession in that there are so many high roads to success. One may find fame by beautiful quality of prints, another by the happy, natural expression and posing of the sitters, a third by an original scheme of lighting, a fourth by commercial ability and sound business training, and so on. It may puzzle the beginner to decide which of these roads to tackle. My advice is—tackle the lot. Find out your weak points, and see that they become your strong ones.

I have tried to show that personality, tact, patience and intuition are all very valuable to the portrait photographer; that women possess them to a far greater degree than men; that they are better with children, and that, of course, their inherent knowledge of clothes and eye for detail is a great asset in a profession in which these two play so important a part.

We know that there have been great women photographers; there will be still greater as women's mentality expands and improves with greater freedom and opportunity.

Her competition with men should prove helpful and invigorating to both sexes.

We also realise that she is liable to grave weaknesses; that she is often untrained; that having attained a certain amount of success, she does not bother to persevere and improve. She climbs to the top of the tree perhaps without much trouble, and then she shows a tendency to recline in comfort, never realising that there are other higher and perhaps more beautiful trees to be tackled, and that if she is not careful and refrains from further climbing, she may, after all, find that she has been left in the shade.

In conclusion, I should like to thank you all for listening so patiently. And particularly I thank the men for the kind manner in which they have endured this long discourse by a woman on how clever and altogether brilliant is her sex.

Further, I think I may say, and I am sure the ladies will back me up, that if any gentleman present would like to get up and say a few words on how clever is he and his sex, I am sure we will listen with enjoyment, although, mark you, there will not be any novelty in it, will there, ladies?

PHILONIE YEVONDE.

At the close of the lecture many graceful compliments were paid to Madame Yevonde by Mr. Speaight, Mr. Marcus Adams (who was thankful he was not a ferocious, whiskered man), and Mr. Herbert Lambert, who said that a cloud was upon him because he felt that photography, like other artistic pursuits, would in the long run pass out of men's province altogether. Still, he believed that co-operation and not rivalry between the sexes was the thing to be sought after. Mr. Frank Brown, who urged that ladies should be introduced on to the Council of the P.P.A., with Madame Yevonde as the first lady member, protested that he had been misunderstood about the flowers. It was too much that he should be accused of having spoken slightingly of flowers—he who had left his bed at one o'clock on a cold and frosty morning to bring six and twenty chrysanthemum plants into the greenhouse!

A vote of thanks was carried with much acclamation, and Madame Yevonde briefly replied.

A LUBOSHEY NIGHT.

On Thursday evening Mr. Swan Watson presided over a crowded Congress Hall. Mr. N. E. Luboshey had been announced to give a talk about Continental studios and methods, but he began by saying in his vivacious way that he had been given *carte blanche*, and that slides had been suddenly demanded, so that at the last moment he had procured some mixed slides, which he had only exhibited once in his life, and that for the purpose of giving a demonstration of the effects of plain lighting.

Mr. Luboshey proceeded to show a most interesting series of photographs of well-known gentlemen taken at a meeting of the Royal Photographic Society without any of the paraphernalia of the modern portrait studio. He created much amusement when specimens of fancy lighting were thrown on the screen by remaking, "I was asked to do it, but I don't want to look at it." What he believed in was straightforward, honest photography. He showed what could be done without any manipulation of the light whatever, simply by changing the position of the sitter in relation to the lens and the light. He took 27 negatives of one lady, all on the same day, and not one was anything like the sitter! Mr. Luboshey added that every time he had the opportunity he emphasised the necessity of providing direct and simple lighting. Among his results he exhibited a stage scene, taken by ordinary stage lighting, and said that the difficulty of doing this sort of thing simply did not exist. Some beautiful Greek tableaux photographed in Russia came next, and in one of these examples Mr. Luboshey had combined half-a-dozen negatives, so that the same performers were repeated in the one tableau. This, he said, was a branch of photography little touched on, but with a great deal of business in it if done well. The exposures were made by means of an electric lamp which he held in his hand while standing on a ladder, and were quite short. The secret of the whole thing was to get the sitter to work with the photographer, and also to have enough light and to know where to place it.

One of Mr. Luboshey's group photographs showed a crowded meeting of the Royal Photographic Society, taken by the ordinary lights of the room. The room contained eight 300 c.p. half-watt lamps. Portraits of individuals were also projected, attention being drawn to the sparkle of the eye. Referring to his experiences abroad, Mr. Luboshey had much to say with regard to the fine work done in Scandinavia by pioneers who upheld the highest ideals of the profession. With his usual enthusiasm he insisted on straightforward work and the folly of straining after artificial effects. He did not think that artistic portraiture, great as had been the progress in technique, was up to the level of thirty or forty years ago, and this was due to the defection of so many from the straight path.

The Chairman remarked that they had yet another treat in store, for Mr. Flodin, the most prominent photographer in Sweden, to whose work Mr. Luboshey had referred, was attending the Congress, and would speak to them.

Mr. Ferdinand Flodin, who was introduced by Mr. Luboshey as a professional photographer who never failed to study every new method and to bring every discovery to the notice of his brethren, was enthusiastically received. He spoke in excellent English, though he said he had never in his life before stood before an English audience. He had come to England solely for the purpose of assimilating new ideas. He had been on the same platform with Mr. Luboshey on several occasions. Once, in a certain town in Sweden, Mr. Luboshey started at nine o'clock, and was still talking at two o'clock in the morning without being tired in the least. Their brilliant lady lecturer on the previous evening (Madame Yevonde) had mentioned his (the speaker's) daughters. One of them had fallen—quite willingly—into the matrimonial trap, but the other was still at home, trying to beat her father's work. The work of the photographic societies in the various countries was very much the same as in England, though here, of course, it was on a much larger scale. In Sweden they had a comparatively big Association—the Svenska Fotografernas Forbund—which had been in existence for 25 years, and last year, to celebrate that anniversary, a very good exhibition was held at Stockholm, representing the work not only of Sweden, but of Norway and Denmark, and including not only a professional section, but an amateur section, a historical section, and a scientific section. A selection was made from the artistic work shown there, and the pictures were exhibited in turn at Copenhagen and Christiana. He thought it would be a very good thing if people from other lands had the opportunity of coming to Congresses of this kind, so that they could study the latest improvements and select what was best. In a little land like Sweden naturally they had no factories, and almost all their materials came from foreign lands. A good quantity came from England, but some English articles were not so well known as they should be. Perhaps some English manufacturers did not think it necessary to spread new knowledge in these small countries, but it might be a good thing for them to do so. The name of England had been made famous in the photographic world by the work of many, and to the pioneers he paid homage. He added that he would try to

take back to his professional brethren the valuable information he had obtained at the Congress, and on another occasion he would try to bring some of his confrères.

Mr. Luboshey, having been warmly thanked for his lecture, said that he owed all he knew to what he had picked up in his travels from the famous photographers whom he had been privileged to meet. Unfortunately, he was not now in touch with professional photographers as formerly, because he had devoted his attention to the scientific side, and more particularly to X-ray work. "We are always thinking," added Mr. Luboshoy, "that we are great artists, and we certainly want to be: but I can assure you that to be an artist is about as far from being a photographer as heaven is from earth. I started as an artist, and I have given it up. Twenty lives like mine would not make one artist. But I did find that if you studied æsthetics and trained your eyes to all that was beautiful, you might become an excellent professional photographer, and exhibit such real art as to put the painter in the corner for shame. In the countries in which I have travelled there is not one photographer or assistant who has not studied drawing from life or who has not passed through a drawing school. There is not even one retoucher who has not done so. When I was a child I studied drawing, my teacher being a Bohemian, and I have always believed that even if a shoemaker knows drawing, he can make better boots." (Applause.)

PSYCHOLOGY IN THE STUDIO.

Mr. C. P. Crowther, F.R.P.S., gave an exceedingly interesting lecture on "Psychology in the Studio," Mr. Marcus Adams occupying the chair.

In introducing the subject, Mr. Crowther said that the whole point of his lecture to them that day was that the things we did unconsciously we did better than the things we did consciously. That was a sound paradox. The small child began by walking consciously and made a poor thing of it, but when it could walk and run well its movement was unconscious. When a photographer posed a sitter in the old-fashioned way in a chair, saying, "One moment, please—steady—steady!" and so on, the sitter became painfully self-conscious, and very probably complained of the result afterwards, though an exact likeness as he appeared then might have been produced. It was certainly better to follow the example set by Mr. Luboshey in his lecture the previous evening, and move freely about, without indulging in too much careful analysis and measurement. People said, "But you must be thinking." Well, a man might read any amount of books about golf, but he did not think of them when he was on the links. A pianist who was giving a wonderful recital did not analyse the millions of notes he played. When an artist was painting he might destroy the very soul of his picture by over-much daubing and touching and changing.

Mr. Crowther believed that psychology in the studio might be so developed that the sitters could be got into the required mood which would reveal their very characters. When in the East he had the privilege of a sitting from Sir Rabindranath Tagore, the Indian poet, and the latter readily agreed to sit in meditation, doing this quite naturally, so that very nice pictures were secured. It might be said that this was conscious, but this he would not admit. There was a soul in every sitter which they must all try to catch, and there should be no unnecessary intrusion of artificialities to annoy or disturb the sitter. For his thought and trouble the photographer might not always be recompensed in money, but he would receive honour, and he would have the pleasure of knowing that his work was appreciated, which was, after all, far more important than the shekels.

Mr. Crowther proceeded to relate one of O. Henry's famous stories about a great painter who was able to depict the character of his sitters so vividly that those who saw the portraits instinctively trusted or mistrusted the subjects. It was difficult, of course, and it need not be said that no one would think of dealing with an æsthetic lady in the same way as with a butcher. But the great thing was to have sympathy with the sitter and to depict the character as well as possible. If this was to be achieved, one must not depend overmuch on the retoucher. The aim should never be to do things as quickly as possible and get the sitter out of the place. It must be acknowledged that the status of the photographic studio owed not a little to amateur workers who did their work with leisure and freedom, and who had had a certain education both in art and in social matters, so that they produced a class of picture which received the stamp of recognition from the people best able to pay a good price.

Mr. Crowther, in further harmony with much that Mr. Luboshey had said the previous evening, proceeded to read the following sonnet, "To a Photographer," by Barton Braley, the sentiment of which was heartily applauded:—

> I have known joy and woe, and toil and fight;
> I have lived largely, I have dreamed and planned,
> And Time, the Sculptor, with a master hand
> Upon my face has wrought for all men's sight
> The lines and seams of life, of growth and blight,
> Of struggle and of service and command;
> And now you show me This—this waxen, bland,
> And placid face—unlined, untroubled, white!
> This is not I—this fatuous face you show,
> Retouched and prettified and smoothed to please.
> Put back the wrinkles and the line I know
> I have spent blood and brain achieving these
> Out of the pain, the sorrow, and the wrack.
> They are my scars of battle—Put Them Back!

Mr. Crowther proceeded to show about fifty slides, contributed by members of the profession, most of which were heartily applauded. They included some very beautiful child studies. In several of the examples Mr. Crowther pointed out a defect in that the sitter's hand, raised to the face, was far too large and prominent, detracting from the character in the face, which should be the important point. He also showed some striking examples of combination work, and of the fancy lighting so much detested by Mr. Luboshey, and concluded with his own interesting studies of Sir Rabindranath Tagore.

Mr. Marcus Adams said that the psychological aspect was important, but it was not everything. It was possible to be such an enthusiast for psychology as to forget to put in the plate or squeeze the bulb. With the power of which Mr. Crowther had spoken there must be practised all the time a certain restraint. It was necessary to do more than get the just-right negative; it was necessary to produce the print. Success could only be attained by perseverance, and personally he had learned more from his failures than from his successes. Little details of environment had a good deal to do with the result. In dealing with children, for example, a dusty camera or a dusty toy would upset his equilibrium. Only the best should be placed before a child. A child was not necessarily frightened by a photographer's ferocious whiskers or bushy hair, but looked right into one's character to a far greater extent perhaps than the photographer realised. Some years ago he found that he himself possessed this psychological power with children. No praise was due to himself; it was a God-given endowment, and it was only his duty to use it. That was his principle in his profession.

Mr. T. C. Turner remarked that it was of the highest importance that personality should be studied. The man or woman who studied merely the physical appearance was bound to come to grief. Incidentally, he believed in studying the great portraits in the Wallace Collection and other galleries, in addition to photographic exhibitions. While there must be a likeness, no little of the success of professional photography depended upon dexterity with brush and

pencil. He agreed heartily with Mr. Crowther in deprecating as a crippling influence the pursuit of one's profession for the sake of money.

Mr. Crowther, who was cordially thanked for his lecture, said, in reply, that he hoped they would all strive to do something better beyond the ordinary "bread and cheese stuff," so that they might have the joy of hearing others say, "How beautiful!"

THE ANNUAL DINNER.

A large company, including officers and members of the Association and many leading people in the photographic trade dined together at Gatti's Restaurant on Friday of last week, Mr. Frank Brown, president in the chair. Following the toast of "The King," that of "The Professional Photographers' Association" was proposed by Dr. G. H. Rodman, President of the Royal Photographic Society, who alluded to the growth in membership and financial stability of the P.P.A., and expressed his pleasure at the closer association between the P.P.A. and the R.P.S. That closer bond was signified by the election of Mr. Lang Sims to a place on the Council of the Royal Photographic Society, an appointment which, he thought, would be of mutual benefit to the two societies.

Mr. Frank Brown, in replying, expressed his firm belief in the future of the Association It had done a great deal during its twenty years of life, and particularly during the past four or five years. He looked forward to an extension of their personal relationships with professional photographers in America. He thought a delegation might take part in the great congresses which were held in the States; and he also welcomed the idea of exchange of sentiments and experience with their professional confrères in France.

Mr. George Hana had some characteristically nice things to say in proposing the composite toast of "The Ladies and the Visitors."

Madame Yevonde made a neat little speech in replying for the ladies. She deplored the absence of a woman from the Council of the P.P.A. But for that, the horrible congress button or badge would not have been issued. The women members could not possibly attach it to their garments. It was not a thing they would care to use as an article of dress, and she had purposely lost hers.

Mr. F. C. Mattison, in replying for the visitors, said that as head of an industrial undertaking dealing with photographic supplies, he was glad to witness the continued prosperity of the P.P.A. He would not conceal the view that the welfare of firms which supplied a considerable part of their outputs to portrait photographers had in that measure a common interest in the prosperity of the latter; and simply for that material reason manufacturers were glad of the opportunity of forwarding the interests of the Professional Photographers' Association.

Mr. Arthur C. Brookes also responded for the visitors, and expressed his pleasure at being present.

The toast of the officers and council of the P.P.A. was proposed by Mr. E. Drummond Young, who coupled with it the name of the secretary, Mr. Lang Sims, who, in his reply, outlined possibilities of congresses on a larger scale in future years.

Mr. H. A. St. George, in proposing the toast of "The President," dwelt very happily upon the qualities which had endeared Mr. Frank Brown to his fellow members during his year of office and the Congress week. He asked his acceptance of the replica of his badge of office, and of an address thanking him for his many services.

Mr. Frank Brown, in return, expressed his happiness in the position he had occupied, and then proceeded to transfer his badge of office to Mr. A. Swan Watson, whose acknowledgments of the honour done him in his election brought the proceedings to a close.

Excursions.

Despite the curtailment of railway facilities the Kodak Company arranged for members of the Congress to reach the Harrow Works in scheduled time, conveying them thither by a number of chars-à-banc. At Harrow the visitors were royally entertained to luncheon, and were then taken in parties through sections of the works under the guidance of heads of departments at Harrow and Kingsway. The group of members was photographed during the visit by Messrs. Panora, Ltd., and groups of the Council were also taken by members of the Kodak staff. Negatives were immediately developed in the Kodak workrooms, and a team of Eastman projection printers put into use for the rapid production of prints.

The large group, made with a "Cirkut" camera, is reproduced on another page in this issue, where, however, owing to the large claims upon our space by other proceedings of the Congress, it is placed in an advertisement section.

The visit to the Guildhall on the previous day was the occasion of a considerable gathering of Congress members, who, under the guidance of Alderman Sir Louis Newton, inspected the historic building.

PRINCIPLES AND MECHANICS OF MOUNTING.

(Report of a lecture before the Croydon Camera Club by Mr. Vivian Jobling.)

The club is fortunate in having among its members many of mechanical bent, for photographic societies cannot live alone on the eternal cycle of pictorial dissertations without surfeit, or mainly on lantern-shows without atrophy; stock demonstrations for the beginner must necessarily be limited; scientific papers are Greek to the majority, and new processes and procedures rival total eclipses in their frequency. Almost equally rare is the scientist who can, or will, deign to descend to the level of the ordinary run with popular expositions of the recondite. But the mechanical man introduces variety in many directions, usually having a host of things up his sleeve either directly or indirectly connected with photography, and, moreover, can show "how it is done," ever of interest, even if one cannot hope to go and do likewise.

Of this sort is Mr. Vivian Jobling, who recently highly interested all with a capital lecture-demonstration on "The Mounting of Photographic Prints," a model of orderly sequence. The purpose of mounting, he said, is to separate the print from its surroundings, to provide an appropriate setting, to bring out by emphasis its good qualities, or minimise any imperfections. Simplicity is to be aimed at, and consequently the mount should never compete with the print for first attention by being too ornate or elaborate, or overpower it by being too heavy. In most cases the mount

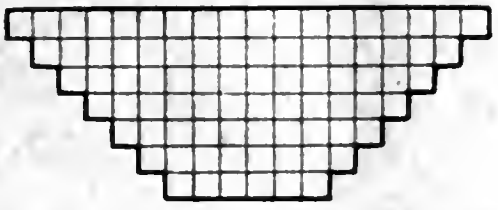
should harmonise with the tint of the picture, unless colour contrast is desired to emphasise its tone. Generally speaking, the mount should not be lighter than the highest lights, nor darker than the deepest shadows. There are, however, cases when it is advantageous to lower the former by using a lighter mount or to lighten the latter by employing a darker.

A perfect print of steel-engraving quality can be placed on mounts ranging from white to black without error, other conditions being favourable, but few photographic prints can stand either extremes; also, a mount of the same prevailing tone as the picture is rarely effective. Finally, he said, never do a thing merely because it is the fashion, for such a course is fatuous. The present-day almost unlimited choice of mounts is sufficient to satisfy all needs. Very suitable for the rough usage prints are subjected to in circulating portfolios are hand-made mounts.

The adoption of a standard size will be found useful for storing in portfolios or substituting prints in frames, especially so if the ratio 1 to $\sqrt{2}$ is employed, as suggested by Mr. Watkins for dry-plates, for the mounts can then be halved without altering the relative proportions of length to breadth. Music size (14 × 10) fulfils this condition, and corresponds with commercial cases and portfolios.

When placing a print on a mount more margin should be allowed at the bottom to prevent the familiar "dropping" effect—considerably more when it is desired to suggest space below, as in a bust portrait or large head. To emphasise a panel effect allow less at the sides than the top. Lateral decentering is generally undesirable, though in the case of unbalanced prints, or to break too even symmetry, the device can occasionally be employed.

An ingenious and easily-constructed contrivance, devised by the lecturer, for correctly placing prints on drawing mounts was shown, and is indicated in the figure. A drawing, slightly longer than the largest mount in use, is made on squared paper and cut out. It is laid close to the top of the mount and parallel with it and centered laterally, which is effected



at a glance. The print is then adjusted to the guide, the latter slipped from under, and two pencil dots made at the upper corners of the print, so that after the adhesive is applied it can be laid down again in identical position. Mr. Jobling's guide was much longer, and had many more and shallower steps than shown in the figure, which, however, sufficiently illustrates the principle.

Border-tints, he said, should only be used for a definite purpose, the over-ornate being carefully avoided. They have value when the mount chosen is of the predominant tone of the picture, for here a lighter or darker border-tint separates print from mount and prevents one merging into the other. Also, a darker border-tint will brighten the high-lights without suggesting the heaviness which a mount of the same depth may introduce. Similarly, a light border-tint can be used to lower the high-lights when a light mount may be too powerful. A slight variation of colour in the border is also often useful to counteract or emphasise the colour of the print.

Mr. Jobling then passed on to a review of the various methods and adhesives employed in mounting, favouring attachment at the top edge of the print. Dry-mounting was, of course, ideal, and, in the absence of a press, a flat-iron—the heavier the better—may be employed. Personally, he had not been very successful when using a flat-iron with commercial tissues, and made his own, which never failed. He employed a formula given some years ago in the "Photographic Annual," but with modifications which meant all the difference between success and failure. The amended formula is as follows:—

A.

Orange shellac	4 ozs.
Methylated spirits	6 ,, (fl.)

B.

Gum Elemi	1 oz.
Canada balsam	1 ,,
Methylated spirits	8 ozs. (fl.)

Dissolve separately and mix, when the solutions will be found to bulk to about 18 ozs. The Canada balsam is the thick solution (of greater viscosity than golden syrup) stocked and supplied by chemists.

Japanese tissue, obtainable in sheets 11 × 8½, is dipped sheet by sheet in the mixture, surface liquid removed by dragging the sheet against the edge of the dish, and hung up to dry. A convenient way of doing this is to cut some narrow strips of common strawboard and range them one over the other in narrow staircase fashion. Adhesive is applied to the "stairs" with a brush, when each strip will readily pick up a piece of the tissue. In answer to a question, he said the tissue is sold by most stationers for copying letters, the pre-war cost being 2s. a ream; that of the solution 1d. an oz.

In the discussion Mr. H. P. C. Harpur modestly intimated that he was content to take a back seat in the mechanical line when Mr. Jobling was concerned, and then as a corrective immediately superimposed himself on lecturer and audience on various art aspects. He insisted that fashion is a most powerful asset in the art business. It powerfully governs the tonality, shape, and size of pictures, mounts, frames, collars, neckties, jumpers, and strikes; in fact, he said, fashion is so powerfully powerful that all are powerless to avoid it. Mr. E. A. Salt, whilst recognising the great improvement effected in recent years in mounts, had never come across any of a really neutral grey of British make, though he had seen some hailing from the other side of the Herring-pond. Mr. L. J. Hibbert, from a scientific standpoint, reproved Mr. Jobling for not having spectroscopically examined the light reflected by mounts, and was in turn chided by Mr. J. W. Purkis for overlooking sources of variability. The chairman, Mr. A. F. Catharine, after some terse allusions to these scientists, proposed a hearty vote of thanks to the lecturer, which was carried most heartily.

PHOTOGRAPHIC DEALERS' ASSOCIATION.

The annual meeting of members was held in the Congress Room at the Photographic Fair on Monday, April 18, 1921.

The honorary secretary, Mr. A. Oglesby, in presenting his report of the year's work, stated that there had been a considerable increase in the membership of the Association during the past year.

During the year, the Association has dealt with complaints of dealers allowing members of photographic societies and others discounts off their purchases, and has in all cases succeeded, with the assistance of manufacturers, in getting the offending dealers to withdraw the concession and give a written undertaking that the practice would be permanently discontinued.

As a result of representations to the principal manufacturers that a maximum discount off apparatus and accessories should only be allowed to *bona fide* dealers, and a lower rate of discount to professional photographers and other firms using photography for trade purposes, a schedule of traders to whom discount should be allowed has been agreed upon.

The minimum scale of developing and printing prices recommended by the Association has, with few exceptions, been adopted throughout the trade.

The possibility of co-operative societies opening departments for the sale of photographic apparatus and accessories has been brought to the notice of the executive committee. In view of the importance of this question, it was decided to bring the matter forward for discussion during the annual Congress.

Other questions of importance to retail dealers have been con-

sidered during the past year, and steps taken to remove the causes of discontent.

It was suggested that the members' subscription be raised to £1 1s. per annum, but after considerable discussion, it was decided not to recommend any alteration for the time being. It was, however, agreed that the executive committee should consider the possibility of submitting to members a scheme for trade and associate members, the latter to include chemists etc., who only handle photographic supplies as a side line.

It was decided that the thanks of the Association be tendered to Messrs. W. Butcher and Sons, Ltd., for placing space in their "Camera House Journal" at the disposal of the Association.

The following were elected officers of the Association for the ensuing year :—

President, A. Oglesby (Sands, Hunter and Co., Ltd.).
Vice-President, W. E. Heaton (Wallace E. Heaton, Ltd.).
Hon Treasurer, J. E. Hodd (Westminster Photographic Exchange, Ltd.).
Hon. Secretary, E. H. Ayling (Horne's Camera Exchange).
Council, J. A. Sinclair, G. W. Mann, A. J. Leather, G. F. Horne, London members.
Provincial members, J. Ireland, Chester; F. V. A. Lleyd, Liverpool; A. E. Briggs, Manchester; C. R. Pinchbeck, Hull; G. W. McIntosh, Sheffield; F. W. Doughty, Hull; V. E. F Walker, Brighton: Halksworth Wheeler, Folkestone.

A Congress of Dealers was held on Wednesday, April 20.

Several members spoke strongly against the principal camera manufacturers opening fresh accounts with small retail traders in districts already well served by established dealers, the general feeling of the members being that by so doing, the manufacturers are not doing justice to their established customers, and in some cases their goods are not being sold under conditions which are likely to prove beneficial to the industry as a whole. It was suggested that manufacturers should consider the desirability of ensuring that new accounts should not be opened unless persons fully qualified to explain photographic apparatus and manipulations to prospective purchasers be placed in charge.

The question of co-operative societies being recognised as dealers, created a lively discussion. Many members complained that although comparatively few co-operative societies are yet handling apparatus, they are supplying plates, papers, etc., on which members get a dividend on their purchases. The following resolution was passed, and the secretary was instructed to forward a copy to the British Manufacturers' Association :—

> "This meeting of members of the Photographic Dealers' Association protests against co-operative societies being supplied with photographic apparatus and accessories, plates, papers, etc., and all price-protected goods, to co-operative societies, except on the terms stipulated by the Proprietary Articles Trade Association."

On Friday, April 22, a well-attended lecture on "Window Dressing as a Selling Force, and its Application to the Photographic Trade," was given by Mr. E. Willson, of Messrs. Kodak, Ltd., and winner of the £100 prize in the National Window Dressing Competition at the Advertising Exhibition, 1921.

It was unfortunate that owing to the threatened strike of railway workers, some of the most interesting events of the Congress had to be abandoned, and in view of the outlook a day or two prior to the opening of the Photographic Fair, the executive committee thought it would be unfair to the Houghton-Butcher Manufacturing Co. and Messrs. Ross, Ltd., to proceed with their arrangements, as no guarantee could be given of the number of dealers likely to be present.

For the same reason, the annual dinner of the Association had to be cancelled, much to the regret of the dealers present at the Congress and the trade generally.

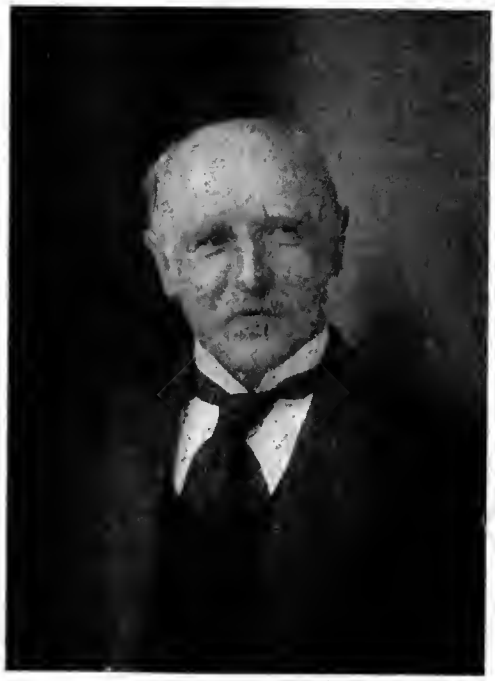
PIVOTAL POINTS.—Under this title Messrs. Burroughs Wellcome have just issued a very instructive 24-page booklet for the amateur worker dealing with exposure, development, and printing. It describes the use of the Wellcome exposure calculator, time methods for development with "Tabloid" chemicals, and the merits of "Tabloid" toning and other preparations as regards certainty of effect. The booklet may be had free on application to Messrs. Burroughs Wellcome, Snow Hill Buildings, London, E.C.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

THE NEW PRESIDENT.

To Mr. Swan Watson, who attended the Congress as president-elect of the P.P.A., must be ascribed the *bon mot* of the proceedings of the week. Alluding, at the annual dinner, to the handicap which the distance from Edinburgh to London placed upon his taking a share in the counsels of the Association, he said that he thought the distance from London to Edinburgh must be a good deal less, judging from the visits paid to it by photographers in the southern metropolis. This humorous thrust at the occasional invasion of Edinburgh by photographic firms offering "free sittings" scarcely evoked the oral appreciation it deserved.

Mr. Swan Watson has been in business in Edinburgh as a professional photographer for nearly 30 years, and has largely been a photographer of men. The Scottish capital, rich in its society of learned professors, surgeons, and doctors, solemn Presbyters, and leaders of industry, has provided him with plenty of subjects, and has developed in him an art of masculine portraiture which owes nothing to freak effects, but is based on a shrewd reading of character and a sense of the qualities which go to make an effective portrait of a man. The war, by removing many of the Edinburgh men folk from the city, sent, in compensation, their wives and



Portrait by Alexander Corbett.

MR. A. SWAN WATSON, PRESIDENT, P.P.A., 1921-1922.

daughters to Mr. Swan Watson's studio, and gave him the opportunity of showing his art in a lighter and very delightful vein.

The new president of the P.P.A. is a strong believer in the apprenticeship system. He was apprenticed himself, and in his own business makes it a custom to allocate the four years served by an apprentice, two of them to the learning of lighting, posing, etc., in the studio under his own direction, and the other half of the time about equally betweeen carbon printing, Platinotype or Kodura printing, and retouching and finishing. He holds strongly to the view that the present difficulty of getting thoroughly qualified assistants has its cause in the fact that many have not served a proper apprenticeship.

Continental travel has been one of the æsthetic influences in Mr. Swan Watson's life. For many years he has spent a vacation, chiefly in Italy, and there, particularly in the study of art collections in Rome and Florence. His lectures on Italian art have been delivered to many educational and literary societies. His other hobbies are music and trout fishing. A president of parts, whose contributions to next year's Congress may be expected to be substantial.

We are much indebted to Mr. Alexander Corbett, of Baker Street, for the accompanying portrait of Mr. Swan Watson, taken a few days ago.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, MAY 1.

Hammersmith (Hampshire House) Phot. Soc. Outing to Egham.

TUESDAY, MAY 3.

Royal Photographic Society Colour Photography. H. S. Watkins.
Manchester Amateur Phot. Soc "Development Methods I have Tried." E. N. R. Hurt.
Portsmouth Camera Club. Affiliation Portfolio of Prize Competition Prints, 1919.
Scottish C.W.S.C.C. (Glasgow). "Portraiture." R. Chalmers.

WEDNESDAY, MAY 4.

Accrington Camera Club. "Photography: Its Present-day Importance and Power." A. Dordan Pyke.
Croydon Camera Club. Lecture. W. L. F. Wastell.
Edinburgh Photographic Society. Leicester and Leicestershire Photographic Society Portfolio.
Rotherham Phot. Soc. "Marine Photography." F. J. Mortimer.

THURSDAY, MAY 5.

Hammersmith (Hampshire House) Photographic Society "Personal Practice in Pictorial Printing." E. C. Perry.
Kryn and Lahy (Letchworth) Phot., etc., Soc. "The Manufacture of Anastigmat Lenses."

FRIDAY, MAY 6.

R.P.S. Pictorial Group. "Rendering of Sunlight." Miss Warburg.

SATURDAY, MAY 7.

Bradford P.S. Excursion to Hewenden, Harden, and Goitstock.
Hammersmith (Hampshire House) Phot. Soc. Outing to Wimbledon Common.
Scottish C.W.S.C.C. (Glasgow). Outing to Bridge of Weir.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, April 26.

The occasion was a lecture on the life and work of Sir Wm. Abney by Mr. Chapman Jones, and the President, Dr. G. H. Rodman, said he felt it would be the wish of members that the chair should be occupied by Mr. W. B. Ferguson, whose investigations had been in the same field.

Mr. Ferguson, in accordingly taking the chair, explained that the Council had been unanimous in asking Mr. Chapman Jones to undertake the important and difficult task of reviewing the work of their former president.

Mr. Chapman Jones first sketched the official life of Abney, and indicated the great services rendered by him in the improvement of methods of teaching science. He outlined his purely scientific investigations, and considered in greater detail his contributions to progress in photography. He emphasised the fact that Abney stood alone among scientific men in having devoted himself to photography as a science at a time when everybody looked down on science and science looked down on photography.

The continuing action of light in bichromate printing was not discovered by Abney, but he made useful what was considered a bugbear of the carbon process. In the course of his work on emulsions, he discovered gelatino-citro-chloride or P.O.P. paper. In adding hydroquinone to photographic developers, he provided one which could be used without a restrainer; another also due to him was ferrous citro-oxalate.

Abney's studies of the failure of the time-intensity law, including that of intermittency, in the action of light on photo-sensitive materials were brought before the R.P.S. in 1893. His researches on the measurement of the speed and efficiency of shutters were pioneer work which found expression also in his experiments in direct heliochromy and in three-colour photography.

His greatest self-contained work was his preparation of emulsions sensitive to infra-red, done a few months after Vogel's discovery of orthochromatism, and bringing to light the behaviour of numerous colourless colour-sensitisers, and even the production of infra-red sensitiveness without a sensitiser. The results were collected in the Bakerian lecture at the Royal Society in 1880.

Declaring Abney to be the "father of quantitative photography," Mr. Chapman Jones described his instruments for the measurement of opacity and other properties of negatives and plates, and dwelt upon his early use of graduated wedges in sensitometry.

Mr. Ferguson, in proposing a vote of thanks to the lecturer, alluded to the discourse as "a great lecture on the great work of a great man," and the audience, which included Lady Abney, endorsed his opinion by acclamation.

Commercial & Legal Intelligence.

NEW COMPANIES.

KINEMATOGRAPH INVENTIONS, LTD. — This private company was registered on April 21, with a capital of £10,000 in £1 shares. Objects: To acquire all the patent rights of H. Workman in certain inventions relating to cinematograph and photographic work, and to carry on the business of manufacturers of and dealers in all kinds of cinematograph machines and appliances for the production of moving pictures, etc. The first directors are: W. S. Workman, 75, Bothwell Street, Glasgow; W. O. Workman, 5, Crown Terrace, Glasgow; G. A. Workman, 75, Bothwell Street, Glasgow. Secretary: R. McNair. Registered office: 21, Ironmonger Lane, E.C.2.

News and Notes.

A RECORD YEAR FOR PATENTS.—The work of the Patent Office last year (1920) was a record for any twelve months since the institution of that office. It is stated officially that the great increase in the work of the office was caused, to a considerable extent, by the filing of a large number of applications from abroad under the provisions of the Treaties of Peace. The total number of applications for the year was 36,672—over a hundred per day—by far the largest number received in any one year, and an increase of 3,819 as compared with the previous year. Women inventors sent in 311 applications, an increase of five on the previous year (1919).

PHOTOGRAPHS OF DOGS.—The National Canine Defence League, of 27, Regent Street, London, S.W.1, is anxious to have good photographs of dogs for illustrating its publications, and offers five guineas for the best photographs sent in before the end of June, 1921. The quality most desired in the picture is that of expression. For this reason the pictures should be taken "close up." Groups of dogs are eligible, but those typifying the qualities of faithfulness will be most welcome. Winning pictures become the property of the League, whose decision will be final. Those desiring the return of their prints must enclose stamped addressed envelopes.

WASHING PRINTS.—Mr. C. S. Baynton, Exchange Buildings, New Street, Birmingham, writes: "You published an article in the 'B.J.' last week, on washing prints, written by Mr. A. G. Willis, who appears to be rather behind the times, in so far as apparatus is concerned. He apparently has not been to the Photographic Fair or heard of Baynton's 'Turbine' print washer, for he says there is no mechanical print washer that will separate the prints and wash them thoroughly. In this he is wrong, and I shall be very pleased to send him one to try if he will kindly write to me. His suggestion that it saves time and labour to use sinks and tanks also is wrong, as it requires labour to do it, and my washer requires no attention at all."

GRABER PRINTING MACHINES.—Mr. Ellis Graber, of Tunbridge Wells, has just published a large new illustrated catalogue of the machines and installations made by him for quantity production of photographic prints as regards exposure, development, fixing, washing, and drying. These machines are of various types, according to the requirements of the user, and provide the means of a very rapid output of prints by the thousand or million. Having

had several opportunities of seeing for ourselves the excellence of their design and workmanship. we are not surprised to observe in the catalogue the many testimonials from firms and institutions employing them, and to notice that they have been supplied to the British. American, and Italian Governments.

THE PICTURE POSTCARD INDUSTRY IN GERMANY.—Conditions in the German picture postcard industry do not appear to be particularly encouraging, this branch of trade probably having suffered more from the general increase in prices than any other German industry. One concern after another has been forced to discontinue that line of business. The situation is traceable, writes the representative at Berlin of the U.S. Department of Commerce (in the Journal of the Royal Society of Arts), not so much to increased wages and cost of raw material as to the Government's increase of postage on postcards from 5 to 30 pfennigs, with the resultant decreased demand for the cards.

Prior to the war, the monthly average of picture postcards manufactured in Germany under the phototype process was 32,000,000. By the end of 1920 the average was around 7,000,000. The selling price of picture postcards in Germany has increased from 200 to 300 per cent. over the pre-war prices, while postage, as mentioned above, has increased sixfold. The greater number of postcards being marketed in Germany to-day originate from old stocks. According to the technical bureau of the Association of Lithographers in Leipzig, there were manufactured in that city by 25 plants, large and small, during the first six months of 1913, a total of 241,308,615 picture postcards. During the first six months of 1920 these same plants produced a total of 15,838,220 cards. The 65 factories in Berlin, during the period of May to July, 1914, reported a total output of 265,000,000 cards, while during the same period for 1920 the total was only 24,000,000 cards.

These Berlin plants during the same period of 1914 employed a total of 14,800 workmen, as against 5,200 during the corresponding period for 1920—a shrinkage of almost one-third. It should be explained, furthermore, that of these 5,000 many could readily have been dispensed with, but were retained only because the Tarifamt (Wage Bureau) effected a reduction in working hours in order to avoid further increase in the number of unemployed. Until a short time ago, some 100,000 persons in Germany had derived their living from the manufacture and sale of picture postcards.

The direct effect of the depression on such an extensive industry is obvious. As an indirect effect the paper mills have suffered heavily through lessened demand for their materials—a demand which has shrunk to the minimum.

Correspondence.

"PHOTOGRAPHY NOT A MAN'S JOB."

To the Editors,

Gentlemen,—Nowadays one is accustomed to see sensational headlines in that section of the Press dealing with hair-raising matters, but I must confess that I was very much surprised to find in the sober-minded "Daily Chronicle" some rather sensational news under the above heading. Since when has photography ceased to be a man's job? It was a man's job sure enough when the old silver bath and perambulator dark rooms were the order of the day, and likewise when dry plates and the pyro-ammonia developer came along, and I was under the impression that it was still a man's job. However, the "Daily Chronicle," in dealing with the subject on Thursday and Friday of last week, leads us to believe that it is not.

As all your readers may not have seen the newspaper reports referred to, I may perhaps be permitted to make a few extracts. The notes referred to a lecture given by a woman photographer, Mdme. Yevonde, at the P.P.A. Congress, and we are told—and no doubt rightly—that it was the first occasion that a lady had addressed a gathering of professional workers, and also that no fewer than one hundred women photographers are now directing their own studios in London and the provinces!

According to the report, the lady, who is a well-known portrait photographer, said there have been famous women photographers for 50 years. The business of one, a girl of 19, in the early eighties, prospered to such an extent that in time she had 60 assistants. The photographs of another, Mrs. Cameron, were used to illustrate the first edition of Tennyson's poems. Lord Reading, sitting to Mdme. Yevonde before leaving for India, told her that he "preferred being photographed by a woman because she usually took less time than a man." And she added, in relating this incident, when she asked him which side of his face he desired to have photographed, he immediately replied, "The left." It is well known among photographers that the left is more symmetrical than the right side of the face, she remarked. Photography is, she claimed, essentially a profession for a woman. Her intuition and tact always place her at an advantage. She is quick to understand the temperament of her sitter, and she realises that it is infinitely more desirable to obtain a characteristic likeness than an artificial pose.

The above was in Thursday's issue of the paper, and on Friday the reporter returned to the subject, and we read: "Do women make the best photographers? Their male rivals admit that they do. Mdme. Yevonde, lecturing at the Photographic Fair (as reported in these columns yesterday), claimed that camera work is essentially woman's work, and a well-known man photographer told a 'Daily Chronicle' representative yesterday that he agreed with her.

"'I don't think photography is a man's job,' he said. 'I used to think so before the war, but in my absence the business was carried on entirely by women. They made such a success of it that when I came back I decided not to operate, and within the last few years I have done so only on rare occasions.' The name of this photographer is on hundreds of portraits of well-known men and women, but the actual taking of the photographs and all the subsequent processes are carried out by women."

I wonder who this "well-known man photographer" can be, and why he shirked the opportunity of having a free advertisement?

The above may be good and up-to-date journalism, but is it wise, even if true? Our ranks to-day are terribly overcrowded, and the reports quoted are likely to turn the attention of many women—who are in search of something to do and care little or nothing as to what it is—to photography, in which calling there are now too many of them, few of whom are of any real use or ornament to our man-founded profession.—Yours faithfully,

A MERE MAN.

JOURNAL OF PHOTOGRAPHY.

No. 3183. Vol. LXVIII. FRIDAY, MAY 6, 1921. Price Fourpence.

Contents.

SUMMARY

At the annual general meeting of the Professional Photographers' Association, held during the recent Congress, the proposal to make the Association an incorporated body under the Companies Acts was unanimously adopted. The title proposed for the incorporated body was "The Professional Photographers' Association of Great Britain." Subject to the approval of the Board of Trade, it was further proposed to add the words "and of Ireland." (P. 265.)

Mr. Frank Brown, ex-president of the P.P.A., makes a strong appeal for wider support of the Association. (P. 271.)

Portrait photographers are asked to take part in a forthcoming discussion on studio lighting at the Royal Photographic Society on May 24. (P. 261.)

A soft working hydroquinone developer, owing this property to addition of pheno-safranine and thereby also desensitising plates, has been worked out by Dr. Lüppo-Cramer. (P. 261.)

Mr. Walter Thomas, in the course of some notes on the Dallmeyer-Bergheim lens, emphasises the pictorial merits of this objective and the convenience in use of the later model. (P. 264.)

Mr. A. Lockett describes a simple optical device for testing the efficiency of plate backings. (P. 263.)

Camera masks for the making of passport and similar photographs in quantity are described in an article on page 268.

Progress in the speed of both lenses and emulsions prompts the thought that in emulsion making, despite the possibilities of desensitising, the problem of the future is to obtain such selective insensitiveness as will permit of the handling of plates by maker and user. (P. 262.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT

In a contributed article, Mr. R. M. Fanstone deals with some of the practical matters neglect of which is liable to affect truth of colour rendering in screen plate processes. He specially emphasises the effect of coloured objects in the near neighbourhood of the subject, also the advantage of hooding the lens, protecting the colour-filter from light and observing discretion in exposure to the safelight during development of the plate. (P. 17.)

The Prizma process of colour cinematography, recently demonstrated in London, is the first commercial success in the printing of ready-to-show cinema colour films. Its complete solution of the difficulties of colour cinematography would appear to depend upon the simultaneous making of the negative images which, as positives, have afterwards to be registered. (P. 18.)

Mr. Colin Bennett, in some recent notes in the "Kinematograph Weekly," has put the distinguishing features of additive and subtractive colour processes in a particularly clear way. (P. 19.)

At the Royal Photographic Society last Tuesday evening some most ingenious lantern diagrams for the same purpose were shown by Mr. H. S. Watkins. (P. 18.)

Some scanty particulars of a new colour process, "Triadochrome," are contained in a London local newspaper. (P. 20.)

EX CATHEDRA.

S.Q. v. M.Q. The remarkable effect of the desensitising pheno-safranine dye upon the behaviour of hydroquinone developer was referred to in the article of Mr. Raymond Crowther which appeared in our issue of April 22 last. It was there pointed out that Dr. Lüppo-Cramer has found that the pheno-safranine dye converts hydroquinone from a hard-working short-factor developer into one of long-factor, such as metol. Dr. Lüppo-Cramer has perceived the usefulness of this property in permitting the preparation of a developer similar in its properties to M.Q., although metol does not enter into its composition. A very small quantity of safranine is the new constituent of a developing formula which we may denote by S.Q. in order to mark its composition. Dr. Lüppo-Cramer has given the following formula:—

A.	Soda sulphite cryst	100 gms.
	Hydroquinone	12 gms.
	Potass bromide	1 gm
	Water	1,000 c.c.s.
B.	Potass carbonate	50 g.s.
	Pheno-safranine 1:2,000	200 c.c.s.
	Water to make	1,000 c.c.s.

The working developer is prepared by mixing equal volumes of A and B at the time of use. It is claimed for the formula that it is very similar to M.Q. in its developing properties; at the same time it is much cheaper and also permits of the development of the plates in a bright light.

* * *

Studio Technics. A meeting of the Scientific and Technical Group of the R.P.S., which has been fixed for May 24, will, it is hoped, be attended by leading portrait photographers in London. The subject is "Studio Lighting," with special reference to the distribution and efficiency of light and to the colour composition of different lights. The Group has arranged for speakers from the scientific standpoint in the persons of Mr. Leon Gaster, Mr. T. G. Priest, Mr. J. C. Elvy and others. In one respect or another, the above are entitled to speak on the subject, but we don't think any of them professes to be an expert in the use and control of light for the purposes of photographic portraiture. It will therefore be very greatly to the benefit of the subject if portrait photographers of experience will come to this meeting. They will probably learn something of the fundamentals of lighting from the scientific people, and the latter in turn will hardly escape learning something from them of the conditions of actual work. Both together, by a blend of their different kinds of knowledge, should accomplish something in the way of creating new ideas of the methods by which studio lighting may be made more efficient and brought more precisely under

control for particular effects. The artist's eye can do with help from the measurements of the scientific man, and the latter, we are confident, can benefit by being better informed of what are desiderata in the lighting of photographic studios. It need hardly be said that, without any formality, professional visitors will be welcomed at the meeting, which is held at 35, Russell Square, at 7 p.m.

* * *

Opal Pictures. It has been said that there is nothing new under the sun except that which has been forgotten, and portraits upon opal glass have been out of fashion for so long that it is possible that the present generation would regard them as a novelty. A quarter of a century ago many photographers did a fair amount of business in carbon prints upon opal, finished either in monochrome or colour and mounted in ormolu frames. These were usually supplied in addition to the original order, and formed a very remunerative side line. There was also a good sale for bromide opal enlargements in sizes from 12 x 10 to 18 x 16, the latter size fetching any price up to ten guineas. We do not know if any maker now lists bromide opal plates, but they could doubtless be obtained to order. Sepia toning was not practiced when opal bromides were the vogue, so that all sepia enlargements had then to be made in carbon, but now large sepias are as easily produced as black and white. In the smaller sizes carbon is greatly superior, and the range of colours, especially in the reds and warm sepias, is particularly attractive.

SPEED LIMITS.

In Jules Verne's book "From the Earth to the Moon" a happy description is given of the old-time rivalry between makers of big guns and makers of armour-plates. As soon as a gun capable of shattering any existing armour-plate came into being, inventors set to work to produce armour that laughed at the new monster's projectiles. This armour having been installed, only a short interval would elapse before the appearance of another and more formidable gun capable of penetrating the improved plates as if they were made of cheese. Fortunately, the emulation among lens-makers and plate-makers in the direction of attaining the highest possible speeds is on a different basis. While their efforts can hardly be said to be co-ordinated they are both striving for the common good of those for whom they cater, and the success of one does not necessarily prejudice the success of the other. At the same time it is a pertinent reflection that possessors of very rapid lenses can, as a rule, afford to ignore the introduction of ultra-rapid plates, while many will be inclined to welcome plates of extreme sensitiveness chiefly because by using them they will be spared the necessity of buying costly wide-aperture lenses.

Within limits, progress, whether competitive or not, in both these connections is heartily to be approved. Quite apart from what is mere freak photography there are several branches in which a combination of great lens-speed with great plate-speed is eminently desirable. Press photography has become part of our daily life, and for the Press photographer no lens or plate can be too rapid, provided that decent results can be obtained without adding prohibitively to the weight or bulk of the apparatus carried, or detracting prohibitively from the ease and quickness of the operations subsequent to exposure. Lenses and plates enabling high shutter speeds to be used on a winter afternoon are distinct desiderata. Instantaneous photography by artificial light can still do with further assistance from the optician and emulsion maker. Recent introductions point to the possibility that before long snapshots of scenes on the stage may be taken with ordinary theatre lighting. An attempt in that direction was made, it may be remembered, a good many years ago by Dr. Grün, who invented and put on the market a lens working, more or less inefficiently, at $f/2$. But the result was extremely poor. Indeed, in this case, it is obviously to increased plate speed rather than to increased lens speed we must look for satisfactory progress, for no picture of a stage scene taken at a larger aperture than $f/8$ is likely to be really pleasing.

The limitations of lens speed are pretty clearly defined and familiar to most photographers. Lenses of excessive rapidity have long been available for those who required them for special work. In addition to the Grün lens just mentioned an $f/2$ portrait lens was formerly made by Dallmeyer, and is still sometimes met with in secondhand catalogues. If we remember rightly it was known as the 3c, had a focal length of about 12 ins., and was intended mainly for cabinet pictures of children. Such an objective was necessarily both bulky and costly, and its popularity was therefore limited. For particular purposes, where only a very small picture was required, it was possible years ago to put together a lens working at $f/1.5$ by combining two of the old Zeiss single telepositives, which worked at $f/3$ and had a focal length of $8\frac{1}{4}$ ins. But few, we imagine, went to the length of buying two of these objectives, which cost £20 apiece, in order to produce a combination with a focal length of only a trifle over 4 ins. Nowadays there are several $f/3$ lenses on the market, other than those employed for cinematography, and one firm has in hand an anastigmat of focal lengths up to 12 ins. with an aperture of $f/2.9$. A 12-in. lens of this type has actually been made which is said to cover a half-plate satisfactorily.

It goes without saying that, while very wide apertures are extremely useful for cinematograph and other work in which only very short focal lengths are commonly needed, it is only very rarely that a lens with a focal length of over 6 ins. can be satisfactorily used at an aperture wider than, say, $f/5.6$. The depth of focus condition is a veritable rock ahead in the way of all progress in lens manufacture, as far as aperture is concerned, and on it the popularity of the $f/3$ lens among any but users of very small cameras is likely sooner or later to split. On the other hand, tiny pictures taken with a very short focus lens of this extreme rapidity will, if the lens is anastigmatically corrected, stand considerable enlargement. There is also a special sphere of usefulness for very wide aperture objectives in connection with astronomical and instantaneous colour photography.

The question whether the sensitiveness of emulsions can be increased to a much further extent with advantage to the photographic world in general is one which can be variously argued. Formerly, increased rapidity was accompanied by an appreciable coarseness of grain, and, where the quality of the negative and its capacity to stand enlargement were primary considerations, workers were inclined to shun plates of the ultra-rapid, 500 H. and D. description. But some of the modern very fast plates are of by no means objectionably coarse grain, and yield negatives of excellent quality. As new colour sensitising dyes come to be introduced—and the discovery of Pinaflavol, to which we recently drew attention, shows that progress is still being made in this branch—we may expect further advances in rapidity, apart from increase in the sensitiveness of the original emulsion. It may be thought that it is possible to have plates that are too sensitive, since no method is likely to be devised by

which they can be packed, as well as coated and cut to sizes, in total darkness. But if emulsions ten times more sensitive were to be made, our plate manufacturers would probably be equal to the task of coating them. As things are, there is no plate on the market which cannot be more or less conveniently handled, and, of course, as regards development, otherwise than in a tank, Desensitol is a valuable new friend. And it must be remembered we are only at the threshold of knowledge of imparting highly selective colour-sensitiveness to plates, and still further from what may be of importance in the future, viz., selective colour-insensitiveness.

TESTING THE EFFICIENCY OF BACKING.

Probably a majority of photographic writers assert that halation is mainly produced in the lower portion of the film, and may therefore be avoided by giving a full exposure and developing quickly with a strong solution, so that sufficient density is attained before the developer penetrates to the halated part.

This may be true with a liberally-coated plate of not too high sensitiveness and for subjects where the lights are not exceptionally bright. In all other cases, however, it can be taken for granted that oblique rays strong enough to pass through the film, and to be reflected from the back surface of the glass, will assuredly make their way to the front of the film again, and must inevitably be capable of development. That, indeed, is corroborated by the well-known fact that halation may often be reduced by rubbing the negative with a pad of chamois leather moistened with methylated spirit. If halation were really confined to the lower part of the film friction would have no effect, unless one rubbed almost through the gelatine.

The reason why halation becomes more manifest with under-exposure and forced development is simply because of the greater contrast in the lights and the inadequate shadow detail. Halation would be quite as evident in a fully-exposed negative of the same subject, were it not that by stopping development sooner the result is softer, while the fuller detail in the shadows cancels part of the defect, or, rather, withdraws attention from it. Moreover, with incomplete light-action in the shadows, there is always a tendency for the outline of bright portions to spread sideways; and this is quite independent of halation by reflection, since it may be seen in bad examples of under-exposure even when the emulsion is coated on an opaque or non-actinic support.

Soft development generally has a wonderful effect in cases where halation is feared. Hence we see admirable results obtained from difficult subjects, both by means of over-exposure, followed by development for a short period only with a strong normal solution, and by the widely-different method of over-exposing and developing for a long time in a tank with a dilute solution almost devoid of alkali. The second way must clearly allow penetration and extended action of the developer right through the film, yet it succeeds after a fashion, for the same reason as the first, namely, that both tend to reduce contrast while bringing out detail in the shadows.

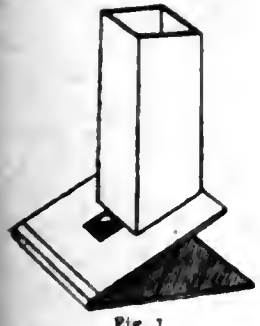

Fig. 1.

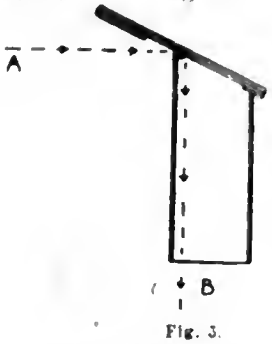

Fig. 3.

I suggested twenty years ago ("B.J." Supplement, November 1, 1901) that the probability or otherwise of halation occurring with any given plate or backing might be tested merely by visual inspection. Recently I have contrived an improved apparatus for the purpose, which is shown complete in Fig. 1. Two rectangular pieces of thick blackened cardboard, 4¼ in. by 3¼ in., are cut. On one of these, a couple of parallel lines are drawn across the middle, 3/16 in. apart, as at A and B in Fig. 2, and against these lines two apertures are marked and cut out, as at C and D, one being ¾ in. square and the other 1½ in. square. Between the two central lines is glued a narrow strip of black velvet E, indicated by shading. The second card only needs to be covered all over with black velvet on what will be the inner side.

A 1½-in. square blackened cardboard tube is next made,

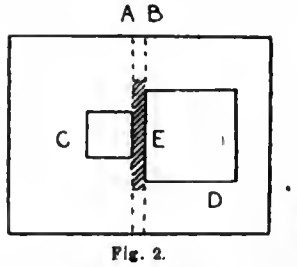

Fig. 2.

4¼ in. long at the longest side, and having its bottom cut across at an angle of 45 degrees. This tube is glued over the larger opening in the first card, having turned the latter so that the velvet strip is underneath. Slips of opaque paper are then pasted round at the junction to stop up any possible crack. The two cards are lastly hinged together with a strip of opaque tape or cloth, leaving just sufficient gap for the insertion of a plate of average thickness.

To use the apparatus the plate to be tested, or a portion cut from it if large, is laid film upwards on the velvet of the lower card, the upper card being then pressed down on the plate in close contact. The small opening is pointed obliquely at a brilliant light, preferably direct sunshine, while the observer looks straight down the tube. Fig. 3 is a sectional plan, in which the arrows show the general course of the light coming from the direction A, the eye being placed at B.

There will be seen, on an unbacked plate, a bright patch or streak, formed by rays that have passed through the film under the small opening, and have been reflected back by the rear surface of the glass, emerging again through the film near the edge of the large aperture. On placing an unbacked plate with its glass side to the opening the halation is greatly increased, which quite accords with theory. A thickly-coated plate is visibly less penetrable than a thinly-coated one, while celluloid film, contrary to general belief, unmistakably shows reflection, though decidedly less than plates.

In every instance, however, when a really effective backing is applied no rays are returned, and only blackness is seen in the tube. In the case of an anti-halation plate with a non-actinic substratum between glass and emulsion the result is equally satisfactory, since the only light that penetrates or can return is non-actinic.

The foregoing simple apparatus gives a real test of halation proper, and it will be found that actual exposures in the

camera agree well with its indications, though plates of different speeds will, as might be expected, vary somewhat in the amount of halation capable of development. It may be stated, in conclusion, that, with a bright enough light-source, it is quite practicable to interpose a filter before the admission aperture of the tester, in order that the trial may, if desired, be limited to rays of a particular colour.

A. LOCKETT.

THE NEW BERGHEIM LENS.

In 1896 a sensation was created among pictorial photographers by some pictures exhibited at the Royal Photographic Society's exhibition in Pall Mall, for nothing quite of the kind had been seen before.

In place of critically sharp definition, which had hitherto reigned supreme, the photographs exhibited were deliberate attempts to produce softened outline *without destroying structure*. So effectively was the object achieved that for a time these were accepted, except among more advanced photographers, merely as examples of some crazy worker's efforts, yet they were the forerunners of what is quite commonplace to-day. Indeed, for the express purpose of producing a similar type of results, quite a number of makers now issue special lenses for giving more or less diffused definition, quite another matter from attempting to gain the same end by means of highly corrected lenses racked out of focus, and producing more pleasing results.

In this country, for some reason, these soft focus effects did not gain much favour; indeed, when American pictorialists first sent over to England a collection of their works, which were exhibited at the Royal Photographic Society's house in Russell Square, they were openly laughed at by most photographers as being merely freak works by a pack of mad Americans Yet to-day they would likely enough seem old-fashioned, were it possible to view them again collectively.

Thus it always seems with any attempt to break away sharply from any conventions; first scoffing, then silent toleration, and in due time acceptance, assuming the innovation to contain elements of truth. It certainly has been so in this instance of soft focus work in pictorial photography.

So far as I know, the first deliberate attempt to produce a lens adapted for this special purpose was that known as the "Bergheim," introduced by Messrs. Dallmeyer from particulars supplied by Mr. Bergheim, in those days equally well known as a painter artist and as a pictorial photographer. The late Mr. T. R. Dallmeyer, in a lecture on March 6, 1896, brought this new power—for so the lens proved itself—before a crowded meeting at the London Camera Club, the late Earl of Crawford being in the chair. It was a memorable meeting, from which world-wide results have spread.

Mr. Dallmeyer described Mr. Bergheim's ideas and aims, how his firm had carried them out, the construction of the lens, and some of the advantages claimed on its behalf.

(1) It was of the telephoto type, of variable focal length, and needed comparatively short camera extension.

(2) It worked with absence of distortion.

(3) It allowed suppression of critical sharpness in varying degrees *without destruction of structure*.

(4) It gave more uniformity of definition and better rendering of different planes in a subject by keeping them within the range of useful focus instead of one plane being sharp and all the rest out of focus.

(5) It produced painter-like effects.

Obviously, any means which could place such advantages within the power of photographers marked an important advance, and so it has proved, for here is an instrument of great plasticity in that it gives power to treat subjects with greater freedom than had been possible before its introduction.

It is an artist's lens for artistic photography; a means for thoughtful expression rather than haphazard snapshot work. Whilst simplicity itself in handling, it needs understanding, which perhaps explains to some extent why it has not been more widely used in the past, but now that bitingly sharp definition, especially in the better type of portraiture, has ceased to be the beau ideal, we may see this lens come into its own, especially as recently some important improvements have been made in its construction, notably reduction in size and weight, the No. 1, with a range of focus from 12 inches to 25 inches, measuring only 4½ inches in length, diameter 2½ inches, and weighing but a few ounces.

Just think what it means, having one lens and being able, simply by a twist of the lens tube, instantly to change it from a 12-inch, into either a 15-, 18-, or 25-inch lens, or, if desired, to stop at any intermediate stage in the focal length. Also, what a change in size of image is possible by this means, *without moving the camera or sitter;* no having to bring them close together to obtain a large head, with its consequent distortion of features, and hands out of all proportion to the face, for with this lens true drawing is obtainable even when a large head is photographed on a comparatively small plate.

Then varying degrees of diffusion are obtainable at will, always with structure truthfully rendered, planes better differentiated; indeed, it more nearly approaches painting with light than any other means I know of, and is such a joy to use when once its simple principle has been mastered, not a matter of any real difficulty. It only needs a slight turn of the focussing screw in order to make the necessary correction between visual and chemical foci. In practice, this is done by first focussing in the ordinary way, first getting the image as sharp as possible on the ground glass, and then racking the camera in slightly, 1-60th of whatever focal length you are using the lens at; that is all there is to do to ensure full correction, so that when exposure is made the lens is working at its chemical focus in place of visual, exactly as is done with uncorrected lenses of the so-called spectacle lens type at one time so popular among photographers.

In practice, even the above simple calculation need not be made, for in portrait work, if the eyes be focussed upon the point of sharpest definition, a slight racking-in of the lens until the point of focus has been transferred to the ear of the sitter will give a negative which, after exposure and development, will be found to have correctly rendered such definition as was desired, and placed exactly as intended. The slight alteration of point of focus from eye to ear is sufficient to make all necessary allowance for difference between visual and chemical foci. From the description it may appear rather a complicated business: in practice it is simplicity itself; just a turn of the focussing screw to throw the point of focus slightly back, and the matter is ended.

Not every photographer cares for extreme softness in definition, but to those who prefer their subjects modelled and outlined with such degree of sharpness as they see in nature this Bergheim lens will prove a treasure, offering, in the one instrument, a wonderfully wide range of possibilities, and these notes may end with the observation that one of the original form—a No. 1 of 12-inch or 25-inch focus—has been for many years one of my favourite lenses, and was only superseded quite recently by one of the improved new form now available of considerably reduced size and weight, a matter of some importance in outdoor work when carrying a large camera, stand and several lenses, when the fire and energy of youth is sobering down before the approach of that period of life when physical effort loses some of its charm.

W. THOMAS.

THE P.P.A. CONGRESS.

THE ANNUAL GENERAL MEETING.

The annual general meeting of the Professional Photographers' Association was held in the Congress Room of the Horticultural Hall on Friday, April 22. Mr. Frank Brown (President) was in the chair.

It was agreed unanimously, on the proposition of Mr. Swan Watson, seconded by Mr. Speaight, to take the minutes of the last meeting as read.

The President said that the first business was the consideration of the annual report of Council and balance-sheet. It was usual for the President to make some fairly exhaustive remarks on such an occasion, but he would only draw attention to the significant progress of the Association in respect to membership. In 1916 the members numbered 720, and in 1920—after an interval of only four years—they numbered 1,073. (Applause.) This figure, however, was not enough, considering the importance of the Association, and the tasks it had to face in the comparatively near future. During the next twelve months some very serious work would have to be done, and he knew that the Council, on behalf of the members, was "prepared to take its coat off."

Mr. S. H. Greenway moved the adoption of the annual report, and congratulated the President and Council on the generally satisfactory state of affairs.

The President asked for any criticisms.

Mr. A. Barratt said that he thought members generally would be pleased with the way the Council had looked after the interests of the Association. There was one point which occurred to him. It would be a very desirable thing, if it was possible to arrange, for the present exhibition of professional work to be transferred subsequently to Edinburgh and Manchester. That was a thing to be undertaken, not by the Council, but by the provincial members. Then there was the question of the "Circular." One of the difficulties he saw ahead was the lack of interest taken by members as contributors. That was one of the reasons why the "Circular" was not as interesting as it should be. The reports of Council meetings were, by the time they appeared in the "Circular," somewhat out of date, and superfluous also, because members had already read the reports in the "British Journal." He suggested that underneath the reports of Council meetings in the "British Journal" there might be, by arrangement with the Editor, an advertisement inviting non-members to become members. A few months ago he read in the "Circular" that a photographer made application to the Council on the matter of getting a reduction on his electric light bill, and after the help had been given it was found that he was not a member of the Association. The moral seemed to be, When in trouble come to the Association, but the use of its machinery should only be available for those who had become members. There was another matter. Would it not be possible to form a small committee for publicity purposes? They had had a demonstration within the last few days, in connection with the exhibition, of the value of Press publicity, and much good had been done by the excellent Press reports of Madame Yevonde's lecture. That was all to the good so far as the Association was concerned, and there should be more of it, done officially by the Council. He would suggest that next year a lecture be given by some advertising expert on the question of advertising or publicity, and how it affects photography. Then—to bring up another matter—was it not possible for the Council to get out a graded minimum price list? Such a thing would be very useful both for town and country members, to enable them to see what prices were being charged in general, for it would be a great pity if ever they allowed prices to come down to the standard of pre-war days. (Hear, hear.) Another suggestion for the next Congress: could not the President and Secretary of the French Association of Professional Photographers be invited to attend? Some friends from abroad had been with them on the present occasion, and this international visiting was all to the good. (Applause.)

The Secretary said that with reference to Mr. Barratt's remark about the "Circular," the report of a Council meeting in the "Circular" was much fuller than the report in the "British Journal," although, of course, neither report gave a complete account of the Council's proceedings, since there were some things which it was expedient to withhold from publication, at least for the time.

Mr. Coles suggested that if they were not satisfied with the "Circular" some of the blame must fall upon non-contributing members, who had failed to make the most of this medium. He himself had been intending to write, but had put it off until now. And he had not noticed contributions from Mr. Barratt.

Mr. Barratt, however, pointed out that he had contributed.

The motion to adopt the annual report of Council was then put, and carried unanimously.

Mr. R. N. Speaight, in moving the adoption of the balance-sheet, said that in these times when one could hardly look at a financial column without finding depression it was a great pleasure to him to present a balance-sheet which was so very satisfactory. The Association had no liabilities, except one, which it could not help, the liability, namely, in respect to those members who had paid their subscriptions in advance. During the year they had spent £698 5s. 1d., which was quite a large sum for an Association of that size, but they had received £830 9s. 10d. in revenue from subscriptions and interest on investments and other odd receipts, so that their accumulated funds were £132 1s. 9d. larger than they were a year ago. (Applause.) The Association's assets were not fictitious. They included £500 in 5 per cent. War Loan, £100 in 5 per cent. National War Bonds, £300 on deposit at the bank, and £90 on current account. The expenses had been heavier than in the previous year; the amount paid for secretarial work was £150 more—to mention only one item—so that it was extremely satisfactory to see an extra £132 added to the reserve. It was a genuine reserve at the moment of close on £1,000. The subscriptions had increased in number by 168, and in amount by £115 over the previous year. Everything the Association had touched it had made on. There was a profit on last year's Congress, yet no one could say that those who attended did not get their money's worth on that occasion. The balance to the good on the Congress account was £13. He hoped that as much, if not more, would be made this year. It was the Council's duty to see that in all its enterprises the Association came out on the right side. (Applause.)

The adoption of the balance-sheet was moved formally by Mr. W. J. Stocks, and seconded by Mr. H. J. Jarman, the seconder saying that he thought the thanks of the members were due to the Treasurer (Mr. Speaight) for his masterly handling of the accounts, for he supposed that the major part of the duty fell to him.

Mr. George Hana said that he would like to protest against this balance-sheet. The Association was accumulating far too much money, and it ought to be spent in propaganda and general usefulness. Some hustle should be put into the Finance Committee, so that they made fuller use of the funds they possessed.

The President said that Mr. Hana was quite aware that some suggested steps were being taken with regard to propaganda, but the matter Mr. Hana had raised would not be allowed to slip.

The balance-sheet was then adopted unanimously.

Mr. Speaight, in reply to Mr. Hana, said that there had been a big scheme in contemplation, which had the support

of the Finance Committee, but three weeks previously he as treasurer had asked that a resolution which committed them to considerable expenditure might be rescinded, and the matter be postponed until the labour troubles had passed over their heads. It would be well to wait and see how things went before allowing money to go out of the bank on fresh enterprises, however excellent they might be. The success of the balance-sheet was only in small part due to any efforts of his own. In greater part it was due to the late Secretary and Treasurer, Mr. S. H. Fry. (Applause.)

A telegram from Mr. Fry was read at this point, regretting inability to be present, owing to a bad influenza cold. It was agreed to communicate to Mr. Fry an expression of regret at his absence and its cause, and to offer him the best wishes of his fellow-members.

The Secretary said that he had a letter from Mr. Rigden, one of the auditors, who informed him that he was now going out of business, and would no longer be a member of the Association.

Mr. Alfred Ellis then proposed the motion relating to the incorporation of the Association. The motion ran as follows:—

"That having regard to the disadvantages of the present constitution of the Association and with a view to it becoming a formal legal entity possessing legal rights, and with a view to the effective protection and indemnity of its officers and removing impediments to its progress and acquiring greater certainty in regard to its correct administration, government and powers, it is resolved that the Council be authorised, at the expense of the Association, to register under the Companies Acts, 1908 and 1917, a new Association, not for profit and limited by guarantee, to be called the Professional Photographers' Association of Great Britain (Incorporated), and that by the constitution of such new Association the liability of members shall be limited to

"(*a*) A subscription of 10s. per annum, and

"(*b*) *A contribution to the assets of the new Association in the event of the same being wound up during the period of membership of each member or within one year afterwards* for payment of the debts and liabilities of the Association contracted before the time at which such member ceases his membership, and of the costs, charges and expenses of winding up the same and for the adjustment of the rights of the contributories among themselves, such amount as may be required *not exceeding* 10*s. per member.*

"And that all the members of the existing Association shall be entitled to become members of such new Association when registered without payment of any further subscription until the expiration of the period for which their respective subscriptions have been paid to the present Association, and that upon the registration of the new Association the assets of the existing Professional Photographers' Association be transferred to such new Association.

"And that a committee be elected from the Council of the existing Professional Photographers' Association of Great Britain with power to settle the Memorandum and Articles of Association embodying so far as practicable the objects and rules of the existing Association and such further objects and rules as such committee may be advised are desirable."

Mr. Ellis said that the question of incorporation had been before the Council for a considerable time past. Mr. W. Illingworth read a paper on the subject in 1919, and since then the subject had received a large amount of attention from the Council, and the Council was unanimous in recommending the resolution to the members. The Association as at present constituted had no legal entity, and the officers, Council, and, in some degree, the members were liable for its debts and liabilities. As their first secretary, he, in conjunction with Mr. A. Mackie, framed the first rules and regulations of the society, and also any amendments since then. He thought it would be agreed that these had answered their purpose very well while the Association was a small one, but the Council was of opinion, now that the membership was over a thousand, and there were invested funds, that the Association should be placed on a firm and legal basis. The present rules did not provide for many contingencies which might arise, and therefore the rules should be legally drafted in accordance with the Companies Acts, and should properly define the duties of president, secretary, treasurer, chairman, council and trustees, so that those who carried on the work of the Association might be properly protected from legal liability. At present outsiders did not recognise the Association itself, but looked to the secretary or the individual councillor as the responsible person for any liability incurred, whereas under incorporation these officers would be acting as agents of the Association. Incorporation not only insured the safety of the officers, but it protected the members, for in the event of the Association getting into debt or being "wound up," the most that each member could be called upon to pay was 10s. in addition to his annual subscription. The funds of the Association would be better protected. At present there was no restriction as to their use by a majority of the Council. They could divide the funds among existing members or spend them on absurd schemes. If they became incorporated, the Board of Trade, when reviewing the articles of association, would provide that the funds be only used for stated objects and purposes that would be considered beneficial to the Association generally, and the Council would not be able to make any alteration or deviation from the articles of association without the further approval and permission of the Board of Trade on each occasion. The Secretary informed him that since the notice of motion was sent out he had received two suggested amendments, one from an Irishman that the word "Ireland" should be added to "Great Britain" in the title, the other that the title should be "The Institute of Professional Photographers." If they thought seriously of these alterations he would suggest that they be proposed as two amendments, after his proposition had been seconded by Mr. W. Illingworth, who was very much interested in the scheme. Mr. Vaughan, the hon. solicitor, was in attendance, and would be pleased to answer any legal questions on the subject of incorporation (Applause.)

Mr. W. Illingworth seconded the motion. After he was first elected on the Council he quickly came to the conclusion from his observations at its meetings that they were on the wrong track, and had not a leg to stand on, if they were to attain the object for which the Association was founded—namely, the improvement of the status of those practising photography as a profession. He did not mention his thoughts, but he definitely made up his mind that he would bring a motion forward at the proper time, a motion which, if acted on, would place the Association on a sound business foundation. That time did arrive, and the motion was now before the members. It was very gratifying to him to know that his colleagues on the Council had recognised the force of the arguments he put before them at one of the meetings during 1919, when he urged that the incorporation of the Association was a sound and practical business proposition, and was absolutely imperative to the carrying out of their fundamental objects. This recognition by his brother councillors had not been obtained without persistent determination on his part, and nothing could have given him greater satisfaction than to realise that they had seen the wisdom of acting on these ideas. He seconded the proposal as indisputably the most sound and practical business proposition ever put before that society of professional photographers, and asked that it might be supported unanimously.

Some discussion then took place on the order of the proceedings, the President and Council not having yet been elected.

In reply to questions from Mr. Barratt, Mr. Greenway, Mr. Swan Watson, and others,

Mr. Vaughan (the hon. solicitor) said that undoubtedly when once the Association became an incorporated body the members would have to re-elect their president and council, and the only reason why he had suggested taking that business

later, after this resolution had been decided, was that another resolution might be put forward stating definitely that the president and council now to be elected should be president and council for the new association. The Companies Acts provided that the election of council—which took the place in this instance of what was usually called a board of directors—should be effected by members of the incorporated body after incorporation.

Mr. Barratt said that he believed a general meeting must be called in any case to confirm what had been done.

Mr. Vaughan said that this was so; there must be a confirming meeting after the registration of the company.

The President, in reply to a member who asked whether this suggested scheme had the unanimous support and approval of the members of the Council, said that after two years' careful deliberation and consideration, it had received the unanimous approval of the entire Council.

It was agreed eventually that the election of president and council should be proceeded with before the resolution with regard to the proposed incorporation was put to the meeting.

Mr. Alfred Ellis said that according to the present rules, as a Professional Photographers' Association, the Council had to nominate a president, treasurer, and twenty-four members of council, twelve of whom should be London, and twelve country members, and if there were any other nominations from members of the Association a ballot had to take place. On this occasion there were no other nominations, and therefore the names went forward without the necessity for a ballot.

Mr. Greenway protested against this procedure. The outgoing Council might nominate, but this did not necessarily mean election. He wanted to show that the feeling of the meeting was in favour of the gentlemen proposed for election, whatever might be the fate of the resolution with regard to incorporation. It seemed to him that the new procedure not having yet been settled, this important business must be done according to the old procedure.

The President, signifying his willingness to take the resolution at this point,

Mr. Greenway formally proposed, and Mr. Jarman seconded, the election of the following members who had been duly nominated to serve as officers for the ensuing year:—

President, A. Swan Watson.

Past President, Frank Brown.

Hon. Treasurer, Richard N. Speaight.

Members of Council.

London.	Country.
Adams, Marcus, F.R.P.S.	Chaplin, W. B. (Windsor).
Bassil, Angus.	Chapman, A. H. Ll. (Swansea).
Bennett, Arthur.	Chase, Gordon (Bromley).
Corbett, Alexander.	Chidley, T. (Chester).
Dickinson, C. F.	Fry, S. Herbert (Ripley).
Ellis, Alfred.	Illingworth, W. (Northampton).
Gray, W. E., F.R.P.S.	Lambert, Herbert (Bath).
Haines, Reginald.	Read, F. (Southport).
Hana, George.	Spink, H. C. (Brighton).
Speaight, Richard N.	Turner, T. C. (Hull).
St. George, H. A.	Wedlake, W. H. O. (Forest Gate).
Wakefield, F. G.	Wheeler, Halksworth (Folkestone).

Secretary, Lang Sims, 437, Brixton Road, London, S.W.9.

The motion was carried unanimously amid applause.

The discussion on the main resolution was then resumed.

Mr. Vaughan (hon. solicitor), in outlining the advantages of incorporation, congratulated the Association on the step it was now proposing to take. As the Association stood to-day it was really a non-legal body. While every one of its officers could be "shot at," the society as a society could get no redress for any wrongs it suffered. On reading the rules of the Association as at present in force it was very difficult to say what were the powers and the limitations of the officers and governing Council. Incorporation would place all on an absolutely firm footing. The Association would be like a company in many respects, and the Council would be in exactly the same position as the board of directors of a trading concern. The members' voting powers would all be defined by the memorandum and articles of association, which would be drawn up in accordance with the Companies Acts. Before incorporation, the memorandum and articles would have to be submitted in draft to the Board of Trade. The Association was not to be registered for the purpose of making a profit, but for the good of a certain body of persons—namely, professional photographers—and in that memorandum and articles the objects which the Association might carry out would be defined. That was the limitation which was put upon the powers of the executive, for these objects could not be extended without a special resolution which had afterwards to be approved by the Board of Trade. Care would, of course, be taken that the objects were sufficiently wide to enable the Association to carry on its work with reasonable freedom. It might be necessary to enlarge them in some respects. The subject of propaganda had been referred to at that meeting, and also an improvement of the quarterly journal. The object clauses must be sufficiently wide to enable the executive to give effect to these objects if considered desirable. If the usefulness of the Association was to be extended it would necessarily mean that certain risks were incurred, more expenditure would be called for, and contracts might have to be entered into with advertisers and manufacturers. It was desirable that the executive should have power to undertake this, and that their liabilities should be protected. There might, for instance, be some slip made with regard to a certain firm or individual, and it was desirable that the liability of particular officers should be effectively safeguarded. In working, the plan would prove by no means complicated. In any matter of difficulty it would only be necessary to refer to the memorandum and articles, and doubts could be set at rest immediately. The memorandum and articles were the result of very careful thought by people who had had to frame and constitute associations of that character before. It would mean to the executive greater certainty both as to powers and rights. With regard to assets, at present these had to be held by an individual; in future they would be no longer in the name of any individual, and the banking account would be in the Association's name and could only be touched by persons authorised by the council, which might at any moment revoke its authority. Supposing a bank were to fail the Association, as a body, at present would have no rights against the assets available. By incorporation the Association would save itself from many equivocal positions.

Mr. R. Haines asked whether, supposing the resolution were passed, the title of the Association could be altered afterwards.

Mr. Vaughan said that that would have to be done by a special resolution which would require the sanction of the Board of Trade. The Board of Trade, however, would not be captious in such matters, as long as no confusion with any body was created.

The President said that the title "Institute of Photographers" was suggested. The word "professional" surely should be inserted.

Mr. Ellis said that they would only be following the example of architects or engineers, who did not use the word "professional."

In the course of further discussion, however, it was pointed out that there were no amateur architects, engineers or auctioneers.

The President said that this proposed amendment would seem to make the Association include all photographers, whereas this had been an association of master photographers.

Other expressions of disapproval at such change of name were made, and the amendment which had been sent in was withdrawn.

Mr. Vaughan stated, in answer to a question, that it was necessary to include the amount of the subscription in the resolution because the Companies Acts required that the liabilities of the members must be stated, but if an alteration was desired later there would be no difficulty.

On the motion of Mr. A. Barratt, it was agreed, with two dissentients, that the words "and Ireland" should be added to the title.

Mr. Vaughan advised that the words "if permitted by the Board of Trade" should be added in this amendment, because as they would be incorporated under an English Act of Parliament some objection might be raised, though he hardly thought it likely.

This was agreed to.

The original resolution, with this addition of "and Ireland" to the title, was then put and carried with absolute unanimity and amid applause.

The President congratulated Mr. Illingworth upon his successful endeavours.

A vote of thanks was accorded to the hon. solicitor for his attendance, and the business then concluded.

PHOTOGRAPHS FOR PASSPORTS.

In the early days of the war I had to produce quickly thousands of small portraits to be used on Government permits.

Happily these days are gone, but the photo-permit seems to be a legacy of the war, and almost any day now an emergency might arise where a small photographer would find a big volume of business offered to him. My experience and method of working may therefore prove instructive.

It was left to me at a price per head to take the men anywhere I liked, to produce two stamp-size pictures, and to get the work through in a few days. At first I took them in the studio, using a Billcliff repeating back, but I soon found that I could never cope with a percentage of the men that way, and that I would ruin my ordinary trade. So, after thinking the matter out, I decided to take them in batches at the docks, railways, or sheds where they were employed. I used my half-plate outfit, which has six double dark slides. Eighteen on a half-plate was what I produced, and I took six at a time on a third of the plate. To cover up the other two-thirds during exposure was simple, two shapes of thin, dark card being necessary, one

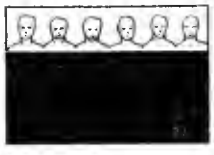

Fig. 1.

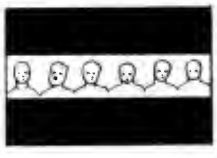

Fig. 2.

always being in position immediately in front of the focussing screen or dark slide. The illustrations will show how this works (figs. 1 and 2).

Now, the only thing I had to be careful of was to avoid duplicating exposures. I made a blunder the first day, but never again, for after that I always carried a note-book with skeleton drawings of the twelve plates, crossing off each portion as exposed. Well, then, six men were placed against a wall, shoulder to shoulder, the exposure made, and so *ad infinitum*. To avoid changing the focus frequently, I worked through the top portions of plates first, and so on. It will be seen that I made 216 portraits on 12 plates without changing. I never risked wholesale disaster by having an assistant, and the way the "sitters" fell into the spirit of the thing was wonderful, arranging themselves in groups of approximate heights, so that I had scarcely ever to leave the camera. My day's operating—frequently finishing after the dinner hour—usually was about four changes, or 864 faces on 48 half-plates. To develop those, dry off, and make two glossy bromides from each before the next morning was not a tremendous task, and at the charge of 1s. per head shows a return of over £40!

Sometimes I had to number them. This was done by pinning a numbered "cloak-room" ticket on one of the subjects. I never cut the prints up, as I found the clerks and foremen who handled them could do that better when allocating the lots to the different departments.

In finishing up my contracts, particularly with railway men, I had to pick up a few at a time at different points. I took those singly, working eight on a plate, as follows (figs. 3 and 4):—

It will be noticed that here again two intermediates of dark card allow for all the different changes, merely by turning them about and upside down.

This way of producing "Victoria" midgets is useful for fêtes or similar outdoor gatherings, as a repeating back is not quite suitable for a field camera.

Passport or permit photographs may mean a good help to the studio business. In Ireland, at present, every owner or driver of

Fig. 3.

Fig. 4.

a car or motor-cycle must have a properly authorised permit, with photograph affixed.

Do not make the mistake of charging too small a price for this work. "Oh! any sort of thing will do," we are told. "Yes," I reply, "but I have to upset all my routine to give you quick service, and that is what we charge you for."

You may frequently bag a local big-wig, who ordinarily dislikes being photographed. In such case, do not make the fatal mistake of making him wait while you take two or three large negatives of him. The clever way is to take, without any apparent fuss, but, of course, as carefully as possible, one large negative only. As the sitting is "only for a passport," you ought easily to cajole a good expression. Then copy the small prints from this negative. A week or ten days later you may send for approval the "enlargement," with every chance of a good order accruing. J. Effel.

Exhibitions.

HAMMERSMITH PHOTOGRAPHIC SOCIETY.

The exhibition which once again has been brought together at Hampshire House, Hog Lane, Hammersmith, represents very well the present-day standard of pictorial work in landscape and portrait photography. Quite a respectable proportion of the work comes up to the standard of the larger exhibition and there are very few foolish things. The work of Louis J. Steele, always fresh in his outlook, is here represented by some very pleasant examples, and other notable exhibitors of both portraiture and landscape are Charles R. Wormald and Hugo Van Wadenoyen. In portraiture, the prints by Marcus Adams add distinction to the walls; and, in landscape, F. Prior has some imposing prints, rather theatrical in style, but giving promise of more mature achievements. The members' section represents a large volume of enthusiastic effort, and contains the makings of a number of fine works. There is a collection of colour transparencies which can be seen after dusk by artificial illumination. The exhibition remains open until May 19 next, and may be visited without charge for admission.

FORTHCOMING EXHIBITIONS.

April 21 to May 19.—Hammersmith, Hampshire House, Photographic Society. Particulars from the Hon. Secretary, C. E. Altrop, 14, Southwold Mansions, Widley Road, Maida Vale, London, W.9.

April 27 to May 25.—Bury Y.M.C.A. Photographic Society. Particulars from the Hon. Secretary, A. Benson Ray, 8, Agur Street, Bury, Lancs.

April 28 to 30.—Nottingham and Notts. Photographic Society. Particulars from the Hon. Secretary, A. Beeston, 103, Nottingham Road, Nottingham.

August 27 to September 10.—Toronto Camera Club. Latest date for entries July 30. Particulars from the Hon. Secretary, J. R. Lawson, 2, Gould Street, Toronto, Canada.

New Books.

Photographic Abstracts. London: Royal Photographic Society. 10s. per annum.

THE first number of this systematic review of the technical photographic press and of periodicals relating to branches of science connected with photography has at length appeared under the direction of Mr. E. K. Hunter, Dr. T. Slater Price, Mr. F. F. Renwick and Mr. B. V. Storr, assisted by a staff of abstractors. The arrangement of the abstracts into eleven groups is one which, we think, will allow of subject-matter being found without much difficulty, and without the need of cross-references, a device which apparently the compilers propose to dispense with altogether, since no instance of it is to be found in this first number. Nevertheless, we think further experience will show that occasions arise when a limited amount of cross-referencing adds to the usefulness of the publication without materially increasing its length. The sections into which the abstracts are classified are as follows:—

Colour Photography.
Cinematography.
Manufacture of Photographic Materials.
Photographic Appliances (Cameras, etc.).
Photographic Optics.
Photo-Mechanical Processes
Radiography.
Applications of Photography (Astronomy, Spectroscopy, Photo-micrography, etc.).
Sensitometry, Actinometry, Photometry.
Theory of Photography.
Photographic Processes.

It will be seen that the methods of what is usually termed "practical photography" form only one of the eleven sections: the purpose of the publication, which alone could justify its appearance, is the wide scope of its review among subject-matter, and over periodicals which are less directly related to the technics of photography than are the papers and articles published in purely photographic journals. By keeping this aim clearly before them, the publication committee will render a most valuable service to students of photography now and in the future. They have made an excellent beginning on these lines under conditions which, as they say in a brief prefatory note, have not been favourable to creating the full organisation necessary for putting their ideals into effect. "Photographic Abstracts" is sent free to members of the Scientific and Technical Group of the Royal Photographic Society; by others it is obtainable, price 2s. 6d. per copy, or 10s per annum, from the R.P.S., 35 Russell Square, London, W.C.

New Materials.

Super-Gladiator Plates. Made by the Mawson Co., Ltd., 81, Northumberland Street, Newcastle-on-Tyne.

THE MAWSON CO. have applied the prefix "Super" to their Gladiator plate in significance of recent improvements in the emulsion which have greatly increased the rapidity. The Gladiator plate, within our experience, has always been one of extreme speed, and it is evident that by further experiment in its manufacture this quality has been enhanced. The makers now rate it at 500 to 530 H. and D., and claim that it is the most rapid emulsion upon the market. It would require a more extensive series of tests than, we think, we can be expected to make to examine the practical performance of the plate in comparison with others; and, indeed, from the variety of conditions under which a plate is used, within and outside the straight-line portion of the characteristic curve, it can hardly be maintained that a plate is of the same practical speed for different descriptions of work—at any rate where the margin of difference is not a very wide one. But it certainly can be said that the Super-Gladiator is a plate of the most extreme speed and, moreover, one which develops readily and easily gives negatives of any required degree of vigour. And it works exceedingly cleanly, yielding a negative of remarkable fineness of grain for an emulsion of such rapidity. As the oldest makers of dry plates in this country the Mawson Co. have certainly reason to congratulate themselves upon their latest success in achieving a new record in emulsion speed.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MAY 9.

Bowes Park and Dist. Phot. Soc. "Carbon Printing." F. P. Bayne.
Cripplegate Photographic Society. Demonstration. B. C. Wickison.

TUESDAY, MAY 10.

R.P.S. "The Theory of the Screen in Half-tone Work." L. P. Clerc. "Suggestions for a New Printing Process." K. C. D. Hickman, B.Sc., A.I.C. "The Behaviour of the Silver Bromide Particles in Dry Plates towards light, alpha and beta rays." Prof. The Svedberg of Upsala.
Hackney Phot. Soc. Print and Slide Competition; Seascape.
Manchester Am. P.S. "Bromoil Demonstration." S. Grimshaw.
Portsmouth Camera Club. "Photography—Its Present-day Importance and Power." Messrs. Johnson and Sons.

WEDNESDAY, MAY 11.

Croydon Camera Club. "Shaw, Shakespeare and Cæsar." Cavendish Morton.
Photo-micrographic Soc. Annual General Meeting, Exhibition, etc.

THURSDAY, MAY 12.

Gateshead and District Camera Club. Annual Meeting.
Hammersmith (Hampshire House) Photographic Society. "Improving the Negative." R. H. Lawton.
Kinning Park Co-op. Soc. C.C. Open Night.
Kryn and Lahy (Letchworth) Phot., etc., Soc. "The Romantic in Landscape."

SATURDAY, MAY 14.

Glasgow and W. of Scot. Amateur P.A. Excursion to Bothwell Castle.
Hammersmith (Hampshire House) Phot. Soc. Outing to Lewes (three days).
Kinning Park Co-op. Soc. C.C. Outing, Bishopton to Erskine Ferry.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, May 3, Dr. Rodman in the chair, when Mr. H. S. Watkins read a paper on "Principles of Colour Processes." Owing to pressure on space a brief report will be found on another page of the "Colour Photography" Supplement.

CROYDON CAMERA CLUB

THE club rooms last week closely resembled an American bar prior to the Reformation, Mr. J. W. Purkis being the cocktail mixer for the evening. The simple subject chosen was "The Principles Underlying Photographic Printing," simple only in the sense that he made it so. For an instructive series of elementary articles the lecture-demonstration would make an admirable basis; it was essentially one unsuitable for a brief report. Nearly every familiar printing process, from P.O.P. to Carbro, was reviewed, and the many telling experiments kept interest alive to the end.

So interested was the artistic, but not too scientific Mr. Harpur, that in the discussion he expressed himself as completely and utterly bewildered, reinforcing this compliment by adding that had he experienced such an evening at the start of his photographic career, rabbit breeding might have been substituted. The thought is appalling—especially from the rabbit's point of view.

After some desultory but appreciative remarks from others, enters the "office boy" with glee writ large on his countenance. With real sorrow he had noticed that the lecturer had repeatedly referred to potassium bichromate as the *light-sensitive* salt in the carbon process, a mistake which no baby in arms would dream of making. Personally, he did not pretend to be a chemist, but had read an editorial statement in a recent issue of the "B. J." to the effect it is incorrect to allude to the salt as "light-sensitive."

In turn, wreathed in smiles, up rose Mr. Purkis, thumped two heavy volumes on the table and proceeded to read the following extracts, much to the discomfiture of the prior speaker, who made bitter allusions to photographic journalism in general. According to Vogel, "the salt is sensitive to light, but not changed," though as the author was writing in a popular sense, the lecturer said, the wording, in strictness, required amplification. Wilhelm Ostwald, one of the greatest chemists of the world, points out that "sensitive chromic mixtures are not to any extent sensitive to light, but become so in high degree when they are in contact with organic matter." "I therefore maintain it is perfectly correct to say that bichromate of potash is the sensitive salt in the carbon process," triumphantly concluded Mr. Purkis.

This week the "Walrus" is due, on "a subject to be announced." Those at the Photographic Fair who may have noticed him in the vicinity of the telephone call-boxes must also have noticed a certain preoccupied air, entirely due to the fact that up to then he had struck no definite idea on a subject for Croydon.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given, pursuant to Section 242 (3) of the Companies (Consolidation) Act, 1908, that, at the expiration of three months from April 29, the name of Park's Press Photographic Agency, Ltd., will, unless cause is shown to the contrary, be struck off the Register of Joint Stock Companies, and the company will be dissolved.

NEW COMPANIES.

GLOBE DRUG CO., LTD.—This private company was registered on April 26 with a capital of £2,000 in £1 shares. Objects: To carry on the business of chemists, manufacturers of photographic instruments, etc. The first directors are:—A. J. Espley, 64, Higher Antley Street, Accrington (permanent governing director), and S. J. E. Bourn, 95, Conway St., Birkenhead. Registered office: 18, Blackburn Road, Accrington.

DONALD LOCKWOOD AND CO., LTD.—This private company was registered on April 27 with a capital of £1,500 in 1s. shares. Objects: To carry on the business of manufactnrers of and dealers in proprietary articles of all kinds and of photographic apparatus and materials, etc. The first directors are: D. R. Lockwood, Glenwood, Broom Road, Hampton Wick, Middlesex; B. Sherman, 87, Holmesdale Road, Hampton Wick, Middlesex. Registered office: 21, Sugar House Lane, Stratford, Essex.

SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.—Mr. P. R. Salmon was elected president of this Society at the annual meeting, held on 27th ult. The Society was founded fourteen years ago by Mr. John Nixon, who was its first secretary, and for the past nine years its president. Mr. Salmon has been a vice-president from its start. Mr. H. D. Fretwell, Bexley House, The Grove, Greenwich, S.E.10, was re-elected hon. sec.

SANDS-HUNTER CAMERAS.—A 64-page list of new and second-hand cameras at bargain prices just issued by Messrs. Sands, Hunter and Co., 37, Bedford Street, Strand, London, W.C., marks a policy which is observable elsewhere of issuing class or departmental lists. The catalogue is limited to cameras and a few other accessories, such as changing boxes, shutters, and tripods. It is therefore of special interest to the amateur purchaser who buys his hand-camera all complete for use, and, as a rule, prefers not to go to the trouble of having this or that lens specially fitted. For the legion of these purchasers Messrs. Sands, Hunter offer an extraordinary variety of folding plate and film cameras, including a wide selection of those in the vest-pocket and $3\frac{1}{2} \times 2\frac{1}{2}$ sizes. But the professional photographic worker should also note the exceedingly ample choice here offered of reflex and folding focal-plane cameras. The list is one which brings the facility of purchasing from a large stock of reliable goods to the door of the intending buyer, who can obtain the catalogue free on application, and particular goods on approval for five days.

News and Notes.

THE CITY SALE AND EXCHANGE is exhibiting prodigious energy in the publication of catalogues. We have before us the third issued within the last few weeks, and itself a book of nearly 200 pages. It comes to us from the branch of the firm at 54, Lime Street, London, E.C.3, and a copy will be sent to anyone on application to that address.

CANADIAN PACIFIC PHOTOGRAPHS.—On the library floor of the Canadian Pacific Railway building, 62, Charing Cross, London, an exhibition of pictures by Mr. P. A. Staynes, R.O.I., taken by him during a tour in China and Japan, together with a fine series of photographs in colour taken in Canada by Miss Olive Edis, F.R.P.S., will be on view from May 2 to May 16 between 10 and 5 p.m. (on Saturdays, 10 to 1).

MAWSON PLATES.—The Mawson Co., Ltd., 81, Northumberland Street, Newcastle-on-Tyne, send us their revised price list of dry plates, including the "Super-Gladiator," noticed on another page of this issue. With the exception of the firm's X-ray, panchromatic, and "Wizard" (anti-halation) plates, their brands are uniformly priced on a basis represented by 2s. 6d. per dozen in quarter-plate size, 5s. in half-plate, and 10s. 6d. in whole-plate.

JIFFY PASTE.—Messrs. The Binney and Smith Co., 6 and 7, Stonecutter Street, London, E.C.4, send us a sample of an adhesive in powder form which simply requires mixing with cold water to form a powerful paste. The paste is recommended for newspaper wrapping, paper box making, and though its suitability for photographs is not mentioned it appears to be a very clean product, and more suitable, at any rate, for the cheap enlargement trade than many of the cheaper pastes which we have seen. A sample may be had on application to the Binney and Smith Co.

THE CLUB PHOTOGRAPHER is the title which our friends of what hitherto has been "The Northern Photographer," will adopt for their new volume commencing with the June issue. The name has been chosen from many suggestions submitted in competition for a prize, in reference to the wider appeal which the little magazine is intending to make among members of photographic societies throughout the country. A feature of the first issue of the "Club Photographer" is to be articles and illustrations entirely supplied by the Hampshire House Photographic Society.

CINEMATOGRAPHY FOR PROFIT.—Messrs. Butcher have just issued a booklet directing the attention of professional photographers to the opportunities which, on an increasing scale, are being afforded for the supply of films of local interest to cinema theatres. The theatres are glad to have these films for exhibition, but are not in a position to make them. Messrs. Butcher's list contains notes on this outlet for business and shows the equipment with which it can be done. The list is obtainable free on application to Messrs. Butcher's cinematograph branch, 28, Denmark Street, London, W.

HALF-WATT PROJECTION LAMPS.—A small descriptive price list of a very special kind, and one of interest to all makers of enlargements, reaches us from Cinema Traders, Ltd., 26, Church Street, Charing Cross Road, London, W.1. It, is a catalogue of focus-lamp outfits for projection lanterns of all descriptions and shows the various patterns of stands or trays for these lamps specially designed for accommodating them in lantern bodies and for providing the necessary adjustment of the position of the light. Means are also provided for the use of reflectors, increasing the power of the light by approximately 50 per cent.

ENSIGN CAMERAS.—The high cost of printing is evidently restraining manufacturers from issuing the large catalognes which were common a few years ago, but perhaps that is not altogether a drawback when the outcome is the publication of such excellent departmental lists as one just issued by Messrs. Houghton of Ensign cameras and accessories. It is a publication of 160 pages which fully describes and illustrates the Ensign manufactures, from the inexpensive "Mascot" cameras to the lordly "Sanderson." Its pages show the range of cameras for all descriptions of photography which carry the Ensign trade mark in significance of their manufacture in Messrs. Houghton's works.

DEALERS' WINDOW DRESSING.—Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C., have recently organised a most complete service of help for the display of goods in dealers' windows. A booklet shows actual photographic reproductions of a considerable number of window arrangements with lettered plans for the placing of the goods on stands or brackets, which are supplied by Messrs. Butcher. This programme of creating sales is planned in connection with the series of catalogue booklets and show-cards supplied by Messrs. Butcher, and moreover includes electros of photographic advertisements which a dealer may insert in his local newspaper.

BARKAY REFLECTORS.—A descriptive catalogue of these new reflectors for studio artificial sources of light has at length been published by Messrs. W. J. Bartholomew and Co., 40, Gerrard Street, London, W.1. It contains the report by Mr. H. M. Lomas, F.R.P.S., on his tests of the sevenfold increase of light produced by the reflector. The latter, it should be noted, acts by directing the light from an arc lamp or a half watt along a certain but wide path instead of allowing it to be scattered in all directions. Thus, while it produces greater intensity of light the light is still a soft one compared with that from an unscreened light-source. The catalogue illustrates the several patterns of reflector and fittings which can be obtained, and contains a list of some of the notable photographic studios which have installed this important and valuable adjunct to artificial lighting.

QUARTZ LENSES.—The Hanovia Lens Laboratories, Newark, New Jersey, have issued an illustrated price list of the quartz lenses, to which we drew attention some months ago on the strength of the experience with one of the first to be made, published by Dr. D'Arcy Power, of "Camera Craft." The lenses are now issued in two series, of *f*/4.5 and *f*/6.3 aperture, under the name of "Kalo-sat." In the *f*/4.5 series they are made in focal lengths from 6½ inches to 13½ inches for plates from 5 × 4 to 10 × 8. The prices range from 24 to 115 dollars. In the *f*/6.3 series, similarly priced for the same series of plates, the focal lengths, rather curiously, are longer, from 9½ inches to 19 inches. A special characteristic of these lenses is their greater rapidity, aperture for aperture, owing to the higher spectral transmission of the quartz. The definition also is one of a peculiarly pleasing soft character when the full aperture is used.

Correspondence.

*** *Correspondents should never write on both sides of the paper.*

No notice is taken of communications unless the names and addresses of the writers are given.

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

HALATION AND DEVELOPMENT.

To the Editors.

Gentlemen,—May I contribute a few words to your discussion on halation? I quite agree with your correspondents who advocate the use of a strong developer. Some time ago a friend of mine took some photographs of some birds in the Botanical Gardens here. The house in which they were has glass roof and side; the day was extremely bright, and, in consequence, short exposures were given. I think most of them were exposed for only the 25th of a second. On developing these, several of which included large portions of the glass side and roof, I was surprised to find no trace of halation. The developer I used was pyro soda, which had accidentally been made too strong a solution. It never occurred to me that the absence of halation was due to this fact until I saw the controversy in your journal.

The plates used were Wellington Anti-screen. In my opinion self-screened ortho plates have less tendency to the giving of halation than the ordinary plates have. Personally, I have been disappointed with films. They seem as bad as plates with the exception of one or two particular makes, for instance, Portrait Film, where the emulsion, being thick, seems to give better results than ordinary unbacked plates.—Faithfully yours, J. J. GROVER.

Temple House, Bath Row, Birmingham, April 23.

DESENSITISING AND PANCHROMATIC PLATES.

To the Editors.

Gentlemen,—Mr. Crowther's article in your issue of the 22nd is of great interest to amateurs like myself, but does not lead us much farther with the question of avoiding the red stain due to Desensitol. The stain is sometimes patchy or uneven in tint, and occasionally, as Mr. Crowther remarks, a bluish violet tint will appear on drying an apparently stainless negative. Such negatives are spoiled for printing or enlarging.

I have further found the alteration in Watkins factor noted in the article, and am glad to see it explained. Mr. Crowther speaks also of desensitising backings, and it may be of interest to your readers to learn that I accidentally found this to happen when developing some red-backed Anti-Screen plates, though at the time I ascribed the absence of fog as due to the protective red colour of the developing bath caused by the solution of the red backing.

I have concluded that until we know more about the use of Desensitol I can get on better by developing by the factorial system with a Wratten Green safe-light for panchromatic plates. Although the Ilford Company state that their panchromatic plate is unsafe in any light, I have successfully developed some of these plates with pyro-soda, using a Wratten safe-light and factorial development. All negatives are bright and clear, and no fog is apparent in any one of them.—I am, sir, yours faithfully,

HENRY N. HOLLAND.

13, Cawdor Road, Fallowfield, Manchester.

THE CONGRESS—AND NOW.

To the Editors.

Gentlemen, After a well-attended and most successful Congress—particularly under the existing difficult circumstances—I would ask my brother professional photographers, through your kind indulgence, not to hesitate in becoming members of the P.P.A. Cogent matters, requiring strength of numbers and unity of purpose, are coming to the fore with which the *combined* efforts of those making their livelihood by photography are necessary to cope, and I beg my professional brethren not to stand passively looking on—as four-fifths of the profession are doing at the present moment—while the 24 men constituting the P.P.A. Council do the work.

There is a saying that "actions speak louder than words," and if the labours of the Council are worth anything at all, surely they are worth encouragement. The London Councillors are on the spot, like permanent men of a fire brigade, and are always at P.P.A. work. The country men, too, spend time on looking after its interests, in addition to the expenses incurred by attending Council meetings, and their expenses average, I should say, *quite ten pounds* per annum per Country Councillor, in *railway fares alone*. Your non-member of the P.P.A., when pressed to join, often asks, "What will it benefit me?" Well, to what extent does it benefit men on the Council? What do they get for their work? What do they ask for? *Encouragement*, that is the word; encouragement to look after his interests, for which he is asked to pay 10s. per year, while some of these men spend *more than ten pounds* a year for that particular purpose.

We are supposed to number 5,000 or more professional photographers in the United Kingdom. The membership of the P.P.A. stands at a little over 1,000—when it ought to be four times as many. Come, men, buck up! The subscription will not break you, even if times are hard, and later on you will be glad.—Yours, etc.,

FRANK BROWN,

Ex-President, Professional Photographers' Association.

Leicester, May 2.

TECHNICAL JOURNALS.—When felicitations are offered to our confrère, Mr. Arthur C. Brookes, on the organisation of a Fair, or the regular publication of his trade journal, it is perhaps not remembered that Mr. Brookes carries also on his shoulders the responsibility for the management of the British Association of Trade and Technical Journals, a body representing the interests of a very large number of technical periodicals. The official handbook, just issued at the price of 1s., of this Association, contains particulars of these periodicals, such as subscription rates, advertisement tariff, and character of circulation. It provides a most useful conspectus of the technical press for the purposes of the large or small advertiser.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

B B.—In some districts the police require a canvasser for photographs to have a hawker's licence, but in other districts, according to our experience, this is not the case. The only thing you can do to make sure is to apply at the local head police office in the district where you are working.

F. T.—Aluminium is most unsuitable for developing solutions, and not by any means the best for fixing baths. You can improve matters by covering the metal with ordinary quick-drying enamel, but a better material, though more expensive, is the so-called anti-sulphuric paint sold by dealers in electrical requisites.

A. S. F.—We think the text book "Optical Projection," by Russell S. Wright, published last year by Messrs. Longmans, Green and Co., 39, Paternoster Row, London, E.C.4, price 4s. 6d., would give you the information you want. It is only a small book, but it deals fairly thoroughly with arc lamps, and Mr. Wright is a thoroughly practical lanternist.

F. A.—(1) Nothing better for preserving gum arabic than thymol, a few grains per ounce of the mucilage as required. (2) We are afraid we cannot express an opinion, for the Rents Act is such a complicated thing that you should apply to one of the daily papers, such as the "Daily Chronicle," which keeps a barrister engaged in answering queries relating to it. But we don't think they could turn you out.

T. C.—We are afraid it is very difficult to ventilate the room satisfactorily except by putting the lamp outside. Could you not make the shutter blocking up the window with some kind of covered box on the outside so that you could put the lamp in it sufficiently sheltered from draught and so escape the bad effects of it in the room? As the window is so small we do not think any pair of ventilating passages—one on the top and one at the bottom—would be any good.

G. S.—(1) Preventive means as also susceptibility to amidol poisoning vary considerably with each individual. Generally speaking, about the best preventive means is to dip the fingers into plain water, or into water just made acid with a few drops of hydrochloric acid, every time they have been in the developer. Regular use of an emollient, such as Hazeline cream, is also a preventive, but nothing that we know of can be said to be an absolutely certain or effective preventive for a given individual.

C. L.—(1) Using a wide-angle at its maximum aperture, usually of *f*/16, the shortest focus which it is wise to use for covering a half-plate is about 5 inches. If you are ready to stop down to *f*/32 you can cover a half-plate with an *f*/16 W.A. lens of about 4½ inches focus. The above applies to the ordinary types of wide-angle lens. There is also the "Hypergon" wide-angle, not now on the market, but no doubt obtainable second-hand, which would allow of a much shorter focus, probably less than 4 inches for half-plate.

A. R.—Your room is rather low for a studio, and some ingenuity will have to be exercised to get your front lamps high enough for groups and standing figures. We should estimate that you will require about 8,000 c.p., and for groups it must be well distributed. The lamps should all be made to raise and lower so that you can shorten the exposure with sitting figures and children. As you arrange in your diagram you will have the lights on the wrong side of the studio for the majority of faces. If you can work the other way round it will be better. You can shift the 2,000 lamps to where you want them for any special subject.

C. M.—Providing that the projection lens is of appropriate focal length to your 8½-inch condenser, that is about 8 to 9 inches focus, there is no useful purpose in having the negative carrier frame movable to and fro between the condenser and the objective, except for the purpose of shortening the exposure when enlarging very much smaller negatives than the full half-plate covered by the condenser. If you move the little negative further away from the condenser you get a more concentrated beam of light on it, and so shorten exposure, which may at times be an advantage, at any rate for dense negatives or when using slow papers. In this case a useful amount of movement would be one-third to one-half the distance between the condenser and the objective.

H. S. G.—(1) There is no means of calculating the quantity of potassium carbonate equivalent to a given weight of sodium carbonate in a developer. You can only go by the quantities of these alternative alkalies prescribed in specific formulæ. (2) No doubt silver nitrate keeps better in an amber bottle, but experiments made some years ago showed that the developers do not keep any better, and, in fact, in some cases, keep better in a bottle of blue glass than in one of amber. (3) The only "secret," if it can be called one, is that a reflex camera in which the mirror is raised by mechanical means is much more satisfactory as regards smoothness of working and uniformity of action than one in which the mirror is raised by the human user, as is the case with most of the cheap models.

L. B.—We had better deal generally with your two queries together by saying that we think it is bad practice to use daylight for illumination of the dark-room. One inconvenience is that a light which is safe at one time may be unsafe half an hour later owing to changes in the outside light. Also the fabrics, through constant exposure to daylight, are gradually bleached to some extent, and you never know when the bleaching has reached a point at which the fabrics become unsafe as filters. On both of these accounts it is far better to use a gas or electric dark-room lamp fitted with one or other of the tested safelights supplied by Messrs. Kodak, Ilford, and others. However, we should say, as a kind of guess, that two thicknesses of commercial ruby fabric would provide a reasonably safe illumination for the handling of films, but you would probably want one ruby and one yellow for handling bromide paper. Yellow alone would not be safe for bromide. You could, of course, cover the glasses of the window with a dye varnish, but it would be a messy job, the dyes would always be exposed to full daylight and you couldn't get a full flood of daylight in the room. We think this plan is the least advisable of those you mention.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3184. Vol. LXVIII. FRIDAY, MAY 13, 1921. Price Fourpence.

Contents.

SUMMARY

In a communication from the Eastman Research Laboratory Messrs. Loyd A. Jones and C. E. Fawkes have recorded their experiments on the relative suitability of different reducing formulæ for diminishing the depth of gaslight prints and of prints on other development papers. They point out that reducers in some cases act differently upon prints and negatives, and that the different properties of reducers which are in common use are adapted for various specific effects in reduction. (P. 275.)

In a leading article we emphasise some of the practically useful results contained in the paper, among them the value of the reducer compounded with both ammonium persulphate and potassium permanganate, which, especially has the effect of undoing, so to speak, the effect of excessive development. (P. 274.)

In a contributed article "Thermit" suggests that living organic matter in water is liable to produce stain on gelatine papers which at some stage of their production have been treated with alum. (P. 278.)

In his "Paris Notes," M. L. P. Clerc refers to the present need in France of systematic instruction in photography. He also describes some recent work by MM. Lumière on desensitisers, a new three-colour camera, cinematograph film printer, and directs the attention of photographic societies to an experiment in stereoscopic vision. (P. 279.)

£1,000 in prizes for professional photographers and their sitters is to be awarded by Messrs. Wellington and Ward in a competition. (P. 282.)

Mr. Walter Thomas is showing examples of his professional photography at the Davis Galleries, New Bond Street, during the present month. (P. 282.)

The Edinburgh Society of Professional Photographers has issued a costing schedule for the information of its members undertaking commercial photography. (P. 285.)

Inspectors under the Shops Act should take a hint from their colleague at Aberdeen who has been to the trouble of notifying photographers of their rights in respect to making portraits by appointment at the studio on the week's half holiday. (P. 273.)

An obituary notice of the late Mr. W. Friese-Greene, whose sudden death last week has received much notice in the daily Press, will be found on page 281.

A remarkable case of a printable negative produced by six weeks' exposure on an outdoor subject is mentioned on page 288.

At the Croydon Camera Club last week Mr. W. L. F. Wastell gave a good deal of practical information on the use of "Transferotype" paper. (P. 285.)

Notes on the design and use of simple soft-focus lenses are contributed by correspondents. (P. 287.)

New formulæ for the Carbro process have been published by the Autotype Company. (P. 281.)

EX CATHEDRA.

Posing Chairs. We do not know whether there are any photographers who are investing money in furniture at the present juncture, but if such there be, they should bear in mind that a chair needs to be something more than attractive looking to be of the greatest utility in the studio. Many chairs have a tendency to cause the sitter to have a "bunched up" appearance, due to their being too low. For bust portraits and three-quarter-length ordinary poses the seat should always be high enough to keep the knees well below the line of the thigh bone. The height of the seat also has a considerable effect upon the pose of the shoulders, so much so that some workers advocate a standing position for head and bust portraits. When selecting a chair it is a good plan to secure the services of a lady who will act as a model and test the possibilities of the article by sitting in it. It will often be found that very graceful-looking (chair) arms come very awkwardly in the way in certain poses. Two or three small tightly-stuffed cushions will be found of great value for increasing the height of the seat to suit the pose and the figure of the sitter.

* * *

Half-day Closing. We must say a good word for Mr. James Cumming, chief inspector under the Shops Act in Aberdeen. We do so because Mr. Cumming has gone to the trouble of issuing a circular letter notifying photographers of their freedom to take portraits by appointment on the afternoon in the week which is the statutory half-holiday under the Shops Act. The circular letter runs as follows:—"On 18th March one of the photographers in the City drew my attention to a paragraph which appeared in 'Answers to Correspondents' column of the 'British Journal of Photography,' dated 21st January, to the effect that it had been definitely stated by the Home Office that the taking of portraits by appointment at a studio on the weekly half-holiday was not contrary to the Shops Act. I immediately communicated with the Under Secretary for Scotland asking whether the information referred to was correct. As I had not received a reply up to 27th April, I again wrote him on that date, and have now been informed 'that the statement is substantially correct, and is based on the view (from which the Secretary for Scotland sees no reason to dissent) that the actual taking of a photograph is part of the process of manufacture.'" Such consideration of those coming within their inspection is so rare a quality of the official mind that the citizens of Aberdeen are to be congratulated on the sensible point of view of the officer in question. Other inspectors charged with administration of the Shops Act may be advised to follow his example. Since there has been a definite expression of opinion by the Home Office, it is plainly to the interest of both inspector and inspected that the fact should be made as widely known as possible.

Finders It is not always easy to see the image in the finder of a hand camera unless it happens to be a reflex, or the eyesight of the photographer is unusually acute. With practically all types of finder, either direct vision or reflecting, the short-sighted person is at ease, but when the slightest tendency to hypermetropia is present there is a difficulty in seeing the finder image clearly, unless "reading" spectacles are worn. These, however, preclude a clear view of the actual object or view to be photographed, so that it is better, if possible, to arrange a magnifying lens as an attachment to the finder. An ordinary small magnifying glass of the linen-prover type can be fixed over either a ground glass or "brilliant" finder, so that it will fold flat when not in use, while those who prefer a direct-vision finder will do well to select one that has a small magnifying lens fitted in place of the usual sighting vane. If this is not done the eye must be kept so far from the concave lens that a much smaller field than that of the camera lens is covered. The ordinary wire-frame finder fitted to some focal-plane cameras is, perhaps, the most satisfactory arrangement, as although the wire may not appear quite sharp, it is sufficiently so for all practical purposes.

THE PROPERTIES OF REDUCERS FOR BROMIDE AND GAS-LIGHT PRINTS.

In these days of almost endless variety in printing media—variety which allows of passable prints being obtained from negatives which would, even a decade ago, have been transferred straight from the fixing bath to the waste box—it is somewhat of an irony that exact knowledge of the nature of that appearing in the communication which we print to-day by Messrs. Loyd A. Jones and C. E. Fawkes should become available. But even with the present wide choice of papers to suit any negative, it sometimes happens that the results are not quite up to the standard quality on which the professional's reputation depends; and should the prints happen to be enlargements, the knowledge of how to correct them by intensification or reduction becomes of intrinsic value. As far as intensification is concerned, the now well-known chromium process leaves little to be desired, for not only is the permanence of the intensified print equal to that of a pure silver image, but also the colour of the image is usually much improved by the process.

Those who have made a study of the matter do not hesitate to affirm that the majority of present-day printers habitually over-expose, with the result that unless great care is exercised in the timing of development, the prints are degraded by being developed too long. It should further be remembered that even an acid fixing bath does not instantly stop the developing action of amidol, so, from one cause or the other, it frequently happens that treatment with an appropriate reducing solution would noticeably improve matters. Hitherto, the problem has been to find the appropriate reducer, for until definite measurements of the alterations effected by the various available reducing solutions had been made, only the usual confusion of ideas and terms could be expected to exist. Taking advantage of the possession of apparatus of proved accuracy, Messrs. Jones and Fawkes have investigated the action of all the well-known reducers on typical hard, soft and normal development papers. Their results indicate that it is possible not only to undo the effects of over-development, but also to compensate for errors arising from the use of an unsuitable printing paper. They have demonstrated, for example, that certain reducers in the early stages of their action produce no change of contrast in the tones of the print and that continued action of the solution effects a diminution of contrast which tallies exactly with that exhibited at various stages of the original development of the print. Again, it is evident from the curves which form a valuable portion of the communication that reducers like iodine-cyanide and the Howard-Farmer actually increase the contrasts of the print, a fact which has long been known in a general sort of way by most practical workers who by the use of one or the other of these solutions for clearing "sketch" portraits effectively emphasise the outlines of the subject by cutting out the lighter half-tones. Apart from the slight staining of the gelatine by the Farmer reducer, it appears that there is little to choose between this and the highly-poisonous iodine-cyanide solution. Indeed, if the respective solutions be made up in the rough and ready way usually adopted by busy photographers, the Farmer solution is to be preferred on account of the well-known softening of the gelatine induced by potassium cyanide solution.

Perhaps the most interesting information contained in the communication is that which deals with the "proportionate" reducer, a solution containing both ammonium persulphate and potassium permanganate. It will no doubt be recollected that this mixed solution was investigated for negative reduction at the suggestion of a correspondent of this journal, Mr. N. C. Deck, and was found to fill a long-felt want. From personal experience we can strongly recommend it; the small quantity of sulphuric acid which is present in the permanganate portion of the mixture renders the action of the persulphate very smooth, and by variation of the proportions of the two solutions almost any type of reduction can be secured at will. It is now found that prints can be treated with this reducer without any staining occurring and that the reduction effected is truly proportional. This information is, of course, of little interest to the printer who has the misfortune to be working in "Quantity Street," but to the assistant who aspires to the possession of his own establishment in "Quality Street," it means much, for a few trials on waste prints will soon indicate whether choice of paper, exposure or development is responsible for the existence of such waste prints. By referring the modified prints to the original negatives an excellent guide for future manipulation in the quest of the best result procurable will be obtained. Although no reference is made in the text to the matter, it should be pointed out that a sulphite stop-bath must not be omitted after reduction with persulphates.

The effect of the addition of chlorides or soluble silver salts to the persulphate reducer is of particular interest, for although it was well known that these substances interfered in some way with the characteristic depth reduction of persulphate solutions, the fact that the presence of 1 per cent. of sodium chloride brings persulphate into the class of proportionate reducers, as is so well shown in figs. 9 and 10 in the communication, is new knowledge which cannot be disregarded by either the practical worker or his scientific confrère who is responsible for the formulation of acceptable theories. At some future date, perhaps, Messrs. Jones and Fawkes will deal with the persulphate-hypo reducer recommended by T. H. Greenall, as it would be interesting to know whether the addition of the hypo, which keeps the silver in solution as it is acted on by the persulphate, has the same effect as an initial addition of a soluble silver salt, or whether it acts in a contrary direction to chlorides, which cause precipitation of the silver immediately it has been dissolved by the persulphate.

A SENSITOMETRIC STUDY OF THE REDUCTION OF GASLIGHT PRINTS.

(A communication from the Research Laboratory of the Eastman Kodak Co.)

The action of photographic reducers upon the silver deposits in photographic plates and films has been studied rather extensively by various workers in the field of photographic research. These investigations have been carried out both from the practical and theoretical points of view. Among the most prominent researches of this nature may be mentioned those by Lüppo-Cramer,[1] A. and L. Lumière and Seyewetz,[2] Stenger and Heller,[3], Deck,[4] Nietz and Huse,[5] and Sheppard.[6] Practically all of this work has dealt with the reduction of density in the case of photographic materials coated on transparent supports, such as plates and films, for not until a satisfactory method for paper sensitometry[7] was available could the usual H. and D. methods be applied to the study of the reduction of density in photographic papers.

Since it is evident that the quality of the photographic print may in some cases be improved by the proper reduction of density, it seemed advisable to investigate the effect of various reducers when used for this purpose. The problem is considered in this paper entirely from the sensitometric standpoint, very little attention being paid to the theory of the action of these reducers on the deposits, and all conclusions relative to the merit of the various reducers tried are based upon the consideration of the sensitometric curves rather than upon actual prints. The sensitometric method for the study of the characteristics of photographic materials has

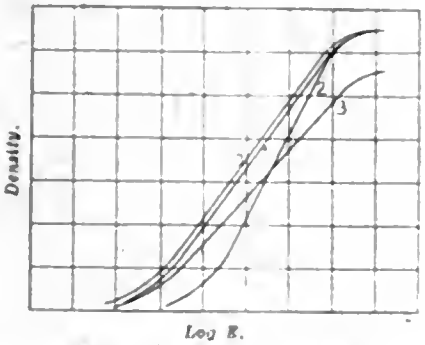

Fig. 1.—Types of print reducer.

been discussed at length in previous papers (footnotes 5, 7 and 8), and to these the reader is referred for the details of such methods.

Excessive density in all parts of the print or in certain limited regions may result either from over-exposure or over-development of the print or because a paper of the proper contrast was not used in making the print. It is doubtful if reduction can completely correct the latter defect, but certainly some improvement may be effected. From a consideration of the shape of the characteristic curves of various papers, it will be seen that in order to improve the quality of the print in some cases reduction of density should be such as to cause a decrease in contrast, while in others the reduction should increase the contrast, while a third possibility may require reduction which will reduce the density in such a way that no change in the contrast is produced. These three general types of reduction may be illustrated by the curves shown in fig. 1. Thus, if we consider the curve 0 as the characteristic of the material considered, then curve 1 will represent the result when this material is subjected to the action of a reducer producing no change in contrast. Such reducers will be referred to as Type 1. Curve 2 represents the result when the same material has been subjected to a reducer which produces an increase in contrast, this increase in contrast being caused by a more vigorous action of the solution upon the low densities than on the high.

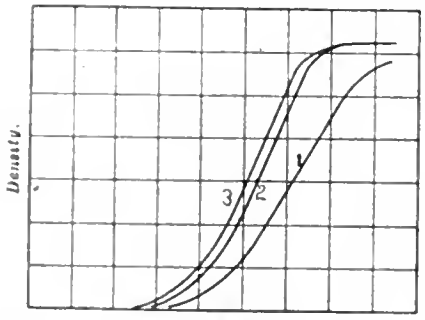

Fig. 2.—Characteristic curves of development paper.

Reducers of this kind will be referred to as Type 2. Curve 3 represents a case of the decrease in contrast, and results from the proportional reduction of all densities regardless of their magnitude; that is, each density is reduced to the same percentage of its original value. Reducers having this action will be referred to as Type 3. No distinct line of demarcation can be drawn between these various types, since some reducers have characteristics intermediate between those represented by the typical curves in fig. 1.

In fig. 2 are shown the characteristic curves of Iris Artura paper. Curves, 1, 2, and 3 represent the change in density with increasing times of development. From the shape of these curves it is possible to draw conclusions as to the action of the reducer which can be used successfully to correct over-development in the case of this material. It will be noted for the longer times of development that for the correction of over-development a reducer of Type 1 will be necessary, while if it be desired to obtain results comparable with those resulting from under-development in such a print a reducer of Type 3 will be required. In fig. 3 are shown the characteristic curves of Velox, the different curves representing increasing times of development. It will be noted in this case

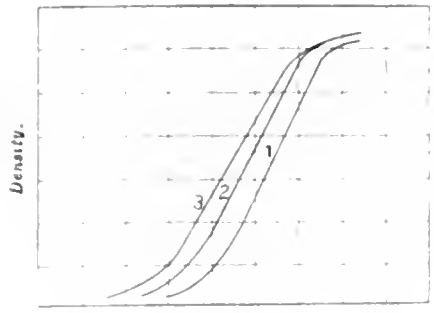

Fig. 3.—Characteristic curves of Velox paper.

that for the correction of over-development a reducer of Type 1 is necessary.

Ten reducer formulæ were chosen principally from the "British Journal Almanac," and prepared full strength. The list included permanganate, bichromate, Eder's and iodine-cyanide, whose action upon negatives is of Type 1, corresponding to the curve shift 0 to 1 (fig. 1). Farmer's

and Belitski's reducers were selected as being typical of Type 2, while sodium hypochlorite, ammonium persulphate and the Nietz-Huse proportional reducer were taken as representative of Type 3. As typical examples of the developing-out papers, the following were chosen:—

Paper.	Grade.	Relative speed.
Azo	E-Hard X	Medium Fast.
Velox	Regular Velvet	Very Fast
Artura	Iris B	Slow

These papers were exposed in the non-intermittent sensitometer in the usual way, and strips consisting of twenty-six steps increasing in exposure by consecutive powers of the cube root of two were obtained. These exposed strips were then developed in the recommended solutions so as to obtain normally and over-developed results.

A number of preliminary tests were made with each reducing solution to find the dilution necessary to obtain uniform and controllable action. From these preliminary tests the most satisfactory concentration for use in the subsequent study of reduction was determined. These dilutions and the formulæ are given later in this report. All reduction was carried out at a temperature of 20 deg. C. Careful observations were made relative to the colour of the deposit resulting from the action of the reducing solutions for various lengths of time, and also upon the staining of the image and gelatine by the reducers and their reaction products. Some staining was observed, but in those reducers which were found to be otherwise satisfactory it was possible to remove these stains by returning the print after reduction to the ordinary acid fixing bath for a short time, this, of course, being followed by washing and drying in the usual way. After being reduced, the reflecting power of the various areas of the sensitometric strips were read on the reflectometer and the characteristic curves plotted in the usual way. These curves were then compared with one plotted from the results obtained from the non-reduced strip. By a comparison of the curves thus obtained information is secured from which it is possible to predict the action of the various reducers upon prints.

Reducers of Type 1.

1. *Potassium Permanganate.*—This reducer converts the silver of the deposit into silver sulphate, which is soluble in the solution. The reduction is rapid, and no stain is produced either in the silver deposits themselves or in the gelatine. With prolonged action it gives a slightly grainier appearance to the areas of low density. In fig. 4 is shown a

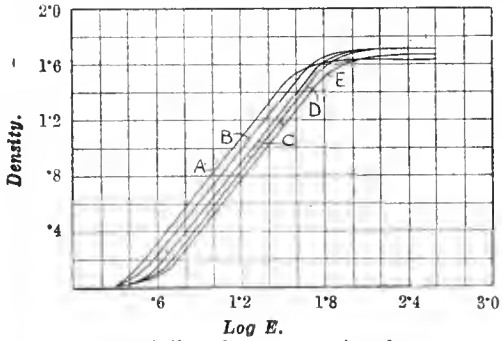

Fig. 4.—Action of permanganate reducer.

series of curves obtained with this reducer on Artura paper. It will be noted that the straight-line portions are almost exactly parallel to each other. Curve A was plotted from the unreduced strip, while B, C, D, and E were obtained by subjecting identical strips to the action of the solution for 45, 60, 90 and 120 seconds respectively. It will be noted that the maximum black on the reduced strips is apparently higher than that of the unreduced. This is because the densities plotted are measured relative to the fog density of the paper. The action of the reducer cuts away this fog density and tends to give slightly higher maximum density when measured against the unexposed regions of the paper. The action of this reducer on Velox and Azo is the same as that on Artura (as shown in fig. 4), with the exception that in the case of Velox there is slightly more reduction of the high-light regions. This reducer, as shown by the curve in fig. 4, is an almost ideal corrective for cases of over-development.

2. *Belitski's Reducer.*—The image is converted by the ferric oxalate and soluble chloride solution to silver chloride, which

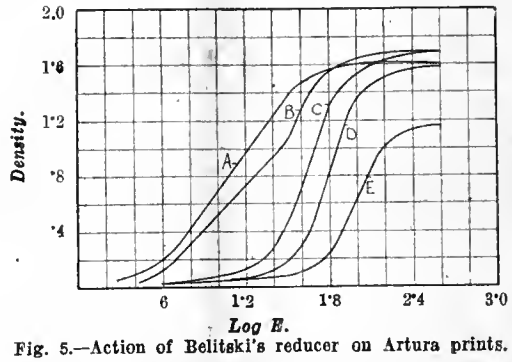

Fig. 5.—Action of Belitski's reducer on Artura prints.

is then dissolved by the hypo in the reducer. The action is very rapid at the concentration recommended, and, although stainless and uniform in action, it seems to give a slightly brownish coloured deposit when the reduction is carried to any length. In the case of slight reduction this tendency to give brownish deposits seems to be entirely absent. On Artura it acts as it does on negatives, giving a transforma-

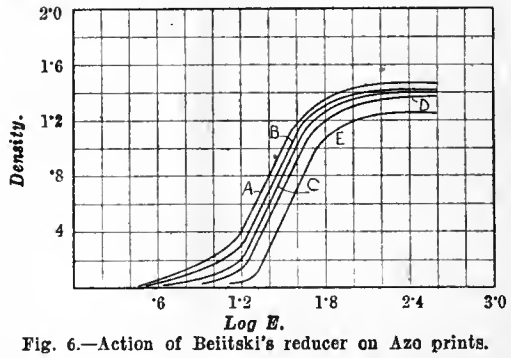

Fig. 6.—Action of Belitski's reducer on Azo prints.

tion of Type 2; that, is reducing the lower densities more rapidly than the higher ones and therefore giving an increase in contrast. Upon Velox and Azo its action is of Type 1; the straight-line portion of the curve remaining parallel to that of the unreduced strip. In fig. 5 is shown a set of curves obtained from sensitometric strips made on Artura and treated with this reducer, the times of action being 45, 60, 90, and 120 seconds respectively for curves B, C, D, and E. In fig. 6 are given the curves, showing the action of this reducer on Azo. These curves are almost identical with those obtained on Velox. It should be noted that, while the straight-line portion of the reduction curves are practically parallel to that of the unreduced, the high-light densities are attacked more vigorously than those of the half-tone and shadows, thus producing a cutting away of the toe of the curve in the case of the reduced strips.

3. *Iodine-Cyanide.*—This reducer, applied on prints, falls in Type 2. Further reference is made in that classification.

4. *Eder's.*—This reducer was found to be unsatisfactory, owing to the unevenness with which action occurred.

5. *Bichromate.*—This also was found unsatisfactory owing to excessive staining of the gelatine.

Reducers of Type 2.

1. *Iodine-Cyanide.*—The free iodine in the solution converts the silver of the image into silver iodide, which is soluble in the potassium cyanide of the solution. This reducer acts rapidly, uniformly, and is clean and stainless. No mottling effect is noticeable even in the lowest density.

It is, however, extremely poisonous, and therefore it is undesirable to recommend it for general use. In fig. 7 is shown a series of curves plotted from strips made on Artura Iris and reduced in this solution. Curve A is that of the unreduced strip, while B, C, D, and E received treatments of 30, 45, 75, and 120 seconds. It will be noted that the upper portion of the curves are changed very slightly, while the high-light and lower half-tone densities are cut away, producing an increase in contrast. The action on Velox and Azo is identical with that on Artura. During the reduction the paper stock of the print appears a brilliant blue, due

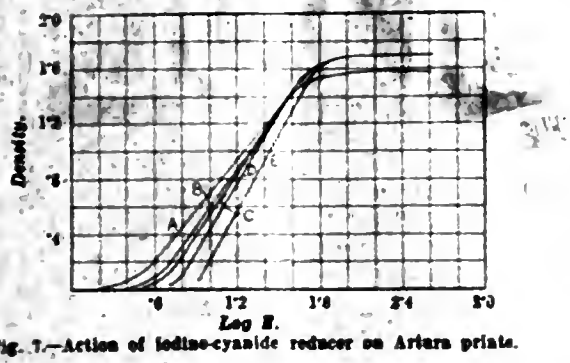

Fig. 7.—Action of iodine-cyanide reducer on Artura prints.

to the presence of starch iodide, which can be completely removed by soaking in an acid hypo solution after the reduction is completed.

2. *Farmer's Reducer.*—The silver is converted by the potassium ferricyanide into silver ferrocyanide, which is soluble in the hypo of the solution. A slight staining of the gelatine was noticed in some cases, but in other respects the action is identical with that of the iodine-cyanide. The curves shown in fig. 7 are typical of Farmer's reducer on all kinds of paper.

Reducers of Type C.

1. *Nietz and Huse Proportional Reducer.*—The reduction in this case is due to a combination of the actions of ammonium persulphate and potassium permanganate. Each reducing agent retains its chemical identity. The permanganate attacks the lower densities while the persulphate is acting upon the higher densities. Used on prints the action is very rapid, uniform, and stainless. Its concentration can be adjusted to any particular paper reduction problem with great ease. In fig. 8a are given curves plotted from

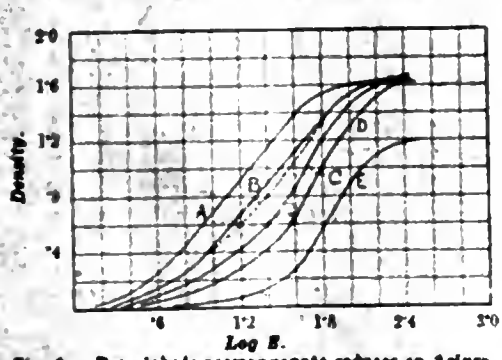

Fig. 8a.—Persulphate-permanganate reducer on Artura

strips made on Artura Iris treated with this reducer. In fig. 8b are shown the results on Velox, and in fig. 8c those obtained upon Azo.

2. *Ammonium Persulphate.*—Various attempts have been made to explain the peculiar action of this reducer. Lüppo-Cramer has advanced a protective colloid theory based on the idea that the chemical composition of the photographic image is dependent upon the exposure. The images having higher density are therefore in some way different from those of lower density, and this difference is of such a nature that the ammonium persulphate reducer attacks densities above a certain critical value very vigorously, while the action of lower densities is almost inappreciable. A catalytic theory of the action has been proposed by E. Stenger, which assumes a selective action on the higher densities due to the presence there of an excess of silver ions. In fig. 9 are

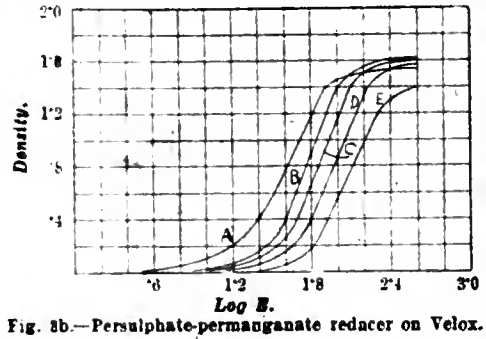

Fig. 8b.—Persulphate-permanganate reducer on Velox.

shown curves illustrating the action of this reducer on the Velox strips. It will be noted that above a certain critical density designated by the point P the action is very vigorous, while for densities lower than that no measurable action occurs. Strips reduced in this solution, therefore, have very peculiar density characteristics. For instance, a strip treated four minutes exhibits a density maximum in the half-tone regions, the shadows being cut away so that they are

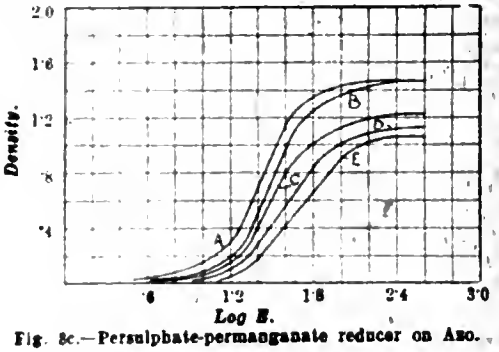

Fig. 8c.—Persulphate-permanganate reducer on Azo.

actually lower in density. It is evident that this reducer is unsatisfactory for most purposes, although it is possible that it may be utilised to advantage in some special cases where it is desirable to reduce the shadow densities without affecting high-light and half-tone regions. By the addition of a soluble chloride or of silver ions (silver nitrate) to the reducing solution the character of the action is changed radically, and the reduction becomes strictly proportional. In fig. 10

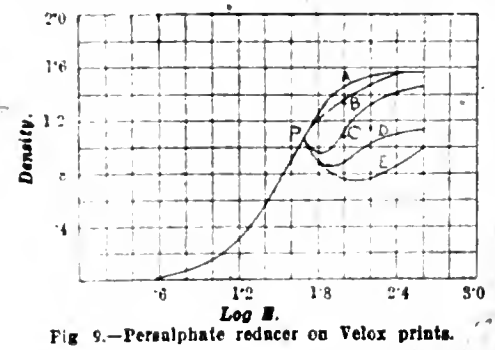

Fig 9.—Persulphate reducer on Velox prints.

are shown the curves obtained from strips made on Velox reduced in an ammonium persulphate solution containing 1.0 per cent. sodium chloride. Curves B, C, D, and E were obtained from strips which had received 2, 3, 5, and 7 minutes' treatment. It will be noted that the reduction is very nearly proportional, the action is uniform, and no

staining of the deposit or gelatine is perceptible. It should be pointed out that the results shown in fig. 9 were obtained by the persulphate reducer when made up with distilled

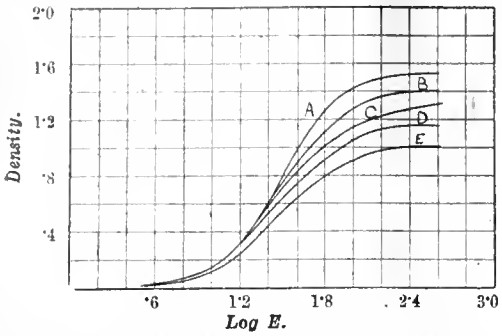

Fig. 10.—Persulphate-chloride reducer on Velox.

water, the only difference in the solution used for obtaining results in fig. 10 being the addition of 1 per cent. of sodium chloride.

Summary.

1. Several reducers commonly used for the reduction of negatives have been studied and modified in such a way as to be applicable to the reduction of prints made on gaslight papers.

2. A classification has been made on the basis of the character of the modification in the characteristic curve obtained with the several reducers.

3. Observations have been made relative to the staining of the deposit and of the gelatine resulting from the action of the reducer and its reaction products, and a means of removing the stain in most cases has been found.

4. The character of the action of a given reducer on negatives cannot in all cases be taken as indicative of what its action on prints will be.

5. Reducing solutions made up according to the formulæ appended to this report have been found to give satisfactory action on printing-out papers, the particular one to be chosen in any case depending upon the modification which it is desired to make in the print.

Formulæ are as follows:—

Permanganate Reducer.

Potassium permanganate	0.5 gm.
Sulphuric acid, 10 per cent.	25 c.cs.
Water	500 c.cs.

Dilution for use, 1 part of solution in 13 parts of water.

Belitski's Reducer.

Ferric chloride, cryst.	6.5 gms.
Potassium (or sodium) oxalate	12.5 gms.
Sodium sulphite	8 gms.
Water	200 c.cs.

When ready to use, add to the above 3 gms. of oxalic acid crystals and agitate the solution until it turns green. Pour the supernatant liquid off the crystals and add to this clear solution 50 gms. of sodium thiosulphate (hypo). Dilute this solution 3 parts in 11 parts of water for working on prints.

Iodine Cyanide Reducer.

Iodine (10 per cent. solution in potassium iodide)	25 c.cs.
Potassium cyanide, 10 per cent. solution	4 c.cs.
Water	400 c.cs.

For paper reduction, take solution 1 part, water 10 parts.

Farmer's Reducer.

Sodium thiosulphate (hypo), 20 per cent. solution	150 c.cs.
Potassium ferricyanide, 10 per cent. solution	50 c.cs.

Dilution for print reduction, 1 part in 3 parts water.

Nietz' Proportional Reducer.

A.	Potassium permanganate	0.125 gm.
	Sulphuric acid, 10 per cent.	7.5 c.cs.
	Water	500 c.cs.
B.	Ammonium persulphate	12.5 gms.
	Water	500 c.cs.

For print reduction, take 1 part A, 1 part B, and 4 parts of water.

Ammonium Persulphate Reducer.

Ammonium persulphate	40 gms.
Water	500 c.cs.
Sulphuric acid	0.53 c.c.
Sodium chloride	0.4 gm.

Dilution for print reduction, 1 part in 2 parts of water.

LOYD A. JONES.
C. E. FAWKES.

AN OBSCURE CAUSE OF STAINING.

Is it possible for germs in tap water to bring about a discolouration in photographic gelatine, the action being dependent upon the presence of a certain chemical?

From recent investigations of a peculiar staining problem I am inclined to believe that it is not only a possibility but a probable cause of quite a lot of staining in prints and negatives. Some little time ago I was badly worried by spasmodic appearances of yellow stain in bromide and gaslight prints. At first I suspected the paper, but found that three different brands of gaslight and four of bromide were all liable. The stain was even and apparently permanent, a great variety of chemicals being used in an endeavour to bleach it, but without result. Exposure to strong daylight had no effect; in fact, the stain seemed to gain depth with age. Suspecting the developer, a brand of amidol, the brand was changed, but without definite results. It was, however, noticed that when a certain brand was used in conjunction with a fixing bath containing acetic acid the staining was worse than ever. A change to metol-hydroquinone was followed for a time by absence of the trouble, but as the weather at the time was very changeable and the normal temperature different every day, the M.Q. was not as good for general work as amidol. Things were improved by the adoption of a heating box made from a tin biscuit box containing a 16 c.p. carbon filament lamp. By using this as a stand for the developing dish, the developer could be kept in the neighbourhood of any desired temperature. But the stains reappeared.

It had previously been suggested to me by Mr. Cullen, of Kodak, Ltd., that the trouble might be purely between the tap water and the gelatine, and on examining this possibility I discovered that the stain was controlled by the length of time the prints were wet. By rushing matters and shortening the period of wetness to the minimum, the stain was avoidable. But with large quantities of work it is often necessary, or at least convenient, to leave batches in overnight, and it is always necessary to wash large batches thoroughly. This was where the staining agency got to work. I eventually suspected germs to be the fundamental cause, and to test the theory I divided a pint of water between three dishes and doctored two of them with antiseptics, putting a trace of potass. permanganate in one and a few drops of mercuric chloride solution in the other. The third was untouched. A vignetted print was taken from the fixing bath and torn into three pieces, which, after a short wash, were put into the dishes, one in each, and left for twenty-four hours. The strips in the doctored dishes were still pure in the whites after this immersion, but the third one showed

signs of discolouration. A second test came out the same way, but as might be expected, no violent staining properties were in the water at the time they were desired, and so the tests were not as decisive as they might have been had the undoctored water stained more pronouncedly. However, it was decided to treat all water in which prints were left standing with a few drops of permanganate solution, and since then the trouble has not been in evidence.

I have since heard from Messrs. Kodak that the production of this particular stain is only possible when alum is in use, and, as a matter of fact, all the staining I had experienced was with prints that had been through hardening-fixing baths. I have since left prints overnight in untreated water without any sign of the trouble, the same prints being unhardened.

It appears, therefore, that organic matter in the water that is used for photography is capable of staining gelatine if allowed sufficient time to act, and that such action is dependent upon the gelatine having been previously treated with alum.

During the time that I experienced the staining I did not find negatives affected, but experience in past times leads me to believe that the same thing is possible with the gelatine coating on plates, though an observation of mine would suggest that plates are not so liable to it. The observation referred to is that the stain starts on the underside of the gelatine film, sometimes being quite distinct by transmitted light before appearing on the surface. With plates, the under side of the emulsion is, of course, more difficult to get at.

THERMIT.

PARIS NOTES.

Photographic Instruction in France.

FRANCE is one of the few countries which is without means for systematic instruction in photography or laboratories for research in photographic processes, if we except the small number of the latter supported by manufacturers of photographic materials or by cinematograph firms. Colonel Laussedat, the founder of photogrammetry, when director of the Conservatoire National des Arts et Metiers, attempted on several occasions to provide education in photography in this institution; and in order to convince the authorities of the importance of this undertaking he organised in 1891-1892, and again about 1905, a series of lessons, at each of which the attendance was greater than a large lecture hall could accommodate. His aim seemed to have been accomplished. Government grants were made in aid of his scheme, but at the last moment an outcry for economy caused their withdrawal.

It is true there are some courses of elementary instruction undertaken in various institutions for popular education or in some photographic societies, but they are almost exclusively for beginners in amateur photography. The Municipal School for the Book Industry (Ecole Estienne) in Paris provides a course of instruction in photo-mechanical processes for students of from 13 to 16 years of age, but its teaching is limited to the rudiments of the subject, and the small staff has neither time nor material resources for research in the improvement of the traditional empirical methods.

During the war some efforts were made, notably in Paris and Lyons, for the photographic training of wounded soldiers unable to follow their own occupations, but these attempts at professional instruction have been discontinued.

For a long time past the Chambres Syndicales (trade or professional associations) connected with photography have considered the establishment of a school of professional photography, the need of which becomes more and more felt, but their resources are unequal to the enterprise, and they have to deplore the complete indifference of public authorities or unacceptable offers of inadequate collaboration. The French official mind regards professional instruction only as free instruction, and makes any offer of assistance subject to this condition. Therefore, it seems that a French school of photography is likely to remain a chimerical project for a long time to come, unless it can be established under the stimulus of some active photographic personality, and, without relying on platonic expressions of support from public authorities, can be founded and maintained on a commercial basis. I am convinced that an attempt of this kind would soon become a success.

Slide Changing from the Platform.

The French Physical Society during the first few days of last month resumed its customary annual exhibition of new appliances and methods appertaining to scientific research, instruction in physics and to industrial application. These exhibitions, which formerly were one of the most welcome activities of the Society, were discontinued during the war. Last month a new application of photography was represented by the method of photo-stereo-synthesis, devised by M. Lumière, and already described in the "B.J." of February 25 last, p. 110. The specimens were somewhat different from those previously shown. The portraits, in natural size, are now formed by seven component images, the respective distances of which increase in geometrical progression, thus giving in greater detail the most important parts of the face. Some very interesting examples of X-ray work on Eastman duplitized film by Mr. N. E. Luboshey were exhibited personally by the author, who communicated many practical details of his method of working. The microphotometer, designed by Professors Fabry and Buisson, for the measurement of photographic densities of such small areas of negatives as those of the spectra of rare elements, was shown by its constructor, M. A. Jobin. M. G. Massiot, a maker of scientific instruments, well known for his projection apparatus, showed an automatic projection lantern for use in class instruction. The slides are arranged beforehand in a magazine in the order in which they are to be shown, and are brought in turn into the projection stage by means of an electrical mechanism operated by the teacher or lecturer.

Cinematography in Colours.

A new attempt to apply one of the oldest processes of cinematography in three colours has recently been made by M. Herault. The images are registered successively on the same film by means of one lens, in the beam from which a disc containing the three filters is rotated, as in the ordinary cinematograph apparatus. The positive film is shown by an ordinary projector provided also with a rotating filter disc, the colours being combined by the successive impulses upon the spectator's eyes. Although M. Herault takes and projects his views at the rate of about 30 per second, and although in the picture play which was shown the actors had almost entirely avoided all relatively rapid movement, there was a most unpleasing fringe of green and red around the outlines of moving objects. On the other hand, for still subjects, or for portraits taken close up, the colour rendering was very satisfactory; nevertheless, the successive projection of contrasting colours produces a species of colour flicker which is somewhat fatiguing to the eyes.

The process is certainly far inferior to the Gaumont three-colour cinematography shown in the Hippodrome in Paris. In this process the three colour-sensation images are made simultaneously on a single film by means of three lenses, each provided with its appropriate filter. The three positives are then

projected simultaneously in register by means of a three-lens projector, each objective of which is provided with its appropriate colour filter. Effects of parallax are, of course, inherent in this process, in the case of subjects containing widely separated planes, but by avoiding such subjects and by ensuring exact register of the chief part of the subject, the parallax errors pass unnoticed. Some years ago M. P. Ulysse demonstrated a somewhat similar process in London; in spite of some defects of detail, which might readily be overcome, it was greatly superior to the process first mentioned in this paragraph.

Experiments on Desensitisers.

MM. A. and L. Lumière and A. Seyewetz have carried out an extensive study of the desensitisation of photographic plates for the purpose of discovering the other types of dyes and descriptions of both organic and mineral compounds which possess properties similar to those of the safranines. After having found that almost all the red or violet safranines give results similar to those obtained with pheno-safranine—that is to say, a reduction of sensitiveness in the blue region of the spectrum to about 1-800th, and complete desensitisation in other regions—they have found that aurantia is also a valuable desensitiser. It is less active than the safranines for orthochromatic or panchromatic plates, but of ample effect for even the most rapid ordinary plates and more easily washed out of the film than safranine. Among other dyes and colourless organic compounds of small practical interest they have found that neutral chromates, e.g., neutral potassium chromate, have desensitising properties—not, it is true, of a high order, since the sensitiveness throughout the spectrum is reduced to about 1-40th—but sufficient for use with bromide papers, and sufficient also for Autochrome plates when the object is simply to permit a brighter dark-room illumination and not to carry out development by transmitted light. Immersion of the paper or film for about a minute in a solution of neutral chromate suffices for desensitisation, and there is no staining of the paper or gelatine.

Stereoscopic Projection.

At the meeting of the French Photographic Society, held on April 22 last, a very interesting experiment in stereoscopic projection was made by M. Maurice Miet. He used a positive transparency made from the ordinary stereoscopic negative without the usual transposition. The image to be viewed by the left eye was projected on the right of the screen, and that to be viewed by the right eye, to the left. Stereoscopic viewing was obtained by crossing the directions of the ocular axes, namely, by looking at an object held for an instant at a short distance from the eyes. The new feature, in this experiment of M. Miet's, consisted in using as this object a card in which a square aperture was cut. A card of about half-plate size, with a square hole about 2 by 2 inches, serves well when held in front of the eyes at about 1-20th of the distance of the eyes from the projection screen. Whilst this mask cuts off the two side images, which, in this mode of viewing usually enclose the central stereoscopic image formed by the superimposition of the two component images, it considerably reduces the strain of observation, and avoids the sudden separation of the superimposed images which readily takes place when this simple accessory is not used. The effect of relief produced in this way is positively striking, but is seen only by persons who have acquired the ability to see stereoscopically without a stereoscope. Moreover, it imposes a strain on the muscles of the eyes, as does the use of an improperly adjusted stereoscope. The members of the audience who, in these circumstances, saw the stereoscopic effect, were asked to raise their hands and were found to be in a minority. But there is no need to resort to projection in order to ascertain the absence of the power of seeing stereoscopically of the many people who prefer to close one eye when asked to look into a stereoscope. The process is so simple that it can easily be experimented with, and I think that its repetition would interest many photographic societies so long as the exercise is limited to not more than a dozen views on the screen, so that there may be no excessive strain of the eyes.

Film Negative Cards.

The continued high cost of glass is necessarily keeping the price of plates at a level which renders their use prohibitive for amateurs of moderate means. And, as in France, the great majority of amateur cameras are for the use of plates, much ingenuity is being devoted to finding a cheaper substitute. The latest new comer in this field is the Folio-Brom, placed on the market by the firm of Guilleminot. It consists of a card of about the thickness ordinarily used for sensitive postcards on which is a film of aceto-cellulose bearing a rapid orthochromatic emulsion of about 400 H. and D. In using these cards in dark-slides, a backing card of about 1/16 in. thickness serves to keep them in place and in register. After development, fixing, washing and drying, a strip is cut off round the card to the width of about 1-16th of an inch, using a pair of scissors or a sharp knife, and the film negative can then be stripped off.

Instruction by Cinematograph.

For several years past efforts have been made in France to utilise the cinematograph in teaching of various kinds, from elementary instruction to the technical and science courses in the Universities, where already the cinematograph is employed as an instrument of record and research. That these efforts are gaining ground is shown by the facts that the Paris municipality has just voted funds for the purchase of projectors and films, and that the Ministry of Public Instruction has added to the numerous sets of lantern-slides, which it circulates, a number of films for exhibition in the public schools. The free circulation of these collections by the postal service is a great boon to provincial schools, whilst many municipal authorities are beginning to acquire projection equipment.

Among the most recent attempts to apply the cinematograph to teaching must be mentioned the use which is being made of it by M. A. Bruneau, professor in the School of Decorative Arts in Paris. M. Bruneau makes his students draw their designs immediately after the exhibition of suitably-chosen films, which are shown at a slow speed so as to permit of analysis of the movements and postures in walking, dancing, sports and industrial occupations. The students are thus caused to select from their observation of the film the phases of movement which lend themselves to use in decorative compositions.

A Rapid Cinematograph Film Printer.
